QUICK REFERENCE (QR) VIDEO ACCESS

The images below are QR codes. Each code corresponds to a video from the *Goldman-Cecil Medicine 25* collection. For fast and easy video access, right from your mobile device, follow these instructions. The videos are also available on Expertconsult.com.

What You Need

- **A mobile device, such as a smartphone or tablet, equipped with a camera and Internet access**
- **A QR code reader application (If you do not already have a reader installed on your mobile device, look for free versions in your app store.)**

How It Works

- **Open the QR code reader application on your mobile device.**
- **Point the device's camera at the code and scan.**
- **Each code opens an individual video player for instant viewing—no log-on required.**

Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

PREFACE

In the 90 years since the first edition of the *Cecil Textbook of Medicine* was published, almost everything we know about internal medicine has changed. Progress in medical science is now occurring at an ever-accelerating pace, and it is doing so within the framework of transformational changes in clinical practice and the delivery of health care at individual, social, and global levels. This textbook and its associated electronic products incorporate the latest medical knowledge in multiple formats that should appeal to students and seasoned practitioners regardless of how they prefer to access this rapidly changing information.

Even as *Cecil*'s specific information has changed, however, we have remained true to the tradition of a comprehensive textbook of medicine that carefully explains the *why* (the underlying pathophysiology of disease) and the *how* (now expected to be evidence-based from randomized controlled trials and meta-analyses). Descriptions of physiology and pathophysiology include the latest genetic advances in a practical format that strives to be useful to the nonexpert. Medicine has entered an era when the acuity of illness and the limited time available to evaluate a patient have diminished the ability of physicians to satisfy their intellectual curiosity. As a result, the acquisition of information, quite easily achieved in this era, is often confused with knowledge. We have attempted to address this dilemma with a textbook that not only informs but also stimulates new questions and gives a glimpse of the future path to new knowledge. Grade A evidence is specifically highlighted in the text and referenced at the end of each chapter. In addition to the information provided in the textbook, the *Cecil* website supplies expanded content and functionality. In many cases, the full articles referenced in each chapter can be accessed from the *Cecil* website. The website is also continuously updated to incorporate subsequent Grade A information, other evidence, and new discoveries.

The sections for each organ system begin with a chapter that summarizes an approach to patients with key symptoms, signs, or laboratory abnormalities associated with dysfunction of that organ system. As summarized in E-Table 1-1, the text specifically provides clear, concise information regarding how a physician should approach more than 100 common symptoms, signs, and laboratory abnormalities, usually with a flow diagram, a table, or both for easy reference. In this way, *Cecil* remains a comprehensive text to guide diagnosis and therapy, not only for patients with suspected or known diseases but also for patients who may have undiagnosed abnormalities that require an initial evaluation.

Just as each edition brings new authors, it also reminds us of our gratitude to past editors and authors. Previous editors of *Cecil* include a short but remarkably distinguished group of leaders of American medicine: Russell Cecil, Paul Beeson, Walsh McDermott, James Wyngaarden, Lloyd H. Smith, Jr., Fred Plum, J. Claude Bennett, and Dennis Ausiello. As we welcome new associate editors—Mary K. Crow, James H. Doroshow, and Allen M. Spiegel—we also express our appreciation to William P. Arend, James O. Armitage, David R. Clemmons, and other associate editors from the previous editions on whose foundation we have built. Our returning associate editors—Jeffrey M. Drazen, Robert C. Griggs, Donald W. Landry, Wendy Levinson, Anil K. Rustgi, and W. Michael Scheld—continue to make critical contributions to the selection of authors and the review and approval of all manuscripts. The editors, however, are fully responsible for the book as well as the integration among chapters.

The tradition of *Cecil* is that all chapters are written by distinguished experts in each field. We are also most grateful for the editorial assistance in New York of Maribel Lim and Silva Sergenian. These individuals and others in our offices have shown extraordinary dedication and equanimity in working with authors and editors to manage the unending flow of manuscripts, figures, and permissions. We also thank Cassondra Andreychik, Ved Bhushan Arya, Cameron Harrison, Karen Krok, Robert J. Mentz, Gaétane Nocturne, Patrice Savard, Senthil Senniappan, Tejpratap Tiwari, and Sangeetha Venkatarajan, who contributed to various chapters, and we mourn the passing of Morton N. Swartz, MD, co-author of the chapter on "Meningitis: Bacterial, Viral, and Other" and Donald E. Low, MD, author of the chapter "Nonpneumococcal Streptococcal Infections, Rheumatic Fever." At Elsevier, we are most indebted to Kate Dimock and Maureen Iannuzzi, and also thank Maria Holman, Gabriela Benner, Cindy Thoms, Anne Altepeter, Linda McKinley, Paula Catalano, and Kristin Koehler, who have been critical to the planning and production process under the guidance of Mary Gatsch. Many of the clinical photographs were supplied by Charles D. Forbes and William F. Jackson, authors of *Color Atlas and Text of Clinical Medicine*, Third Edition, published in 2003 by Elsevier Science Ltd. We thank them for graciously permitting us to include their pictures in our book. We have been exposed to remarkable physicians in our lifetimes and would like to acknowledge the mentorship and support of several of those who exemplify this paradigm—Eugene Braunwald, Lloyd H. Smith, Jr., Frank Gardner, and William Castle. Finally, we would like to thank the Goldman family—Jill, Jeff, Abigail, Mira, Samuel, Daniel, Robyn, Tobin, and Dashel—and the Schafer family—Pauline, Eric, Melissa, Nathaniel, Pam, John, Evan, Samantha, Kate, and Sean, for their understanding of the time and focus required to edit a book that attempts to sustain the tradition of our predecessors and to meet the needs of today's physician.

Professor of Medicine, Director, Hematopoietic Cellular Therapy Program, Section of Hematology and Oncology, Department of Medicine, University of Chicago, Chicago, Illinois
Hematopoietic Stem Cell Transplantation

Bruce R. Bistrian, MD, PhD, MPH
Professor of Medicine, Beth Israel Deaconess Medical Center; Professor of Medicine, Harvard Medical School, Boston, Massachusetts
Nutritional Assessment

Joseph J. Biundo, MD
Clinical Professor of Medicine, Tulane Medical Center, New Orleans, Louisiana
Bursitis, Tendinitis, and Other Periarticular Disorders and Sports Medicine

Adrian R. Black, PhD
Assistant Professor, Director of Tissue Sciences for the Eppley Institute, The Eppley Institute for Research in Cancer and Allied Diseases, University of Nebraska Medical Center, Omaha, Nebraska
Cancer Biology and Genetics

Charles D. Blanke, MD
Professor of Medicine, Oregon Health and Science University, Portland, Oregon
Neoplasms of the Small and Large Intestine

Joel N. Blankson, MD, PhD
Associate Professor, Johns Hopkins University School of Medicine, Baltimore, Maryland
Immunopathogenesis of Human Immunodeficiency Virus Infection

Martin J. Blaser, MD
Muriel and George Singer Professor of Medicine, Professor of Microbiology, Director, Human Microbiome Program, New York University Langone Medical Center, New York, New York
Acid Peptic Disease; Human Microbiome

William A. Blattner, MD
Professor and Associate Director, Institute of Human Virology, School of Medicine, University of Maryland; Professor of Medicine, School of Medicine, University of Maryland; Professor and Head, Division of Cancer Epidemiology, Department of Epidemiology and Public Health, School of Medicine, University of Maryland, Baltimore, Maryland
Retroviruses Other Than Human Immunodeficiency Virus

Thomas P. Bleck, MD
Professor of Neurological Sciences, Neurosurgery, Internal Medicine, and Anesthesiology, Associate Chief Medical Officer (Critical Care), Rush Medical College, Chicago, Illinois
Arboviruses Affecting the Central Nervous System

Joel A. Block, MD
The Willard L. Wood MD Professor and Director, Division of Rheumatology, Rush University Medical Center, Chicago, Illinois
Osteoarthritis

Henk Blom, MD
Laboratory of Clinical Biochemistry and Metabolism, Department of General Pediatrics, Adolescent Medicine and Neonatology, University Medical Centre Freiburg, Head of Laboratory/Clinical Biochemical Geneticist, Freiburg, Germany
Homocystinuria and Hyperhomocysteinemia

Olaf A. Bodamer, MD
Medical Genetics, University of Miami Hospital, Miami, Florida
Approach to Inborn Errors of Metabolism

William E. Boden, MD
Professor of Medicine, Albany Medical College; Chief of Medicine, Albany Stratton VA Medical Center; Vice-Chairman, Department of Medicine, Albany Medical Center, Albany, New York
Angina Pectoris and Stable Ischemic Heart Disease

Jean Bolognia, MD
Professor of Dermatology, Yale Medical School; Attending Physician, Yale-New Haven Hospital, New Haven, Connecticut
Infections, Hyperpigmentation and Hypopigmentation, Regional Dermatology, and Distinctive Lesions in Black Skin

Robert A. Bonomo, MD
Chief, Medical Service, Louis Stokes Cleveland VA Medical Center; Professor of Medicine, Pharmacology, Biochemistry, Molecular Biology, and Microbiology, Case Western Reserve University School of Medicine, Cleveland, Ohio
Diseases Caused by Acinetobacter and Stenotrophomonas Species

Larry Borish, MD
Professor of Medicine, Allergy, and Clinical Immunology, University of Virginia Health System, Charlottesville, Virgina
Allergic Rhinitis and Chronic Sinusitis

Patrick J. Bosque, MD
Associate Professor of Neurology, University of Colorado Denver School of Medicine; Neurologist, Denver Health Medical Center, Denver, Colorado
Prion Diseases

David J. Brenner, PhD, DSc
Higgins Professor of Radiation Biophysics, Center for Radiological Research, Columbia University Medical Center, New York, New York
Radiation Injury

Itzhak Brook, MD, MSc
Professor of Pediatrics and Medicine, Georgetown University, Georgetown University Medical Center, Washington, D.C.
Diseases Caused by Non–Spore-Forming Anaerobic Bacteria; Actinomycosis

Enrico Brunetti, MD
Assistant Professor of Infectious Diseases, University of Pavia; Attending Physician, Division of Infectious and Tropical Diseases, IRCCS San Matteo Hospital Foundation; Co-Director, WHO Collaborating Centre for Clinical Management of Cystic Echinococcosis, Pavia, Italy
Cestodes

David M. Buchner, MD, MPH
Shahid and Ann Carlson Khan Professor in Applied Health Sciences, Department of Kinesiology and Community Health, University of Illinois at Urbana-Champaign, Champaign, Illinois
Physical Activity

Pierre A. Buffet, MD, PhD
Research Unit Head, Erythrocyte Parasite Pathogenesis Research Team INSERM–University Paris 6, CIMI–Paris Research Center, University Pierre and Marie Curie; Associate Professor of Parasitology, Faculty of Medicine, University Pierre and Marie Curie, Pitié-Salpêtrière Hospital, Paris, France
Leishmaniasis

H. Franklin Bunn, MD
Professor of Medicine, Harvard Medical School; Physician, Brigham and Women's Hospital, Boston, Massachusetts
Approach to the Anemias

David A. Bushinsky, MD
John J. Kuiper Distinguished Professor of Medicine, Chief, Nephrology Division, University of Rochester School of Medicine; Associate Chair for Academic Affairs in Medicine, University of Rochester Medical Center, Rochester, New York
Nephrolithiasis

Vivian P. Bykerk, MD
Associate Professor of Medicine, Weill Cornell Medical College; Associate Attending Physician, Hospital for Special Surgery, New York, New York
Approach to the Patient with Rheumatic Disease

Peter A. Calabresi, MD
Professor of Neurology and Director of the Richard T. Johnson Division of Neuroimmunology and Neuroinfectious Diseases, Johns Hopkins University; Director of the Multiple Sclerosis Center, Johns Hopkins Hospital, Baltimore, Maryland
Multiple Sclerosis and Demyelinating Conditions of the Central Nervous System

David P. Calfee, MD, MS
Associate Professor of Medicine and Healthcare Policy and Research, Weill Cornell Medical College; Chief Hospital Epidemiologist, New York-Presbyterian Hospital/Weill Cornell Medical Center, New York, New York
Prevention and Control of Health Care–Associated Infections

Douglas Cameron, MD, MBA
Professor of Ophthalmology and Visual Neurosciences, University of Minnesota, Minneapolis, Minnesota
Diseases of the Visual System

Michael Camilleri, MD
Atherton and Winifred W. Bean Professor, Professor of Medicine, Pharmacology, and Physiology, College of Medicine, Mayo Clinic, Consultant, Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, Minnesota
Disorders of Gastrointestinal Motility

Grant W. Cannon, MD
Thomas E. and Rebecca D. Jeremy Presidential Endowed Chair for Arthritis Research, Associate Chief of Staff for Academic Affiliations, George E. Wahlen VA Medical Center, Salt Lake City, Utah
Immunosuppressing Drugs Including Corticosteroids

Maria Domenica Cappellini, MD
Professor of Internal Medicine, University of Milan, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy
The Thalassemias

Blase A. Carabello, MD
Professor of Medicine, Chairman, Department of Cardiology, Mount Sinai Beth Israel Heart Institute, New York, New York
Valvular Heart Disease

Edgar M. Carvalho, MD
Professor of Medicine and Clinical Immunology, Faculdade de Medicina da Bahia, Universidade Federal da Bahia and Escola Bahiana de Medicina e Saúde Pública, Salvador, Bahia, Brazil
Schistosomiasis (Bilharziasis)

William H. Catherino, MD, PhD
Professor and Research Head, Department of Obstetrics and Gynecology, Uniformed Services University of the Health Sciences Division of Reproductive Endocrinology and Infertility; Program in Reproductive and Adult Endocrinology, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland
Ovaries and Development; Reproductive Endocrinology and Infertility

Jane A. Cauley, DrPH
Professor of Epidemiology, University of Pittsburgh Graduate School of Public Health, Vice Chair of the Department of Epidemiology, Pittsburgh, Pennsylvania
Epidemiology of Aging: Implications of the Aging of Society

Naga P. Chalasani, MD
David W. Crabb Professor and Director, Division of Gastroenterology and Hepatology, Indiana University School of Medicine, Indianapolis, Indiana
Alcoholic and Nonalcoholic Steatohepatitis

Henry F. Chambers, MD
Professor of Medicine, University of California San Francisco School of Medicine; Director, Clinical Research Services, Clinical and Translational Sciences Institute, San Francisco, California
Staphylococcal Infections

William P. Cheshire, Jr., MD
Professor of Neurology, Mayo Clinic, Jacksonville, Florida
Autonomic Disorders and Their Management

Ilseung Cho, MD, MS
Assistant Professor of Medicine, Division of Gastroenterology, Department of Medicine, New York University, New York, New York
Human Microbiome

Arun Chockalingam, PhD
Professor of Epidemiology and Global Health, Director, Office of Global Health Education and Training; Dalla Lana Faculty of Public Health, University of Toronto, Toronto, Ontario, Canada
Global Health

David C. Christiani, MD
Professor of Medicine, Harvard Medical School; Physician, Pulmonary and Critical Care, Massachusetts General Hospital; Elkan Blout Professor of Environmental Genetics, Environmental Health, Harvard School of Public Health, Boston, Massachusetts
Physical and Chemical Injuries of the Lung

David H. Chu, MD, PhD
Director, Contact Dermatitis, Division of Dermatology and Cutaneous Surgery, Scripps Clinic Medical Group, La Jolla, California
Structure and Function of the Skin

Theodore J. Cieslak, MD
Pediatric Infectious Diseases, Clinical Professor of Pediatrics, University of Texas Health Science Center at San Antonio; Department of Pediatrics, Fort Sam Houston, Texas
Bioterrorism

Carolyn Clancy, MD
Interim Under Secretary for Health, Veterans Administration, Washington, D.C.
Measuring Health and Health Care

David R. Clemmons, MD
Kenan Professor of Medicine, University of North Carolina School of Medicine; Attending Physician, Medicine, UNC Hospitals, Chapel Hill, North Carolina
Approach to the Patient with Endocrine Disease

David Cohen, MD
Professor of Medicine, Division of Nephrology; Medical Director, Kidney and Pancreas Transplantation, Columbia University Medical Center, New York, New York
Treatment of Irreversible Renal Failure

Jeffrey Cohen, MD
Chief, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland
Varicella-Zoster Virus (Chickenpox, Shingles)

Myron S. Cohen, MD
Associate Vice Chancellor for Global Health, Director, UNC Institute for Global Health and Infectious Diseases, Chief, Division of Infectious Diseases, Yeargan-Bate Eminent Professor of Medicine, Microbiology, and Immunology and Epidemiology, Chapel Hill, North Carolina
Approach to the Patient with a Sexually Transmitted Infection; Prevention of Human Immunodeficiency Virus Infection

Steven P. Cohen, MD
Professor of Anesthesiology and Critical Care Medicine and Physical Medicine and Rehabilitation, Johns Hopkins School of Medicine, Baltimore, Maryland, and Uniformed Services University of the Health Sciences, Bethesda, Maryland; Director, Pain Research, Walter Reed National Military Medical Center, Bethesda, Maryland
Pain

Steven L. Cohn, MD
Professor of Clinical Medicine, University of Miami Miller School of Medicine; Medical Director, UHealth Preoperative Assessment Center; Director, Medical Consultation Service, University of Miami Hospital, Miami, Florida
Preoperative Evaluation

Robert Colebunders, MD
Emeritus Professor, Institute of Tropical Medicine, Antwerp, Belgium
Immune Reconstitution Inflammatory Syndrome in HIV/AIDS

Joseph M. Connors, MD
Clinical Professor, University of British Columbia; Clinical Director, BC Cancer Agency Centre for Lymphoid Cancer, Vancouver, British Columbia, Canada
Hodgkin Lymphoma

Deborah J. Cook, MD, MSc
Professor of Medicine, Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, Ontario, Canada
Approach to the Patient in a Critical Care Setting

Kenneth H. Cowan, MD, PhD
Director, Fred & Pamela Buffett Cancer Center; Director, The Eppley Institute for Research in Cancer and Allied Diseases; Professor of Medicine, University of Nebraska Medical Center, Omaha, Nebraska
Cancer Biology and Genetics

Joseph Craft, MD
Paul B. Beeson Professor of Medicine and Immunobiology, Section Chief, Rheumatology, Program Director, Investigative Medicine, Department of Internal Medicine, Yale University School of Medicine, New Haven, Connecticut
The Adaptive Immune Systems

Jill Patricia Crandall, MD
Professor of Clinical Medicine, Division of Endocrinology and Diabetes Research Center, Albert Einstein College of Medicine, Bronx, New York
Diabetes Mellitus

Simon L. Croft, BSc, PhD
Professor of Parasitology, Faculty of Infectious and Tropical Diseases, London School of Hygiene and Tropical Medicine, London, United Kingdom
Leishmaniasis

Kristina Crothers, MD
Associate Professor, Department of Medicine, Division of Pulmonary and Critical Care, University of Washington School of Medicine, Seattle, Washington
Pulmonary Manifestations of Human Immunodeficiency Virus and Acquired Immunodeficiency Syndrome

Mary K. Crow, MD
Joseph P. Routh Professor of Rheumatic Diseases in Medicine, Weill Cornell Medical College; Physician in Chief and Benjamin M. Rosen Chair in Immunology and Inflammation Research, Hospital for Special Surgery, New York, New York
The Innate Immune Systems; Approach to the Patient with Rheumatic Disease; Systemic Lupus Erythematosus

John A. Crump, MB ChB, MD, DTM&H
McKinlay Professor of Global Health, Centre for International Health, University of Otago, Dunedin, New Zealand
Salmonella Infections (Including Enteric Fever)

Mark R. Cullen, MD
Professor of Medicine, Department of Medicine, Stanford University School of Medicine, Stanford, California
Principles of Occupational and Environmental Medicine

Charlotte Cunningham-Rundles, MD, PhD
Professor of Medicine and Pediatrics, Icahn School of Medicine at Mount Sinai, New York, New York
Primary Immunodeficiency Diseases

Inger K. Damon, MD, PhD
Director, Division of High Consequence Pathogens and Pathology, Centers for Disease Control and Prevention, Atlanta, Georgia
Smallpox, Monkeypox, and Other Poxvirus Infections

Troy E. Daniels, DDS, MS
Professor Emeritus of Oral Pathology and Pathology, University of California San Francisco, San Francisco, California
Diseases of the Mouth and Salivary Glands

Nancy E. Davidson, MD
Hillman Professor of Oncology, University of Pittsburgh; Director, University of Pittsburgh Cancer Institute and UPMC CancerCenter, Pittsburgh, Pennsylvania
Breast Cancer and Benign Breast Disorders

Lisa M. DeAngelis, MD
Chair, Department of Neurology, Memorial Sloan-Kettering Cancer Center; Professor of Neurology, Weill Cornell Medical College, New York, New York
Tumors of the Central Nervous System

Malcolm M. DeCamp, MD
Fowler McCormick Professor of Surgery, Feinberg School of Medicine, Northwestern University; Chief, Division of Thoracic Surgery, Northwestern Memorial Hospital, Chicago, Illinois
Interventional and Surgical Approaches to Lung Disease

Carlos del Rio, MD
Hubert Professor and Chair and Professor of Medicine, Hubert Department of Global Health, Rollins School of Public Health and Department of Medicine, Emory University School of Medicine, Atlanta, Georgia
Prevention of Human Immunodeficiency Virus Infection

Patricia A. Deuster, PhD, MPH
Professor and Director, Consortium for Health and Military Performance, Department of Military and Emergency Medicine, Uniformed Services University of the Health Sciences, Bethesda, Maryland
Rhabdomyolysis

Robert B. Diasio, MD
William J. and Charles H. Mayo Professor, Molecular Pharmacology and Experimental Therapeutics and Oncology, Mayo Clinic, Rochester, Minnesota
Principles of Drug Therapy

David J. Diemert, MD
Associate Professor, Department of Microbiology, Immunology, and Tropical Medicine, School of Medicine and Health Sciences, The George Washington University, Washington, D.C.
Intestinal Nematode Infections; Tissue Nematode Infections

Kathleen B. Digre, MD
Professor of Neurology, Ophthalmology, Director, Division of Headache and Neuro-Ophthalmology, University of Utah, Salt Lake City, Utah
Headaches and Other Head Pain

James H. Doroshow, MD
Bethesda, Maryland
Approach to the Patient with Cancer; Malignant Tumors of Bone, Sarcomas, and Other Soft Tissue Neoplasms

John M. Douglas, Jr., MD
Executive Director, Tri-County Health Department, Greenwood Village, Colorado
Papillomavirus

Jeffrey M. Drazen, MD
Distinguished Parker B. Francis Professor of Medicine, Harvard Medical School; Senior Physician, Brigham and Women's Hospital, Boston, Massachusetts
Asthma

Stephen C. Dreskin, MD, PhD
Professor of Medicine and Immunology, Division of Allergy and Clinical Immunology, Department of Medicine, University of Colorado Denver, School of Medicine, Aurora, Colorado
Urticaria and Angioedema

W. Lawrence Drew, MD, PhD
Professor Emeritus, Laboratory Medicine and Medicine, University of California San Francisco, San Francisco, California
Cytomegalovirus

George L. Drusano, MD
Professor and Director, Institute for Therapeutic Innovation, College of Medicine, University of Florida, Lake Nona, Florida
Antibacterial Chemotherapy

Thomas D. DuBose, Jr., MD
Emeritus Professor of Internal Medicine and Nephrology, Wake Forest School of Medicine, Winston-Salem, North Carolina
Vascular Disorders of the Kidney

F. Daniel Duffy, MD
Professor of Internal Medicine and Steve Landgarten Chair in Medical Leadership, School of Community Medicine, University of Oklahoma College of Medicine, Tulsa, Oklahoma
Counseling for Behavior Change

Herbert L. DuPont, MD, MACP
Mary W. Kelsey Chair and Director, Center for Infectious Diseases, University of Texas School of Public Health; H. Irving Schweppe Chair of Internal Medicine and Vice Chairman, Department of Medicine, Baylor College of Medicine; Chief of Internal Medicine, St. Luke's Hospital System, Houston, Texas
Approach to the Patient with Suspected Enteric Infection

Madeleine Duvic, MD
Professor and Deputy Chairman, Department of Dermatology, The University of Texas MD Anderson Cancer Center, Houston, Texas
Urticaria, Drug Hypersensitivity Rashes, Nodules and Tumors, and Atrophic Diseases

Kathryn M. Edwards, MD
Sarah H. Sell and Cornelius Vanderbilt Chair in Pediatrics, Vanderbilt University School of Medicine; Director, Vanderbilt Vaccine Research Program, Monroe Carrell Jr. Children's Hospital at Vanderbilt, Nashville, Tennessee
Parainfluenza Viral Disease

N. Lawrence Edwards, MD
Professor of Medicine, Vice Chairman, Department of Medicine, University of Florida; Chief, Section of Rheumatology, Medical Service, Malcom Randall Veterans Affairs Medical Center, Gainesville, Florida
Crystal Deposition Diseases

Lawrence H. Einhorn, MD
Distinguished Professor, Department of Medicine, Division of Hematology/Oncology, Livestrong Foundation Professor of Oncology, Indiana University School of Medicine, Indianapolis, Indiana
Testicular Cancer

Ronald J. Elin, MD, PhD
A.J. Miller Professor and Chairman, Department of Pathology and Laboratory Medicine, University of Louisville School of Medicine, Louisville, Kentucky
Reference Intervals and Laboratory Values

George M. Eliopoulos, MD
Professor of Medicine, Harvard Medical School; Physician, Division of Infectious Diseases, Beth Israel Deaconess Medical Center, Boston, Massachusetts
Principles of Anti-Infective Therapy

Perry Elliott, MD
Professor in Inherited Cardiovascular Disease, Institute of Cardiovascular Science, University College London, London, United Kingdom
Diseases of the Myocardium and Endocardium

Jerrold J. Ellner, MD
Professor of Medicine, Boston University School of Medicine; Chief, Section of Infectious Diseases, Boston Medical Center, Boston, Massachusetts
Tuberculosis

Dirk M. Elston, MD
Director, Ackerman Academy of Dermatopathology, New York, New York
Arthropods and Leeches

Ezekiel J. Emanuel, MD, PhD
Vice Provost for Global Initiatives, Diane V.S. Levy and Robert M. Levy University Professor, Chair, Department of Medical Ethics and Health Policy, University of Pennsylvania, Philadelphia, Pennsylvania
Bioethics in the Practice of Medicine

Joel D. Ernst, MD
Director, Division of Infectious Diseases and Immunology, Jeffrey Bergstein Professor of Medicine, Professor of Medicine, Pathology, and Microbiology, New York University School of Medicine; Attending Physician, New York University Langone Medical Center, New York, New York
Leprosy (Hansen Disease)

Gregory T. Everson, MD
Professor of Medicine, Director of Hepatology, University of Colorado School of Medicine, Aurora, Colorado
Hepatic Failure and Liver Transplantation

Amelia Evoli, MD
Associate Professor of Neurology, Catholic University, Agostino Gemelli University Hospital, Rome, Italy
Disorders of Neuromuscular Transmission

Douglas O. Faigel, MD
Professor of Medicine, Mayo Clinic, Chair, Division of Gastroenterology and Hepatology, Scottsdale, Arizona
Neoplasms of the Small and Large Intestine

Matthew E. Falagas, MD, MSc, DSc
Director, Alfa Institute of Biomedical Sciences, Athens, Greece; Adjunct Associate Professor of Medicine, Tufts University School of Medicine, Boston, Massachusetts; Chief, Department of Medicine and Infectious Diseases, Iaso General Hospital, Iaso Group, Athens, Greece
Pseudomonas and Related Gram-Negative Bacillary Infections

Gary W. Falk, MD, MS
Professor of Medicine, Division of Gastroenterology, University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania
Diseases of the Esophagus

Gene Feder, MBBS, MD
Professor, Centre for Academic Primary Care, School of Social and Community Medicine, University of Bristol; General Practitioner, Helios Medical Centre, Bristol, United Kingdom
Intimate Partner Violence

David J. Feller-Kopman, MD
Director, Bronchoscopy and Interventional Pulmonology, Associate Professor of Medicine, The Johns Hopkins University, Baltimore, Maryland
Interventional and Surgical Approaches to Lung Disease

Gary S. Firestein, MD
Dean and Associate Vice Chancellor of Translational Medicine, University of California San Diego School of Medicine, La Jolla, California
Mechanisms of Inflammation and Tissue Repair

Glenn I. Fishman, MD
Director, Leon H. Charney Division of Cardiology, Vice-Chair for Research, Department of Medicine, William Goldring Professor of Medicine, New York University School of Medicine, New York, New York
Principles of Electrophysiology

Lee A. Fleisher, MD
Robert D. Dripps Professor and Chair, Anesthesiology and Critical Care, Professor of Medicine, University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania
Overview of Anesthesia

Paul W. Flint, MD
Professor and Chair, Otolaryngology, Head and Neck Surgery, Oregon Health and Science University, Portland, Oregon
Throat Disorders

Evan L. Fogel, MD, MSc
Professor of Clinical Medicine, Indiana University School of Medicine, Indianapolis, Indiana
Diseases of the Gallbladder and Bile Ducts

Marsha D. Ford, MD
Adjunct Professor of Emergency Medicine, School of Medicine, University of North Carolina-Chapel Hill; Director, Carolinas Poison Center, Carolinas HealthCare System, Charlotte, North Carolina
Acute Poisoning

Chris E. Forsmark, MD
Professor of Medicine, Chief, Division of Gastroenterology, Hepatology, and Nutrition, University of Florida, Gainesville, Florida
Pancreatitis

Vance G. Fowler, Jr., MD, MHS
Professor of Medicine, Duke University Medical Center, Durham, North Carolina
Infective Endocarditis

Manuel A. Franco, MD, PhD
Director of Postgraduate Programs, School of Sciences, Pontificia Universidad Javeriana, Bogota, Colombia
Rotaviruses, Noroviruses, and Other Gastrointestinal Viruses

David O. Freedman, MD
Professor of Medicine and Microbiology, University of Alabama at Birmingham; Director, Gorgas Center for Geographic Medicine, Birmingham, Alabama
Approach to the Patient before and after Travel

Martyn A. French, MD
Professor in Clinical Immunology, School of Pathology and Laboratory Medicine, University of Western Australia, Perth, Australia
Immune Reconstitution Inflammatory Syndrome in HIV/AIDS

Karen Freund, MD, MPH
Professor of Medicine, Associate Director, Tufts Clinical and Translational Science Institute, Tufts University School of Medicine, Tufts Medical Center, Boston, Massachusetts
Approach to Women's Health

Cem Gabay, MD
Professor of Medicine, Head, Division of Rheumatology, University Hospitals of Geneva, Geneva, Switzerland
Biologic Agents

Kenneth L. Gage, PhD
Chief, Entomology and Ecology Activity, Centers for Disease Control and Prevention, Division of Vector-Borne Diseases, Bacterial Diseases Branch, Fort Collins, Colorado
Plague and Other Yersinia Infections

John N. Galgiani, MD
Professor of Medicine, Valley Fever Center for Excellence, University of Arizona, Tucson, Arizona
Coccidioidomycosis

Patrick G. Gallagher, MD
Professor of Pediatrics, Pathology, and Genetics, Yale University School of Medicine; Attending Physician, Yale–New Haven Hospital, New Haven, Connecticut
Hemolytic Anemias: Red Blood Cell Membrane and Metabolic Defects

Leonard Ganz, MD
Director of Cardiac Electrophysiology, Heritage Valley Health System, Beaver, Pennsylvania
Electrocardiography

Hasan Garan, MD
Director, Cardiac Electrophysiology, Dickinson W. Richards, Jr. Professor of Medicine, Columbia University Medical Center, New York, New York
Ventricular Arrhythmias

Guadalupe Garcia-Tsao, MD
Professor of Medicine, Yale University School of Medicine; Chief, Digestive Diseases, VA Connecticut Healthcare System, West Haven, Connecticut
Cirrhosis and Its Sequelae

William M. Geisler, MD, MPH
Professor of Medicine, University of Alabama at Birmingham, Birmingham, Alabama
Diseases Caused by Chlamydiae

Tony P. George, MD
Division of Brain and Therapeutics, Department of Psychiatry, University of Toronto; Schizophrenia Division, The Centre for Addiction and Mental Health, Toronto, Ontario, Canada
Nicotine and Tobacco

Lior Gepstein, MD, PhD
Edna and Jonathan Sohnis Professor in Medicine and Physiology, Rappaport Faculty of Medicine and Research Institute, Technion–Israel Institute of Technology, Rambam Health Care Campus, Haifa, Israel
Gene and Cell Therapy

Susan I. Gerber, MD
Team Lead, Respiratory Viruses/Picornaviruses, Division of Viral Diseases/Epidemiology Branch, National Center for Immunization and Respiratory Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia
Coronaviruses

Dale N. Gerding, MD
Professor of Medicine, Loyola University Chicago Stritch School of Medicine, Research Physician, Edward Hines, Jr. VA Hospital, Hines, Illinois
Clostridial Infections

Morie A. Gertz, MD
Consultant, Division of Hematology, Mayo Clinic, Rochester, Minnesota; Roland Seidler, Jr. Professor of the Art of Medicine in Honor of Michael D. Brennan, MD, Professor of Medicine, Mayo Clinic, College of Medicine, Rochester, Minnesota
Amyloidosis

Gordon D. Ginder, MD
Professor, Internal Medicine, Director, Massey Cancer Center, Virginia Commonwealth University, Richmond, Virginia
Microcytic and Hypochromic Anemias

Jeffrey S. Ginsberg, MD
Professor of Medicine, McMaster University, Member of Thrombosis and Atherosclerosis Research Institute, St. Joseph's Healthcare Hamilton, Hamilton, Ontario, Canada
Peripheral Venous Disease

Geoffrey S. Ginsburg, MD, PhD
Director, Duke Center for Applied Genomics and Precision Medicine; Professor of Medicine, Pathology and Biomedical Engineering, Duke University, Durham, North Carolina
Applications of Molecular Technologies to Clinical Medicine

Michael Glogauer, DDS, PhD
Professor, Faculty of Dentistry, University of Toronto, Toronto, Ontario, Canada
Disorders of Phagocyte Function

John W. Gnann, Jr., MD
Professor of Medicine, Department of Medicine, Division of Infectious Diseases, Medical University of South Carolina, Charleston, South Carolina
Mumps

Matthew R. Golden, MD, MPH
Professor of Medicine, University of Washington, Director, HIV/STD Program, Public Health–Seattle & King County, Seattle, Washington
Neisseria Gonorrhoeae *Infections*

Lee Goldman, MD
Harold and Margaret Hatch Professor, Executive Vice President and Dean of the Faculties of Health Sciences and Medicine, Chief Executive, Columbia University Medical Center, Columbia University, New York, New York
Approach to Medicine, the Patient, and the Medical Profession: Medicine as a Learned and Humane Profession; Approach to the Patient with Possible Cardiovascular Disease

Ellie J.C. Goldstein, MD
Clinical Professor of Medicine, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, California; Director, R.M. Alden Research Laboratory, Santa Monica, California
Diseases Caused by Non–Spore-Forming Anaerobic Bacteria

Larry B. Goldstein, MD
Professor of Neurology, Director, Duke Stroke Center, Neurology, Duke University; Staff Neurologist, Durham VA Medical Center, Durham, North Carolina
Approach to Cerebrovascular Diseases; Ischemic Cerebrovascular Disease

Lawrence T. Goodnough, MD
Professor of Pathology and Medicine, Stanford University; Director, Transfusion Service, Stanford University Medical Center, Stanford, California
Transfusion Medicine

Eduardo H. Gotuzzo, MD
Professor of Medicine, Director, Alexander von Humboldt Tropical Medicine Institute, Universidad Peruana Cayetano Heredia; Chief Physician, Department of Infectious, Tropical, and Dermatologic Diseases, National Hospital Cayetano Heredia, Lima, Peru
Cholera and Other Vibrio Infections; Liver, Intestinal, and Lung Fluke Infections

Deborah Grady, MD, MPH
Professor of Medicine, University of California San Francisco, San Francisco, California
Menopause

Leslie C. Grammer, MD
Professor of Medicine, Northwestern University Feinberg School of Medicine; Attending Physician, Northwestern Memorial Hospital, Chicago, Illinois
Drug Allergy

F. Anthony Greco, MD
Medical Director, Sarah Cannon Cancer Center, Nashville, Tennessee
Cancer of Unknown Primary Origin

Harry B. Greenberg, MD
Professor, Departments of Medicine and Microbiology and Immunology, Stanford University School of Medicine, Stanford, California
Rotaviruses, Noroviruses, and Other Gastrointestinal Viruses

Steven A. Greenberg, MD
Associate Professor of Neurology, Harvard Medical School; Associate Neurologist, Brigham and Women's Hospital, Boston, Massachusetts
Inflammatory Myopathies

Robert C. Griggs, MD
Professor of Neurology, Medicine, Pediatrics, and Pathology and Laboratory Medicine, University of Rochester School of Medicine and Dentistry, Rochester, New York
Approach to the Patient with Neurologic Disease

Lev M. Grinberg, MD, PhD
Professor, Chief, Department of Pathology, Ural Medical University; Chief Researcher of the Ural Scientific Research Institute of Phthisiopulmonology, Chief Pathologist of Ekaterinburg, Ekaterinburg, Russia
Anthrax

Daniel Grossman, MD
Vice President for Research, Ibis Reproductive Health, Oakland, California; Assistant Clinical Professor, Bixby Center for Global Reproductive Health, Department of Obstetrics, Gynecology and Reproductive Sciences, University of California San Francisco, San Francisco, California
Contraception

Lisa M. Guay-Woodford, MD
Hudson Professor of Pediatrics, The George Washington University; Director, Center for Translational Science, Director, Clinical and Translational Institute at Children's National, Children's National Health System, Washington, D.C.
Hereditary Nephropathies and Developmental Abnormalities of the Urinary Tract

Richard L. Guerrant, MD
Thomas H. Hunter Professor of International Medicine, Founding Director, Center for Global Health, Division of Infectious Diseases and International Health, University of Virginia School of Medicine, University of Virginia Health Sciences Center, Charlottesville, Virginia
Cryptosporidiosis

Roy M. Gulick, MD, MPH
Gladys and Roland Harrison Professor of Medicine, Medicine/Infectious Diseases, Weill Cornell Medical College; Attending Physician, New York–Presbyterian Hospital, New York, New York
Antiretrovial Therapy of HIV/AIDS

Klaus D. Hagspiel, MD
Professor of Radiology, Medicine, and Pediatrics, Chief, Noninvasive Cardiovascular Imaging, University of Virginia Health System, Charlottesville, Virginia
Noninvasive Cardiac Imaging

John D. Hainsworth, MD
Chief Scientific Officer, Sarah Cannon Research Institute, Nashville, Tennessee
Cancer of Unknown Primary Origin

Anders Hamsten, MD, PhD
Professor of Cardiovascular Diseases, Center for Molecular Medicine and Department of Cardiology, Karolinska University Hospital, Department of Medicine, Karolinska Institute, Stockholm, Sweden
Atherosclerosis, Thrombosis, and Vascular Biology

Kenneth R. Hande, MD
Professor of Medicine and Pharmacology, Vanderbilt/Ingram Cancer Center, Vanderbilt University School of Medicine, Nashville, Tennessee
Neuroendocrine Tumors and the Carcinoid Syndrome

H. Hunter Handsfield, MD
Professor Emeritus of Medicine, University of Washington Center for AIDS and STD, Seattle, Washington
Neisseria Gonorrhoeae *Infections*

Göran K. Hansson, MD, PhD
Professor of Cardiovascular Research, Center for Molecular Medicine at Karolinska University Hospital, Department of Medicine, Karolinska Institute, Stockholm, Sweden
Atherosclerosis, Thrombosis, and Vascular Biology

Raymond C. Harris, MD
Professor of Medicine, Ann and Roscoe R. Robinson Chair in Nephrology, Chief, Division of Nephrology, Vanderbilt University School of Medicine, Nashville, Tennessee
Diabetes and the Kidney

Stephen Crane Hauser, MD
Associate Professor of Medicine, Internal Medicine, Division of Gastroenterology and Hepatology, Mayo Clinic College of Medicine, Rochester, Minnesota
Vascular Diseases of the Gastrointestinal Tract

Frederick G. Hayden, MD
Stuart S. Richardson Professor of Clinical Virology and Professor of Medicine, University of Virginia School of Medicine; Staff Physician, University of Virginia Health System, Charlottesville, Virginia
Influenza

Douglas C. Heimburger, MD, MS
Professor of Medicine, Associate Director for Education and Training, Vanderbilt University School of Medicine, Vanderbilt Institute for Global Health, Nashville, Tennessee
Nutrition's Interface with Health and Disease

Erik L. Hewlett, MD
Professor of Medicine and of Microbiology, Immunology, and Cancer Biology, University of Virginia School of Medicine, University of Virginia Health System, Charlottesville, Virginia
Whooping Cough and Other Bordetella Infections

Richard J. Hift, PhD, MMed
School of Clinical Medicine, University of KwaZulu-Natal, Durban, South Africa
The Porphyrias

David R. Hill, MD, DTM&H
Professor of Medical Sciences, Director of Global Public Health, Frank H. Netter MD School of Medicine at Quinnipiac University, Hamden, Connecticut
Giardiasis

Nicholas S. Hill, MD
Professor of Medicine, Tufts University School of Medicine; Chief, Division of Pulmonary, Critical Care, and Sleep Medicine, Tufts Medical Center, Boston, Massachusetts
Respiratory Monitoring in Critical Care

L. David Hillis, MD
Professor and Chair, Department of Medicine, University of Texas Health Science Center at San Antonio, San Antonio, Texas
Acute Coronary Syndrome: Unstable Angina and Non-ST Elevation Myocardial Infarction

Jack Hirsh, CM, MD, DSc
Professor Emeritus, McMaster University, Hamilton, Ontario, Canada
Antithrombotic Therapy

Steven M. Holland, MD
Chief, Laboratory of Clinical Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland
The Nontuberculous Mycobacteria

Steven M. Hollenberg, MD
Professor of Medicine, Cooper Medical School of Rowan University; Director, Coronary Care Unit, Cooper University Hospital, Camden, New Jersey
Cardiogenic Shock

Edward W. Hook III, MD
Professor and Director, Division of Infectious Diseases, University of Alabama at Birmingham, Birmingham, Alabama
Granuloma Inguinale (Donovanosis); Syphilis; Nonsyphilitic Treponematoses

David J. Hunter, MBBS, MPH, ScD
Vincent L. Gregory Professor of Cancer Prevention, Harvard School of Public Health; Professor of Medicine, Harvard Medical School, Brigham and Women's Hospital, Boston, Massachusetts
The Epidemiology of Cancer

Khalid Hussain, MBChB, MD, MSc
Developmental Endocrinology Research Group, Clinical and Molecular Genetics Unit, Institute of Child Health, University College London, Department of Paediatric Endocrinology, Great Ormond Street Hospital for Children, London, United Kingdom
Hypoglycemia/Pancreatic Islet Cell Disorders

Steven E. Hyman, MD
Director, Stanley Center for Psychiatric Research, Broad Institute, Distinguished Service Professor of Stem Cell and Regenerative Biology, Harvard University, Cambridge, Massachusetts
Biology of Addiction

Michael C. Iannuzzi, MD, MBA
Chairman, Department of Internal Medicine, State University of New York Upstate Medical University, Syracuse, New York
Sarcoidosis

Robert D. Inman, MD
Professor of Medicine and Immunology, University of Toronto; Staff Rheumatologist, University Health Network, Toronto, Ontario, Canada
The Spondyloarthropathies

Sharon K. Inouye, MD, MPH
Professor of Medicine, Harvard Medical School; Director, Aging Brain Center, Institute for Aging Research, Hebrew SeniorLife, Boston, Massachusetts
Neuropsychiatric Aspects of Aging; Delirium or Acute Mental Status Change in the Older Patient

Geoffrey K. Isbister, MD, BSc
Associate Professor, Clinical Toxicologist, Calvary Mater Newcastle, Callaghan, Senior Research Academic, School of Medicine and Public Health, University of Newcastle, New South Wales, Australia
Envenomation

Michael G. Ison, MD, MS
Associate Professor in Medicine-Infectious Diseases and Surgery-Organ Transplantation, Northwestern University Feinberg School of Medicine, Chicago, Illinois
Adenovirus Diseases

Elias Jabbour, MD
Associate Professor, Department of Leukemia, Division of Medicine, The University of Texas MD Anderson Cancer Center, Houston, Texas
The Chronic Leukemias

Michael R. Jaff, DO
Professor of Medicine, Harvard Medical School, Chair, Institute for Heart, Vascular, and Stroke Care, Massachusetts General Hospital, Boston, Massachusetts
Other Peripheral Arterial Diseases

Joanna C. Jen, MD, PhD
Professor of Neurology, University of California Los Angeles School of Medicine, Los Angeles, California
Neuro-Ophthalmology; Smell and Taste; Hearing and Equilibrium

Dennis M. Jensen, MD
Professor of Medicine, David Geffen School of Medicine at University of California Los Angeles; Staff Physician, Medicine-GI, VA Greater Los Angeles Healthcare System; Key Investigator, Director, Human Studies Core & GI Hemostasis Research Unit, CURE Digestive Diseases Research Center, Los Angeles, California
Gastrointestinal Hemorrhage

Michael D. Jensen, MD
Professor of Medicine, Endocrine Research Unit, Director, Obesity Treatment Research Program, Mayo Clinic, Rochester, Minnesota
Obesity

Robert T. Jensen, MD
Chief, Cell Biology Section, Digestive Disease Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Clinical Center, Bethesda, Maryland
Pancreatic Neuroendocrine Tumors

Stuart Johnson, MD
Professor of Medicine, Loyola University Chicago Stritch School of Medicine; Associate Chief of Staff for Research, Edward Hines, Jr. VA Hospital, Hines, Illinois
Clostridial Infections

Richard C. Jordan, DDS, PhD
Professor of Oral Pathology, Pathology and Radiation Oncology, University of California San Francisco, San Francisco, California
Diseases of the Mouth and Salivary Glands

Ralph F. Józefowicz, MD
Professor, Neurology and Medicine, University of Rochester, Rochester, New York
Approach to the Patient with Neurologic Disease

Stephen G. Kaler, MD
Senior Investigator and Head, Section on Translational Neuroscience, Molecular Medicine Program, Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, Maryland
Wilson Disease

Moses R. Kamya, MB ChB, MMed, MPH, PhD
Chairman, Department of Medicine, Makerere University College of Health Sciences, Kampala, Uganda
Malaria

Louise W. Kao, MD
Associate Professor of Emergency Medicine, Department of Emergency Medicine, Indiana University School of Medicine, Indianapolis, Indiana
Chronic Poisoning: Trace Metals and Others

Steven A. Kaplan, MD
E. Darracott Vaughan, Jr. Professor of Urology, Chief, Institute for Bladder and Prostate Health, Weill Cornell Medical College; Director, Iris Cantor Men's Health Center, NewYork–Presbyterian Hospital, New York, New York
Benign Prostatic Hyperplasia and Prostatitis

Daniel L. Kastner, MD, PhD
Scientific Director, National Human Genome Research Institute, National Institutes of Health, Bethesda, Maryland
The Systemic Autoinflammatory Diseases

Sekar Kathiresan, MD
Associate Professor in Medicine, Harvard Medical School; Director, Preventive Cardiology, Massachusetts General Hospital, Boston, Massachusetts
The Inherited Basis of Common Diseases

David A. Katzka, MD
Professor of and Consultant in Medicine, Gastroenterology, Mayo Clinic, Rochester, Minnesota
Diseases of the Esophagus

Debra K. Katzman, MD
Professor of Pediatrics, Senior Associate Scientist, The Research Institute, The Hospital for Sick Children and University of Toronto, Toronto, Ontario, Canada
Adolescent Medicine

Carol A. Kauffman, MD
Professor of Internal Medicine, University of Michigan Medical School; Chief, Infectious Diseases Section, Veterans Affairs Ann Arbor Healthcare System, Ann Arbor, Michigan
Histoplasmosis; Blastomycosis; Paracoccidioidomycosis; Cryptococcosis; Sporotrichosis; Candidiasis

Kenneth Kaushansky, MD
Senior Vice President for Health Sciences, Dean, School of Medicine, Stony Brook University, Stony Brook, New York
Hematopoiesis and Hematopoietic Growth Factors

Keith S. Kaye, MD, MPH
Professor of Medicine, Division of Infectious Diseases, Wayne State University School of Medicine, Detroit, Michigan
Diseases Caused by Acinetobacter and Stenotrophomonas Species

Armand Keating, MD
Professor of Medicine, Director, Division of Hematology, Epstein Chair in Cell Therapy and Transplantation, Professor, Institute of Biomaterials and Biomedical Engineering, University of Toronto, Toronto, Ontario, Canada
Hematopoietic Stem Cell Transplantation

Robin K. Kelley, MD
Assistant Professor of Medicine, University of California San Francisco, Helen Diller Family Comprehensive Cancer Center, San Francisco, California
Liver and Biliary Tract Cancers

Morton Kern, MD
Chief of Medicine, VA Long Beach Health Care System School of Medicine; Professor of Medicine, Associate Chief, Cardiology, University of California–Irvine, Irvine, California
Catheterization and Angiography

Gerald T. Keusch, MD
Professor of Medicine and International Health and Public Health, Boston University School of Medicine, Boston, Massachusetts
Shigellosis

Fadlo R. Khuri, MD
Professor and Chair, Hematology and Medical Oncology, Deputy Director, Winship Cancer Institute, Emory University, Atlanta, Georgia
Lung Cancer and Other Pulmonary Neoplasms

David H. Kim, MD
Vice Chair of Education, Professor of Radiology, Section of Abdominal Imaging, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin
Diagnostic Imaging Procedures in Gastroenterology

Matthew Kim, MD
Instructor of Medicine, Harvard Medical School; Associate Physician, Brigham and Women's Hospital, Boston, Massachusetts
Thyroid

Louis V. Kirchhoff, MD, MPH
Professor, Departments of Internal Medicine (Infectious Diseases) and Epidemiology, University of Iowa Health Care; Staff Physician, Medical Service, Department of Veterans Affairs Medical Center, Iowa City, Iowa
Chagas Disease

David S. Knopman, MD
Professor of Neurology, Mayo Clinic College of Medicine, Rochester, Minnesota
Regional Cerebral Dysfunction: Higher Mental Function; Alzheimer Disease and Other Dementias

Tamsin A. Knox, MD, MPH
Associate Professor of Medicine, Nutrition/Infection Unit, Tufts University School of Medicine, Boston, Massachusetts
Gastrointestinal Manifestions of HIV and AIDS

D.P. Kontoyiannis, MD, ScD
Professor, Department of Infectious Diseases, Infection Control and Employee Health, The University of Texas MD Anderson Cancer Center, Houston, Texas
Mucormycosis; Mycetoma

Barbara S. Koppel, MD
Professor of Clinical Neurology, New York Medical College, Chief of Neurology, Metropolitan Hospital Center, New York City Health and Hospital Corporation, New York, New York
Nutritional and Alcohol-Related Neurologic Disorders

Kevin M. Korenblat, MD
Associate Professor of Medicine, Department of Medicine, Washington University School of Medicine, St. Louis, Missouri
Approach to the Patient with Jaundice or Abnormal Liver Tests

Bruce R. Korf, MD, PhD
Wayne H. and Sara Crews Finley Chair in Medical Genetics, Professor and Chair, Department of Genetics, University of Alabama at Birmingham, Birmingham, Alabama
Principles of Genetics

Neil J. Korman, MD, PhD
Professor, Dermatology, Case Western Reserve University School of Medicine, University Hospitals Case Medical Center, Cleveland, Ohio
Macular, Papular, Vesiculobullous, and Pustular Diseases

Mark G. Kortepeter, MD, MPH
Associate Dean for Research, Associate Professor of Preventive Medicine and Medicine, Consultant to the Army Surgeon General for Biodefense; Office of the Dean, Edward Hébert School of Medicine, Uniformed Services University of the Health Sciences, Bethesda, Maryland
Bioterrorism

Joseph A. Kovacs, MD
Senior Investigator and Head, AIDS Section, Critical Care Medicine Department, National Institutes of Health, Bethesda, Maryland
Pneumocystis Pneumonia

Thomas O. Kovacs, MD
Professor of Medicine, Division of Digestive Diseases, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, California
Gastrointestinal Hemorrhage

Monica Kraft, MD
Professor of Medicine, Duke University School of Medicine; Chief, Division of Pulmonary, Allergy, and Critical Care Medicine, Duke University Medical Center, Durham, North Carolina
Approach to the Patient with Respiratory Disease

Christopher M. Kramer, MD
Ruth C. Heede Professor of Cardiology, Professor of Radiology, Director, Cardiovascular Imaging Center, University of Virginia Health System, Charlottesville, Virginia
Noninvasive Cardiac Imaging

Donna M. Krasnewich, MD, PhD
Program Director, National Institute of General Medical Sciences, National Institutes of Health, Bethesda, Maryland
The Lysosomal Storage Diseases

Peter J. Krause, MD
Senior Research Scientist in Epidemiology, Medicine, and Pediatrics, Yale School of Public Health and Yale School of Medicine, New Haven, Connecticut
Babesiosis and Other Protozoan Diseases

John F. Kuemmerle, MD
Chair, Division of Gastroenterology, Hepatology, and Nutrition, Professor of Medicine, and Physiology and Biophysics, Center for Digestive Health, Virginia Commonwealth University, Richmond, Virginia
Inflammatory and Anatomic Diseases of the Intestine, Peritoneum, Mesentery, and Omentum

Ernst J. Kuipers, MD, PhD
Professor of Medicine, Department of Gastroenterology and Hepatology, Chief Executive Officer, Erasmus MC University Medical Center, Rotterdam, The Netherlands
Acid Peptic Disease

Paul W. Ladenson, MD
Professor of Medicine, Pathology, Oncology, and Radiology and Radiological Sciences, John Eager Howard Professor of Endocrinology and Metabolism, University Distinguished Service Professor, The Johns Hopkins University School of Medicine; Physician and Division Director, The Johns Hopkins Hospital, Baltimore, Maryland
Thyroid

Daniel Laheru, MD
Ian T. MacMillan Professorship in Clinical Pancreatic Research, Medical Oncology, Johns Hopkins University School of Medicine, Baltimore, Maryland
Pancreatic Cancer

Donald W. Landry, MD, PhD
Samuel Bard Professor of Medicine, Chair, Department of Medicine, Physician-in-Chief, NewYork-Presbyterian Hospital/Columbia University Medical Center, New York, New York
Approach to the Patient with Renal Disease

Anthony E. Lang, MD
Director, Division of Neurology, Jack Clark Chair for Research in Parkinson's Disease, University of Toronto; Director, Morton and Gloria Shulman Movement Disorders Clinic and the Edmond J. Safra Program in Parkinson's Disease and the Lily Safra Chair in Movement Disorders, Toronto Western Hospital, Toronto, Ontario, Canada
Parkinsonism; Other Movement Disorders

Richard A. Lange, MD, MBA
President and Dean, Paul L. Foster School of Medicine, Texas Tech University Health Sciences Center El Paso, El Paso, Texas
Acute Coronary Syndrome: Unstable Angina and Non-ST Elevation Myocardial Infarction

Frank A. Lederle, MD
Core Investigator, Center for Chronic Disease Outcomes Research, Minneapolis VA Medical Center; Professor of Medicine, University of Minnesota School of Medicine, Minneapolis, Minnesota
Diseases of the Aorta

Thomas H. Lee, MD, MSc
Senior Physician, Department of Medicine, Brigham and Women's Hospital; Chief Medical Officer, Press Ganey, Boston, Massachusetts
Using Data for Clinical Decisions

William M. Lee, MD
Professor of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, Texas
Toxin- and Drug-Induced Liver Disease

James E. Leggett, MD
Associate Professor, Department of Medicine, Oregon Health and Science University; Infectious Diseases, Department of Medical Education, Providence Portland Medical Center, Portland, Oregon
Approach to Fever or Suspected Infection in the Normal Host

Stuart Levin, MD
Professor of Medicine, Emeritus Chairman, Department of Medicine, Rush University Medical Center, Chicago, Illinois
Zoonoses

Stephanie M. Levine, MD
Professor of Medicine, Division of Pulmonary Diseases and Critical Care Medicine, The University of Texas Health Science Center San Antonio, South Texas Veterans Health Care System, San Antonio, Texas
Alveolar Filling Disorders

Gary R. Lichtenstein, MD
Professor of Medicine, Perelman School of Medicine at the University of Pennsylvania, Director, Center for Inflammatory Bowel Disease, University of Pennsylvania, Philadelphia, Pennsylvania
Inflammatory Bowel Disease

Henry W. Lim, MD
Chairman and C.S. Livingood Chair, Department of Dermatology, Henry Ford Hospital; Senior Vice President for Academic Affairs, Henry Ford Health System, Detroit, Michigan
Eczemas, Photodermatoses, Papulosquamous (Including Fungal) Diseases, and Figurate Erythemas

Aldo A.M. Lima, MD, PhD
Professor of Medicine and Pharmacology, School of Medicine, Federal University of Ceará, Fortaleza, Ceará, Brazil
Cryptosporidiosis; Amebiasis

Geoffrey S.F. Ling, MD, PhD
Professor of Neurology, Uniformed Services University of the Health Sciences, Bethesda, Maryland
Traumatic Brain Injury and Spinal Cord Injury

William C. Little, MD
Patrick Lehan Professor of Cardiovascular Medicine, Chair, Department of Medicine, University of Mississippi Medical Center, Jackson, Mississippi
Pericardial Diseases

Donald M. Lloyd-Jones, MD, ScM
Senior Associate Dean, Chair, Department of Preventive Medicine, Eileen M. Foell Professor of Preventive Medicine and Medicine, Northwestern University Feinberg School of Medicine, Chicago, Illinois
Epidemiology of Cardiovascular Disease

Bennett Lorber, MD
Thomas M. Durant Professor of Medicine and Professor of Microbiology and Immunology, Temple University School of Medicine, Philadelphia, Pennsylvania
Listeriosis

Donald E. Low, MD[†]
Nonpneumococcal Streptococcal Infections, Rheumatic Fever

Daniel R. Lucey, MD, MPH
Adjunct Professor, Microbiology and Immunology, Georgetown University Medical Center, Washington, D.C.
Anthrax

James R. Lupski, MD, PhD
Cullen Professor of Molecular and Human Genetics, Professor of Pediatrics, Baylor College of Medicine and Texas Children's Hospital, Houston, Texas
Gene, Genomic, and Chromosomal Disorders

Jeffrey M. Lyness, MD
Senior Associate Dean for Academic Affairs, Professor of Psychiatry and Neurology, University of Rochester School of Medicine and Dentistry, Rochester, New York
Psychiatric Disorders in Medical Practice

Bruce W. Lytle, MD
Chair, Heart and Vascular Institute, Professor of Surgery, Thoracic and Cardiovascular Surgery, Cleveland Clinic, Cleveland, Ohio
Interventional and Surgical Treatment of Coronary Artery Disease

[†]Deceased.

C. Ronald MacKenzie, MD
Assistant Attending Physician, Department of Medicine-Rheumatology, C. Ronald MacKenzie Chair in Ethics and Medicine, Hospital for Special Surgery, Associate Professor of Clinical Medicine and Medical Ethics, Weill Cornell Medical College of Cornell University, New York, New York
Surgical Treatment of Joint Disease

Harriet L. MacMillan, MD, MSc
Professor, Departments of Psychiatry and Behavioural Neurosciences, and Pediatrics, Chedoke Health Chair in Child Psychiatry, Offord Centre for Child Studies, McMaster University, Hamilton, Ontario, Canada
Intimate Partner Violence

Robert D. Madoff, MD
Professor of Surgery, Stanley M. Goldberg, MD, Chair, Colon and Rectal Surgery, University of Minnesota, Minneapolis, Minnesota
Diseases of the Rectum and Anus

Frank Maldarelli, MD, PhD
Head, Clinical Retrovirology Section, HIV Drug Resistance Program, National Cancer Institute, National Institutes of Health, Bethesda, Maryland
Biology of Human Immunodeficiency Viruses

Atul Malhotra, MD
Chief of Pulmonary and Critical Care, Kenneth M. Moser Professor of Medicine, Director of Sleep Medicine, University of California San Diego, La Jolla, California
Disorders of Ventilatory Control

Mark J. Manary, MD
Helene B. Roberson Professor of Pediatrics, Washington University School of Medicine; Attending Physician, St. Louis Children's Hospital, St. Louis, Missouri; Adjunct Professor, Children's Nutrition Research Center, Baylor College of Medicine, Houston, Texas; Senior Lecturer in Community Health, University of Malawi College of Medicine, Blantyre, Malawi
Protein-Energy Malnutrition

Donna Mancini, MD
Professor of Medicine, Department of Medicine, Division of Cardiology, Columbia University College of Physicians and Surgeons, Center for Advanced Cardiac Care, Columbia University Medical Center, New York, New York
Cardiac Transplantation

Lionel A. Mandell, MD
Professor of Medicine, Faculty of Health Sciences, McMaster University, Hamilton, Ontario, Canada
Streptococcus Pneumoniae *Infections*

Peter Manu, MD
Professor of Medicine and Psychiatry, Hofstra North Shore–LIJ School of Medicine at Hofstra University, Hempstead, New York; Adjunct Professor of Clinical Medicine, Psychiatry and Behavioral Sciences, Albert Einstein College of Medicine, Bronx, New York; Director of Medical Services, Zucker Hillside Hospital, Glen Oaks, New York
Medical Consultation in Psychiatry

Ariane Marelli, MD, MPH
Professor of Medicine, McGill University, Director, McGill Adult Unit for Congenital Heart Disease, Associate Director, Academic Affairs and Research, Cardiology, McGill University Health Centre, Montreal, Québec, Canada
Congenital Heart Disease in Adults

Xavier Mariette, MD, PhD
Professor, Rheumatology, Université Paris-Sud, AP-HP, Le Kremlin Bicêtre, France
Sjögren Syndrome

Andrew R. Marks, MD
Wu Professor and Chair, Department of Physiology and Cellular Biophysics, Founding Director, Helen and Clyde Wu Center for Molecular Cardiology, Columbia University College of Physicians and Surgeons, New York, New York
Cardiac Function and Circulatory Control

Kieren A. Marr, MD
Professor of Medicine and Oncology, The Johns Hopkins University, Director, Transplant and Oncology Infectious Diseases, Baltimore, Maryland
Approach to Fever and Suspected Infection in the Compromised Host

Thomas J. Marrie, MD
Dean, Faculty of Medicine, Dalhousie University; Professor of Medicine, Capital District Health Authority, Halifax, Nova Scotia, Canada
Legionella Infections

Paul Martin, MD
Professor of Medicine and Chief, Division of Hepatology, Miller School of Medicine, University of Miami, Miami, Florida
Approach to the Patient with Liver Disease

Joel B. Mason, MD
Professor of Medicine and Nutrition, Tufts University; Staff Physician, Divisions of Gastroenterology and Clinical Nutrition, Tufts Medical Center, Boston, Massachusetts
Vitamins, Trace Minerals, and Other Micronutrients

Henry Masur, MD
Chief, Critical Care Medicine Department, Clinical Center, National Institutes of Health, Bethesda, Maryland
Infectious and Metabolic Complications of HIV and AIDS

Eric L. Matteson, MD, MPH
Professor of Medicine, Mayo Clinic College of Medicine, Consultant, Divisions of Rheumatology and Epidemiology, Mayo Clinic, Rochester, Minnesota
Infections of Bursae, Joints, and Bones

Michael A. Matthay, MD
Professor, Departments of Medicine and Anesthesia, University of California San Francisco, San Francisco, California
Acute Respiratory Failure

Toby A. Maurer, MD
Professor of Dermatology, University of California San Francisco; Chief of Dermatology, San Francisco General Hospital, San Francisco, California
Skin Manifestations in Patients with Human Immunodeficiency Virus Infection

Emeran A. Mayer, MD, PhD
Professor of Medicine, Physiology, and Psychiatry, Division of Digestive Diseases, Department of Medicine, University of California Los Angeles, Los Angeles, California
Functional Gastrointestinal Disorders: Irritable Bowel Syndrome, Dyspepsia, Chest Pain of Presumed Esophageal Origin, and Heartburn

Stephan A. Mayer, MD
Director, Institute for Critical Care Medicine, Icahn School of Medicine at Mount Sinai, New York, New York
Hemorrhagic Cerebrovascular Disease

Stephen A. McClave, MD
Professor of Medicine, Director of Clinical Nutrition, University of Louisville School of Medicine, Louisville, Kentucky
Enteral Nutrition

F. Dennis McCool, MD
Professor of Medicine, The Warren Alpert Medical School of Brown University; Medical Director of Sleep Center, Memorial Hospital of Rhode Island, Pawtucket, Rhode Island
Diseases of the Diaphragm, Chest Wall, Pleura, and Mediastinum

Charles E. McCulloch, PhD
Professor of Biostatistics, Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, California
Statistical Interpretation of Data

William J. McKenna, MD
Professor of Cardiology, Institute of Cardiovascular Science, University College London, London, United Kingdom
Diseases of the Myocardium and Endocardium

Vallerie McLaughlin, MD
Kim A. Eagle, MD, Endowed Professor of Cardiovascular Medicine, Director, Pulmonary Hypertension Program, University of Michigan, Ann Arbor, Michigan
Pulmonary Hypertension

John J.V. McMurray, MB, MD
Professor of Cardiology, Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, Scotland, United Kingdom
Heart Failure: Management and Prognosis

Kenneth R. McQuaid, MD
Professor of Clinical Medicine, Marvin H. Sleisenger Endowed Chair, Vice Chairman, University of California San Francisco; Chief, Medical Services and Gastroenterology, San Francisco VA Medical Center, San Francisco, California
Approach to the Patient with Gastrointestinal Disease

Marc Michel, MD
Professor of Internal Medicine, Head of the Unit of Internal Medicine at Henri Mondor University Hospital, National Referral Center for Adult's Immune Cytopenias, Creteil, France
Autoimmune and Intravascular Hemolytic Anemias

Jonathan W. Mink, MD, PhD
Frederick A. Horner, MD Endowed Professor in Pediatric Neurology, Professor of Neurology, Neurobiology & Anatomy, Brain & Cognitive Sciences, and Pediatrics, Chief, Division of Child Neurology, Vice Chair, Department of Neurology, University of Rochester, Rochester, New York
Congenital, Developmental, and Neurocutaneous Disorders

William E. Mitch, MD
Gordon A. Cain Chair in Nephrology, Director of Nephrology, Baylor College of Medicine, Houston, Texas
Chronic Kidney Disease

Mark E. Molitch, MD
Martha Leland Sherwin Professor of Endocrinology, Division of Endocrinology, Metabolism, and Molecular Medicine, Northwestern University Feinberg School of Medicine, Chicago, Illinois
Neuroendocrinology and the Neuroendocrine System; Anterior Pituitary

Bruce A. Molitoris, MD
Professor of Medicine, and Cellular and Integrative Physiology Director, Indiana Center for Biological Microscopy, Indiana University, Indianapolis, Indiana
Acute Kidney Injury

Jose G. Montoya, MD
Professor of Medicine, Division of Infectious Disease and Geographic Medicine, Stanford University School of Medicine, Stanford, California; Director, Palo Alto Medical Foundation Toxoplasma Serology Laboratory, National Reference Center for the Study and Diagnosis of Toxoplasmosis, Palo Alto, California
Toxoplasmosis

Alison Morris, MD, MS
Associate Professor of Medicine, Clinical Translational Science, and Immunology, Division of Pulmonary, Allergy, and Critical Care Medicine, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania
Pulmonary Manifestations of Human Immunodeficiency Virus and Acquired Immunodeficiency Syndrome

Ernest Moy, MD, MPH
Medical Officer, Center for Quality Improvement and Patient Safety Agency for Healthcare Research and Quality, Rockville, Maryland
Measuring Health and Health Care

Atis Muehlenbachs, MD, PhD
Infectious Diseases Pathology Branch, Centers for Disease Control and Prevention, Atlanta, Georgia
Leptospirosis

Andrew H. Murr, MD
Professor and Chairman, Roger Boles, MD Endowed Chair in Otolaryngology Education, Department of Otolaryngology-Head and Neck Surgery, University of California San Francisco School of Medicine, San Francisco, California
Approach to the Patient with Nose, Sinus, and Ear Disorders

Daniel M. Musher, MD
Professor of Medicine, Molecular Virology, and Microbiology, Distinguished Service Professor, Baylor College of Medicine, Infectious Disease Section, Michael E. DeBakey Veterans Affairs Medical Center, Houston, Texas
Overview of Pneumonia

Robert J. Myerburg, MD
Professor of Medicine and Physiology, Division of Cardiology, Department of Medicine, American Heart Association Chair in Cardiovascular Research, University of Miami Miller School of Medicine, Miami, Florida
Approach to Cardiac Arrest and Life-Threatening Arrhythmias

Sandesh C.S. Nagamani, MD
Assistant Professor, Department of Molecular and Human Genetics, Director, Clinic for Metabolic and Genetic Disorders of Bone, Baylor College of Medicine and Texas Children's Hospital, Houston, Texas
Gene, Genomic, and Chromosomal Disorders

Stanley J. Naides, MD
Medical Director and Interim Scientific Director, Immunology, Quest Diagnostics Nichols Institute, San Juan Capistrano, California
Arboviruses Causing Fever and Rash Syndromes

Yoshifumi Naka, MD, PhD
Professor of Surgery, Department of Surgery, Columbia University College of Physicians and Surgeons, New York, New York
Cardiac Transplantation

Theodore E. Nash, MD
Principal Investigator, Clinical Parasitology Section, Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland
Giardiasis

Avindra Nath, MD
Chief, Section of Infections of the Nervous System, National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, Maryland
Cytomegalovirus, Epstein-Barr Virus, and Slow Virus Infections of the Central Nervous System; Neurologic Complications of Human Immunodeficiency Virus Infection; Meningitis: Bacterial, Viral, and Other; Brain Abscess and Parameningeal Infections

Eric G. Neilson, MD
Vice President for Medical Affairs and Lewis Landsberg Dean, Northwestern University Feinberg School of Medicine, Northwestern Memorial Hospital, Chicago, Illinois
Tubulointerstitial Nephritis

Lawrence S. Neinstein, MD
Professor of Pediatrics and Medicine, Keck School of Medicine of USC; Executive Director, Engemann Student Health Center, Division Head of College Health, Assistant Provost, Student Health and Wellness, University of Southern California, Los Angeles, California
Adolescent Medicine

Lewis S. Nelson, MD
Professor of Emergency Medicine, Director, Fellowship in Medical Toxicology, New York University School of Medicine; Attending Physician, New York University Langone Medical Center and Bellevue Hospital Center, New York, New York
Acute Poisoning

Eric J. Nestler, MD, PhD
Nash Family Professor and Chair, Department of Neuroscience, Director, The Friedman Brain Institute, Icahn School of Medicine at Mount Sinai, New York, New York
Biology of Addiction

Anne B. Newman, MD, MPH
Professor of Epidemiology, The University of Pittsburgh Graduate School of Public Health; Chair, Department of Epidemiology, Director, University of Pittsburgh Center for Aging and Population Health, Pittsburgh, Pennsylvania
Epidemiology of Aging: Implications of the Aging of Society

Thomas B. Newman, MD, MPH
Professor, Epidemiology & Biostatistics and Pediatrics, University of California San Francisco, San Francisco, California
Statistical Interpretation of Data

William L. Nichols, MD
Associate Professor, Medicine and Laboratory Medicine, Mayo Clinic College of Medicine; Staff Physician, Special Coagulation Laboratory, Comprehensive Hemophilia Center, and Coagulation Clinic, Mayo Clinic, Rochester, Minnesota
Von Willebrand Disease and Hemorrhagic Abnormalities of Platelet and Vascular Function

Lindsay E. Nicolle, MD
Professor of Internal Medicine and Medical Microbiology, University of Manitoba, Health Sciences Centre, Winnipeg, Manitoba, Canada
Approach to the Patient with Urinary Tract Infection

Lynnette K. Nieman, MD
Senior Investigator, Program on Reproductive and Adult Endocrinology, Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, Maryland
Approach to the Patient with Endocrine Disease; Adrenal Cortex; Polyglandular Disorders

Dennis E. Niewoehner, MD
Professor of Medicine, University of Minnesota; Staff Physician, Minneapolis Veterans Affairs Health Care System, Minneapolis, Minnesota
Chronic Obstructive Pulmonary Disease

S. Ragnar Norrby, MD, PhD
Director General, Swedish Institute for Infectious Disease Control, Solna, Sweden
Approach to the Patient with Urinary Tract Infection

Susan O'Brien, MD
Professor, Department of Leukemia, Division of Medicine, The University of Texas MD Anderson Cancer Center, Houston, Texas
The Chronic Leukemias

Christopher M. O'Connor, MD
Professor of Medicine and Chief, Division of Cardiology, Director, Duke Heart Center, Durham, North Carolina
Heart Failure: Pathophysiology and Diagnosis

Francis G. O'Connor, MD, MPH
Professor and Chair, Military and Emergency Medicine, Medical Director, Uniformed Services University Consortium for Health and Military Performance, Bethesda, Maryland
Disorders Due to Heat and Cold; Rhabdomyolysis

Patrick G. O'Connor, MD, MPH
Professor and Chief, General Internal Medicine, Yale University School of Medicine, New Haven, Connecticut
Alcohol Abuse and Dependence

James R. O'Dell, MD
Bruce Professor and Vice Chair of Internal Medicine, Chief, Division of Rheumatology, University of Nebraska Medical Center and Omaha VA Nebraska–Western Iowa Health Care System, Omaha, Nebraska
Rheumatoid Arthritis

Anne E. O'Donnell, MD
Professor of Medicine, Chief, Division of Pulmonary, Critical Care, and Sleep Medicine, Georgetown University Medical Center, Washington, D.C.
Bronchiectasis, Atelectasis, Cysts, and Localized Lung Disorders

Jae K. Oh, MD
Professor of Medicine, Director, Echocardiography Core Laboratory and Pericardial Clinic, Division of Cardiovascular Diseases, Co-Director, Integrated Cardiac Imaging, Division of Cardiovascular Diseases, Mayo Clinic, Rochester, Minnesota
Pericardial Diseases

Jeffrey E. Olgin, MD
Gallo-Chatterjee Distinguished Professor of Medicine, Chief, Division of Cardiology, Co-Director, Heart and Vascular Center, University of California San Francisco, San Francisco, California
Approach to the Patient with Suspected Arrhythmia

Walter A. Orenstein, MD
Professor of Medicine, Pediatrics, and Global Health, Emory University School of Medicine, Atlanta, Georgia
Immunization

Douglas R. Osmon, MD, MPH
Professor of Medicine, Mayo Clinic College of Medicine; Consultant, Division of Infectious Diseases, Mayo Clinic, Rochester, Minnesota
Infections of Bursae, Joints, and Bones

Catherine M. Otto, MD
J. Ward Kennedy-Hamilton Endowed Chair in Cardiology, Professor of Medicine, University of Washington School of Medicine; Director, Heart Valve Clinic, University of Washington Medical Center, Seattle, Washington
Echocardiography

Mark Papania, MD, MPH
Medical Epidemiologist, Division of Viral Diseases, Measles, Mumps, Rubella, and Herpes Virus Laboratory Branch, Centers for Disease Control and Prevention, Atlanta, Georgia
Measles

Peter G. Pappas, MD
Professor of Medicine, University of Alabama at Birmingham, Birmingham, Alabama
Dematiaceous Fungal Infections

Pankaj Jay Pasricha, MD
Director, The Johns Hopkins Center for Neurogastroenterology; Professor of Medicine and Neurosciences, The Johns Hopkins School of Medicine; Professor of Innovation Management, Johns Hopkins Carey Business School, Baltimore, Maryland
Gastrointestinal Endoscopy

David L. Paterson, MD
Professor of Medicine, University of Queensland Centre for Clinical Research, Royal Brisbane and Women's Hospital Campus, Brisbane, Queensland, Australia
Infections Due to Other Members of the Enterobacteriaceae, Including Management of Multidrug Resistant Strains

Carlo Patrono, MD
Professor and Chair of Pharmacology, Department of Pharmacology, Catholic University School of Medicine, Rome, Italy
Prostaglandin, Aspirin, and Related Compounds

Jean-Michel Pawlotsky, MD, PhD
Professor of Medicine, The University of Paris-Est; Director, National Reference Center for Viral Hepatitis B, C, and Delta and Department of Virology, Henri Mondor University Hospital; Director, Department of Molecular Virology and Immunology, Institut Mondor de Recherche Biomédicale, Créteil, France
Acute Viral Hepatitis; Chronic Viral and Autoimmune Hepatitis

Richard D. Pearson, MD
Professor of Medicine and Pathology, University of Virginia School of Medicine and University of Virginia Health System, Charlottesville, Virginia
Antiparasitic Therapy

Trish M. Perl, MD, MSc
Professor of Medicine and Pathology, The Johns Hopkins School of Medicine; Professor of Epidemiology, Johns Hopkins Bloomberg School of Public Health; Infectious Diseases Specialist and Senior Epidemiologist, The Johns Hopkins Hospital and Health System, Baltimore, Maryland
Enterococcal Infections

Adam Perlman, MD, MPH
Associate Professor, Department of Medicine, Duke University Medical Center; Executive Director, Duke Integrative Medicine, Duke University Health System, Durham, North Carolina
Complementary and Alternative Medicine

William A. Petri, Jr., MD, PhD
Wade Hampton Frost Professor, Departments of Medicine, Pathology, Microbiology, Immunology, and Cancer Biology, School of Medicine, University of Virginia; Chief, Division of Infectious Diseases and International Health, University of Virginia Hospitals, Charlottesville, Virginia
Relapsing Fever and Other Borrelia Infections; African Sleeping Sickness; Amebiasis

Marc A. Pfeffer, MD, PhD
Dzau Professor of Medicine, Harvard Medical School; Senior Physician, Cardiovascular Division, Brigham and Women's Hospital, Boston, Massachusetts
Heart Failure: Management and Prognosis

Perry J. Pickhardt, MD
Professor of Radiology and Chief, Gastrointestinal Imaging, Section of Abdominal Imaging, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin
Diagnostic Imaging Procedures in Gastroenterology

David S. Pisetsky, MD, PhD
Chief of Rheumatology, Medical Research Service, Durham VA Medical Center; Professor of Medicine and Immunology, Department of Medicine, Duke University Medical Center, Durham, North Carolina
Laboratory Testing in the Rheumatic Diseases

Marshall R. Posner, MD
Professor of Medicine, Director of Head and Neck Medical Oncology, Director of the Office of Cancer Clinical Trials, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, New York
Head and Neck Cancer

Frank Powell, PhD
Professor of Medicine, Chief of Physiology, University of California San Diego, La Jolla, California
Disorders of Ventilatory Control

Reed E. Pyeritz, MD, PhD
William Smilow Professor of Medicine and Genetics and Vice Chair for Academic Affairs, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, Pennsylvania
Inherited Diseases of Connective Tissue

Thomas C. Quinn, MD, MSc
Associate Director for International Research, Head, Section of International HIV/AIDS Research, Division of Intramural Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health; Professor of Medicine, Pathology, International Health, Molecular Microbiology and Immunology, and Epidemiology, The Johns Hopkins Medical Institutions, Baltimore, Maryland
Epidemiology and Diagnosis of Human Immunodeficiency Virus Infection and Acquired Immunodeficiency Syndrome

Jai Radhakrishnan, MD, MS
Professor of Medicine, Division of Nephrology, Department of Medicine, Columbia University Medical Center; Associate Division Chief for Clinical Affairs, Division of Nephrology, New York-Presbyterian Hospital, New York, New York
Glomerular Disorders and Nephrotic Syndromes

Petros I. Rafailidis, MD, PhD, MSc
Senior Researcher, Alfa Institute of Biomedical Sciences, Attending Physician, Department of Medicine and Hematology, Athens Medical Center, Athens Medical Group, Athens, Greece
Pseudomonas and Related Gram-Negative Bacillary Infections

Ganesh Raghu, MD
Adjunct Professor of Medicine and Laboratory Medicine, University of Washington, Director, CENTER for Interstitial Lung Diseases at the University of Washington; Co-Director, Scleroderma Clinic, University of Washington Medical Center, Seattle, Washington
Interstitial Lung Disease

Margaret Ragni, MD, MPH
Professor of Medicine and Clinical Translational Science, Department of Hematology/Oncology, University of Pittsburgh Medical Center; Director, Hemophilia Center of Western Pennsylvania, Pittsburgh, Pennsylvania
Hemorrhagic Disorders: Coagulation Factor Deficiencies

Srinivasa N. Raja, MD
Professor of Anesthesiology and Neurology, Director, Division of Pain Medicine, The Johns Hopkins University School of Medicine, Baltimore, Maryland
Pain

S. Vincent Rajkumar, MD
Professor of Medicine, Division of Hematology, Mayo Clinic, Rochester, Minnesota
Plasma Cell Disorders

Stuart H. Ralston, MB ChB, MD
Professor of Rheumatology, Institute of Genetics and Molecular Medicine, Western General Hospital, The University of Edinburgh, Edinburgh, United Kingdom
Paget Disease of Bone

Didier Raoult, MD, PhD
Professor, Aix Marseille Université, Faculté de Médecine; Chief, Hôpital de la Timone, Fédération de Microbiologie Clinique, Marseille, France
Bartonella Infections; Rickettsial Infections

Robert W. Rebar, MD
Professor, Department of Obstetrics and Gynecology, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, Michigan
Ovaries and Development; Reproductive Endocrinology and Infertility

Annette C. Reboli, MD
Founding Vice Dean, Professor of Medicine, Cooper Medical School of Rowan University, Cooper University Healthcare, Department of Medicine, Division of Infectious Diseases, Camden, New Jersey
Erysipelothrix Infections

K. Rajender Reddy, MD
Professor of Medicine, Professor of Medicine in Surgery, Perelman School of Medicine at the University of Pennsylvania; Director of Hepatology, Director, Viral Hepatitis Center, Hospital of the University of Pennsylvania, Philadelphia, Pennsylvania
Bacterial, Parasitic, Fungal, and Granulomatous Liver Diseases

Donald A. Redelmeier, MD
Professor of Medicine, University of Toronto; Senior Scientist and Staff Physician, Sunnybrook Health Sciences Centre, Toronto, Ontario, Canada
Postoperative Care and Complications

Susan E. Reef, MD
Centers for Disease Control and Prevention, Atlanta, Georgia
Rubella (German Measles)

Neil M. Resnick, MD
Thomas P. Detre Endowed Chair in Gerontology and Geriatric Medicine, Professor of Medicine and Division Chief, Geriatrics, Associate Director, University of Pittsburgh Institute on Aging, University of Pittsburgh; Chief, Division of Geriatric Medicine and Gerontology, University of Pittsburgh Medical Center, Pittsburgh, Pennsylvania
Incontinence

David B. Reuben, MD
Director, Multicampus Program in Geriatric Medicine and Gerontology; Chief, Division of Geriatrics, Archstone Professor of Medicine, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, California
Geriatric Assessment

Emanuel P. Rivers, MD, MPH
Professor and Vice Chairman of Emergency Medicine, Wayne State University; Senior Staff Attending, Critical Care and Emergency Medicine, Henry Ford Hospital, Detroit, Michigan
Approach to the Patient with Shock

Joseph G. Rogers, MD
Professor of Medicine, Senior Vice Chief for Clinical Affairs, Division of Cardiology, Durham, North Carolina
Heart Failure: Pathophysiology and Diagnosis

Jean-Marc Rolain, PharmD, PhD
Professor, Institut Hospitalo-Universitaire Méditerranée-Infection, Aix-Marseille Université, Marseille, France
Bartonella Infections

José R. Romero, MD
Professor of Pediatrics, University of Arkansas for Medical Sciences, Horace C. Cabe Professor of Infectious Diseases; Director, Section of Pediatric Infectious Diseases, Arkansas Children's Hospital, Little Rock, Arkansas
Enteroviruses

Karen Rosene-Montella, MD
Professor and Vice Chair of Medicine, Director of Obstetric Medicine, The Warren Alpert Medical School of Brown University; Senior Vice President, Women's Services and Clinical Integration, Lifespan Health System, Providence, Rhode Island
Common Medical Problems in Pregnancy

Philip J. Rosenthal, MD
Professor, Department of Medicine, University of California San Francisco, San Francisco, California
Malaria

Marc E. Rothenberg, MD, PhD
Director, Division of Allergy and Immunology, Director, Cincinnati Center for Eosinophilic Disorders; Professor of Pediatrics, Cincinnati Children's Hospital Medical Center, University of Cincinnati College of Medicine, Cincinnati, Ohio
Eosinophilic Syndromes

James A. Russell, MD
Professor of Medicine, University of British Columbia; Associate Director, Intensive Care Unit, St. Paul's Hospital, Vancouver, British Columbia, Canada
Shock Syndromes Related to Sepsis

Anil K. Rustgi, MD
T. Grier Miller Professor of Medicine and Genetics, Chief of Gastroenterology, American Cancer Society; Professor, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, Pennsylvania
Neoplasms of the Esophagus and Stomach

Daniel E. Rusyniak, MD
Professor of Emergency Medicine, Adjunct Professor of Neurology and Pharmacology and Toxicology, Department of Emergency Medicine, Indiana University School of Medicine, Indianapolis, Indiana
Chronic Poisoning: Trace Metals and Others

Robert A. Salata, MD
Professor and Executive Vice Chair, Department of Medicine, Chief, Division of Infectious Diseases and HIV Medicine, Case Western Reserve University, University Hospitals Case Medical Center, Cleveland, Ohio
Brucellosis

Jane E. Salmon, MD
Collette Kean Research Chair, Hospital for Special Surgery, Professor of Medicine, Weill Cornell Medical College, New York, New York
Mechanisms of Immune-Mediated Tissue Injury

Edsel Maurice T. Salvana, MD, DTM&H
Associate Professor of Medicine, Section of Infectious Diseases, Department of Medicine, Philippine General Hospital; Director, Institute of Molecular Biology and Biotechnology, National Institutes of Health, University of the Philippines Manila, Manila, Philippines
Brucellosis

Renato M. Santos, MD
Associate Professor, Cardiology, Wake Forest School of Medicine, Winston-Salem, North Carolina
Vascular Disorders of the Kidney

Michael N. Sawka, PhD
Professor, School of Applied Physiology, Georgia Institute of Technology, Atlanta, Georgia
Disorders Due to Heat and Cold

Paul D. Scanlon, MD
Professor of Medicine, Division of Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, Minnesota
Respiratory Function: Mechanisms and Testing

Carla Scanzello, MD, PhD
Assistant Professor of Medicine, Division of Rheumatology, Perelman School of Medicine at the University of Pennsylvania and Translational Musculoskeletal Research Center, Philadelphia Veterans Affairs Medical Center, Philadelphia, Pennsylvania
Osteoarthritis

Andrew I. Schafer, MD
Professor of Medicine, Director, Richard T. Silver Center for Myeloproliferative Neoplasms, Weill Cornell Medical College, New York, New York
Approach to Medicine, the Patient, and the Medical Profession: Medicine as a Learned and Humane Profession; Approach to the Patient with Bleeding and Thrombosis; Hemorrhagic Disorders: Disseminated Intravascular Coagulation, Liver Failure, and Vitamin K Deficiency; Thrombotic Disorders: Hypercoagulable States

William Schaffner, MD
Professor and Chair, Department of Preventive Medicine, Department of Health Policy; Professor of Medicine (Infectious Diseases), Vanderbilt University School of Medicine, Nashville, Tennessee
Tularemia and Other Francisella Infections

W. Michael Scheld, MD
Bayer-Gerald L. Mandell Professor of Infectious Diseases, Professor of Medicine, Clinical Professor of Neurosurgery, Director, Pfizer Initiative in International Health, University of Virginia Health System, Charlottesville, Virginia
Introduction to Microbial Disease: Host-Pathogen Interactions

Manuel Schiff, MD
Professor, Université Paris 7 Denis Diderot, Sorbonne Paris Cité, Head of Metabolic Unit/Reference Center for Inborn Errors of Metabolism, Robert Debré University Hospital, APHP, Paris, France
Homocystinuria and Hyperhomocysteinemia

Michael L. Schilsky, MD
Associate Professor, Medicine and Surgery, Yale University School of Medicine, New Haven, Connecticut
Wilson Disease

Robert T. Schooley, MD
Professor and Head, Division of Infectious Diseases, Executive Vice Chair for Academic Affairs, Department of Medicine, University of California San Diego, La Jolla, California
Epstein-Barr Virus Infection

David L. Schriger, MD, MPH
Professor, Department of Emergency Medicine, University of California Los Angeles, Los Angeles, California
Approach to the Patient with Abnormal Vital Signs

Steven A. Schroeder, MD
Distinguished Professor of Health and Healthcare and of Medicine, University of California San Francisco, San Francisco, California
Socioeconomic Issues in Medicine

Lynn M. Schuchter, MD
Professor of Medicine, University of Pennsylvania; Chief, Hematology/Oncology Division, Program Leader, Melanoma and Cutaneous Malignancies Program, Abramson Cancer Center, Hospital of the University of Pennsylvania, Philadelphia, Pennsylvania
Melanoma and Nonmelanoma Skin Cancers

Sam Schulman, MD, PhD
Professor, Division of Hematology and Thromboembolism, Director of Clinical Thromboembolism Program, Department of Medicine, McMaster University, Hamilton, Ontario, Canada
Antithrombotic Therapy

Lawrence B. Schwartz, MD, PhD
Charles and Evelyn Thomas Professor of Medicine, Internal Medicine, Virginia Commonwealth University, Richmond, Virginia
Systemic Anaphylaxis, Food Allergy, and Insect Sting Allergy

Carlos Seas, MD
Associate Professor of Medicine, Vice Director, Alexander von Humboldt Tropical Medicine Institute, Universidad Peruana Cayetano Heredia; Attending Physician, Department of Infectious, Tropical, and Dermatologic Diseases, National Hospital Cayetano Heredia, Lima, Peru
Cholera and Other Vibrio Infections

Steven A. Seifert, MD
Professor of Emergency Medicine, University of New Mexico School of Medicine, Medical Director, New Mexico Poison and Drug Information Center, University of New Mexico Health Sciences Center, Albuquerque, New Mexico
Envenomation

Julian L. Seifter, MD
Associate Professor of Medicine, Harvard Medical School; Senior Physician, Brigham and Women's Hospital, Boston, Massachusetts
Potassium Disorders; Acid-Base Disorders

Duygu Selcen, MD
Associate Professor of Neurology and Pediatrics, Department of Neurology, Mayo Clinic, Rochester, Minnesota
Muscle Diseases

Clay F. Semenkovich, MD
Herbert S. Gasser Professor and Chief, Division of Endocrinology, Metabolism and Lipid Research, Washington University School of Medicine, St. Louis, Missouri
Disorders of Lipid Metabolism

Carol E. Semrad, MD
Professor of Medicine, The University of Chicago Medicine, GI Section, Chicago, Illinois
Approach to the Patient with Diarrhea and Malabsorption

Harry Shamoon, MD
Professor of Medicine and Associate Dean for Clinical and Translational Research, Albert Einstein College of Medicine; Director, Harold and Muriel Block Institute for Clinical and Translational Research at Einstein and Montefiore, Bronx, New York
Diabetes Mellitus

James C. Shaw, MD
Associate Professor, Department of Medicine, University of Toronto; Head, Division of Dermatology, Department of Medicine, Women's College Hospital, Toronto, Ontario, Canada
Examination of the Skin and an Approach to Diagnosing Skin Diseases

Pamela J. Shaw, DBE, MBBS, MD
Professor of Neurology, University of Sheffield, Consultant Neurologist, Royal Hallamshire Hospital, Sheffield, United Kingdom
Amyotrophic Lateral Sclerosis and Other Motor Neuron Diseases

Robert L. Sheridan, MD
Associate Professor of Surgery, Burn Service Medical Director, Boston Shriners Hospital for Children, Massachusetts General Hospital, Division of Burns, Harvard Medical School, Boston, Massachusetts
Medical Aspects of Injuries and Burns

Stuart Sherman, MD
Professor of Medicine and Radiology, Director of ERCP, Indiana University School of Medicine, Indianapolis, Indiana
Diseases of the Gallbladder and Bile Ducts

Michael E. Shy, MD
Professor of Neurology, Pediatrics, and Physiology, University of Iowa, Iowa City, Iowa
Peripheral Neuropathies

Ellen Sidransky, MD
Chief, Section on Molecular Neurogenetics, Medical Genetics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, Maryland
The Lysosomal Storage Diseases

Richard M. Siegel, MD, PhD
Clinical Director, National Institute of Arthritis, Musculoskeletal, and Skin Diseases, National Institutes of Health, Bethesda, Maryland
The Systemic Autoinflammatory Diseases

Robert F. Siliciano, MD, PhD
Professor, The Johns Hopkins University School of Medicine, Howard Hughes Medical Institute, Baltimore, Maryland
Immunopathogenesis of Human Immunodeficiency Virus Infection

Michael S. Simberkoff, MD
Chief of Staff, VA New York Harbor Healthcare System; Professor of Medicine, NYU School of Medicine, New York, New York
Haemophilus and Moraxella Infections

David L. Simel, MD, MHS
Professor of Medicine, Duke University; Chief, Medical Service, Durham Veterans Affairs Medical Center, Durham, North Carolina
Approach to the Patient: History and Physical Examination

Kamaljit Singh, MD
Associate Professor of Medicine, Attending Physician, Infectious Diseases, Rush University Medical Center, Chicago, Illinois
Zoonoses

Karl Skorecki, MD
Annie Chutick Professor in Medicine, Rappaport Faculty of Medicine and Research Institute, Technion–Israel Institute of Technology; Director, Medical and Research Development, Rambam Health Care Campus, Haifa, Israel
Gene and Cell Therapy; Disorders of Sodium and Water Homeostasis

Itzchak Slotki, MD
Associate Professor of Medicine, Hebrew University, Hadassah Medical School; Director, Division of Adult Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel
Disorders of Sodium and Water Homeostasis

Arthur S. Slutsky, MD
Professor of Medicine, Surgery, and Biomedical Engineering, University of Toronto; Vice President (Research), St. Michael's Hospital, Keenan Research Centre, Li Ka Shing Knowledge Institute, Toronto, Ontario, Canada
Acute Respiratory Failure; Mechanical Ventilation

Eric J. Small, MD
Professor of Medicine and Urology, Deputy Director and Director of Clinical Sciences, Helen Diller Family Comprehensive Cancer Center; Chief, Division of Hematology and Oncology, University of California San Francisco School of Medicine, San Francisco, California
Prostate Cancer

Gerald W. Smetana, MD
Professor of Medicine, Harvard Medical School; Division of General Medicine and Primary Care, Beth Israel Deaconess Medical Center, Boston, Massachusetts
Principles of Medical Consultation

Frederick S. Southwick, MD
Professor of Medicine, Division of Infectious Diseases, University of Florida and VF Health, Gainesville, Florida
Nocardiosis

Allen M. Spiegel, MD
Dean, Albert Einstein College of Medicine, Bronx, New York
Principles of Endocrinology; Polyglandular Disorders

Robert F. Spiera, MD
Professor of Clinical Medicine, Weill Cornell Medical College; Director, Scleroderma, Vasculitis, and Myositis Center, The Hospital for Special Surgery, New York, New York
Polymyalgia Rheumatica and Temporal Arteritis

Stanley M. Spinola, MD
Professor and Chair, Department of Microbiology and Immunology, Professor of Medicine, Microbiology and Immunology, and Pathology and Laboratory Medicine, Indiana University School of Medicine, Indianapolis, Indiana
Chancroid

David Spriggs, MD
Head, Division of Solid Tumor Oncology, Department of Medicine, Memorial Sloan Kettering Cancer Center; Professor of Medicine, Department of Medicine, Weill Cornell Medical College, New York, New York
Gynecologic Cancers

Paweł Stankiewicz, MD, PhD
Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, Texas
Gene, Genomic, and Chromosomal Disorders

Paul Stark, MD
Professor Emeritus, University of California San Diego; Chief of Cardiothoracic Radiology, VA San Diego Healthcare System, San Diego, California
Imaging in Pulmonary Disease

David P. Steensma, MD
Professor of Medicine, Harvard Medical School, Adult Leukemia Program, Dana-Farber Cancer Institute, Boston, Massachusetts
Myelodysplastic Syndrome

Martin H. Steinberg, MD
Professor of Medicine, Pediatrics, and Pathology and Laboratory Medicine, Boston University School of Medicine; Director, Center of Excellence in Sickle Cell Disease, Boston Medical Center, Boston, Massachusetts
Sickle Cell Disease and Other Hemoglobinopathies

Theodore S. Steiner, MD
Associate Professor, University of British Columbia; Associate Head, Division of Infectious Diseases, Vancouver General Hospital, Vancouver, British Columbia, Canada
Escherichia Coli *Enteric Infections*

David S. Stephens, MD
Stephen W. Schwarzmann Distinguished Professor of Medicine, Emory University School of Medicine and Woodruff Health Sciences Center, Atlanta, Georgia
Neisseria Meningitidis *Infections*

David A. Stevens, MD
Professor of Medicine, Stanford University Medical School; President, Principal Investigator, Infectious Diseases Research Laboratory, California Institute for Medical Research, San Jose and Stanford, California
Systemic Antifungal Agents

James K. Stoller, MD, MS
Chairman, Education Institute, Jean Wall Bennett Professor of Medicine, Cleveland Clinic Lerner College of Medicine; Staff, Respiratory Institute, Cleveland Clinic, Cleveland, Ohio
Respiratory Monitoring in Critical Care

John H. Stone, MD, MPH
Professor of Medicine, Director, Clinical Rheumatology, Harvard Medical School, Massachusetts General Hospital, Boston, Massachusetts
The Systemic Vasculitides

Richard M. Stone, MD
Professor of Medicine, Harvard Medical School, Clinical Director, Adult Leukemia Program, Dana-Farber Cancer Institute, Boston, Massachusetts
Myelodysplastic Syndrome

Raymond A. Strikas, MD, MPH
Education Team Lead, Immunization Services Division, National Center for Immunization and Respiratory Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia
Immunization

Edwin P. Su, MD
Associate Professor of Clinical Orthopaedics, Orthopaedic Surgery, Weill Cornell University Medical College; Associate Attending Orthopaedic Surgeon, Adult Reconstruction and Joint Replacement, Hospital for Special Surgery, New York, New York
Surgical Treatment of Joint Disease

Roland W. Sutter, MD, MPH&TM
Coordinator, Research, Policy and Product Development, Polio Operations and Research Department, World Health Organization, Geneva, Switzerland
Diphtheria and Other Corynebacteria Infections

Ronald S. Swerdloff, MD
Professor of Medicine, David Geffen School of Medicine at University of California Los Angeles; Chief, Division of Endocrinology, Department of Medicine, Harbor-UCLA Medical Center, Torrance, California
The Testis and Male Hypogonadism, Infertility, and Sexual Dysfunction

Heidi Swygard, MD, MPH
Associate Professor of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina
Approach to the Patient with a Sexually Transmitted Infection

Megan Sykes, MD
Michael J. Friedlander Professor of Medicine, Director, Columbia Center for Translational Immunology, Columbia University Medical Center, New York, New York
Transplantation Immunology

Marian Tanofsky-Kraff, PhD
Associate Professor, Department of Medical and Clinical Psychology, Uniformed Services University of Health Sciences, Bethesda, Maryland
Eating Disorders

Susan M. Tarlo, MBBS
Professor of Medicine, Department of Medicine and Dalla Lana School of Public Health, University of Toronto, Respiratory Physician, University Health Network, Toronto Western Hospital and St. Michael's Hospital, Toronto, Ontario, Canada
Occupational Lung Disease

Victoria M. Taylor, MD, MPH
Professor of Medicine, University of Washington, Fred Hutchinson Cancer Research Center, Seattle, Washington
Cultural Context of Medicine

Ayalew Tefferi, MD
Professor of Medicine, Department of Hematology, Mayo Clinic, Rochester, Minnesota
Polycythemia Vera, Essential Thrombocythemia, and Primary Myelofibrosis

Paul S. Teirstein, MD
Chief of Cardiology, Department of Medicine, Scripps Clinic, La Jolla, California
Interventional and Surgical Treatment of Coronary Artery Disease

Sam R. Telford III, ScD
Professor, Tufts University Cummings School of Veterinary Medicine, North Grafton, Massachusetts
Babesiosis and Other Protozoan Diseases

Rajesh V. Thakker, MD
May Professor of Medicine, University of Oxford; Radcliffe Department of Clinical Medicine, OCDEM, Churchill Hospital, Headington, Oxford, United Kingdom
The Parathyroid Glands, Hypercalcemia, and Hypocalcemia

Antonella Tosti, MD
Professor of Clinical Dermatology, Department of Dermatology and Cutaneous Surgery, University of Miami, Miami, Florida
Diseases of Hair and Nails

Indi Trehan, MD, MPH, DTM&H
Assistant Professor of Pediatrics, Washington University School of Medicine; Attending Physician, St. Louis Children's Hospital, Barnes-Jewish Hospital, St. Louis, Missouri; Visiting Honorary Lecturer in Paediatrics and Child Health, University of Malawi College of Medicine; Consultant Paediatrician, Queen Elizabeth Central Hospital, Blantyre, Malawi
Protein-Energy Malnutrition

Ronald B. Turner, MD
Professor of Pediatrics, University of Virginia School of Medicine, Charlottesville, Virginia
The Common Cold

Thomas S. Uldrick, MD
Staff Clinician, HIV and AIDS Malignancy Branch, National Cancer Institute, Bethesda, Maryland
Hematology and Oncology in Patients with Human Immunodeficiency Virus Infection

Anthony M. Valeri, MD
Professor of Medicine, Columbia University Medical Center; Director, Hemodialysis, Medical Director, Kidney and Pancreas Transplantation, New York-Presbyterian Hospital (CUMC); Director, Hemodialysis, Columbia University Dialysis Center, New York, New York
Treatment of Irreversible Renal Failure

John Varga, MD
John and Nancy Hughes Professor of Medicine, Northwestern University Feinberg School of Medicine, Chicago, Illinois
Systemic Sclerosis (Scleroderma)

Bradley V. Vaughn, MD
Professor of Neurology, Department of Neurology, University of North Carolina, Chapel Hill, North Carolina
Disorders of Sleep

Alan P. Venook, MD
Professor of Medicine, University of California San Francisco, Helen Diller Family Comprehensive Cancer Center, San Francisco, California
Liver and Biliary Tract Cancers

Joseph G. Verbalis, MD
Professor of Medicine, Georgetown University; Chief, Endocrinology and Metabolism, Georgetown University Hospital, Washington, D.C.
Posterior Pituitary

Ronald G. Victor, MD
Professor of Medicine, Burns and Allen Chair in Cardiology Research, Director, Hypertension Center, Associate Director, The Heart Institute, Cedars-Sinai Medical Center, Los Angeles, California
Arterial Hypertension

Angela Vincent, MBBS
Professor of Neuroimmunology, University of Oxford; Honorary Consultant in Immunology, Oxford University Hospital Trust, Oxford, United Kingdom
Disorders of Neuromuscular Transmission

Robert M. Wachter, MD
Professor and Associate Chairman, Department of Medicine, University of California San Francisco, San Francisco, California
Quality of Care and Patient Safety

Edward H. Wagner, MD, MPH
Director Emeritus, MacColl Center for Health Care Innovation, Group Health Research Institute, Seattle, Washington
Comprehensive Chronic Disease Management

Edward E. Walsh, MD
Professor of Medicine, University of Rochester School of Medicine and Dentistry; Head, Infectious Diseases, Rochester General Hospital, Rochester, New York
Respiratory Syncytial Virus

Thomas J. Walsh, MD
Director, Transplantation-Oncology Infectious Diseases Program, Chief, Infectious Diseases Translational Research Laboratory, Professor of Medicine, Pediatrics, and Microbiology and Immunology, Weill Cornell Medical Center; Henry Schueler Foundation Scholar, Sharp Family Foundation Scholar in Pediatric Infectious Diseases, Adjunct Professor of Pathology, The Johns Hopkins University School of Medicine; Adjunct Professor of Medicine, The University of Maryland School of Medicine, Baltimore, Maryland
Aspergillosis

Jeremy D. Walston, MD
Raymond and Anna Lublin Professor of Geriatric Medicine and Gerontology, The Johns Hopkins University School of Medicine, Baltimore, Maryland
Common Clinical Sequelae of Aging

Christina Wang, MD
Professor of Medicine, David Geffen School of Medicine at University of California Los Angeles; Associate Director, UCLA Clinical and Translational Research Institute, Harbor-UCLA Medical Center, Torrance, California
The Testis and Male Hypogonadism, Infertility, and Sexual Dysfunction

Christine Wanke, MD
Professor of Medicine and Public Health, Director, Division of Nutrition and Infection, Associate Chair, Department of Public Health, Tufts University School of Medicine, Boston, Massachusetts
Gastrointestinal Manifestions of HIV and AIDS

Stephen I. Wasserman, MD
Professor of Medicine, University of California San Diego, La Jolla, California
Approach to the Patient with Allergic or Immunologic Disease

Thomas J. Weber, MD
Associate Professor, Medicine/Endocrinology, Duke University, Durham, North Carolina
Approach to the Patient with Metabolic Bone Disease; Osteoporosis

Heiner Wedemeyer, MD
Professor, Department of Gastroenterology, Hepatology, and Endocrinology, Hannover Medical School, Hannover, Germany
Acute Viral Hepatitis

Geoffrey A. Weinberg, MD
Professor of Pediatrics, University of Rochester School of Medicine and Dentistry; Director, Pediatric HIV Program, Golisano Children's Hospital at University of Rochester Medical Center, Rochester, New York
Parainfluenza Viral Disease

David A. Weinstein, MD, MMSc
Professor of Pediatric Endocrinology, Director, Glycogen Storage Disease Program, Division of Pediatric Endocrinology, University of Florida College of Medicine, Gainesville, Florida
Glycogen Storage Diseases

Robert S. Weinstein, MD
Professor of Medicine, Department of Medicine, University of Arkansas for Medical Sciences; Staff Endocrinologist, Department of Medicine, Central Arkansas Veterans Health Care System, Little Rock, Arkansas
Osteomalacia and Rickets

Roger D. Weiss, MD
Professor of Psychiatry, Harvard Medical School, Boston, Massachusetts; Chief, Division of Alcohol and Drug Abuse, McLean Hospital, Belmont, Massachusetts
Drug Abuse and Dependence

Martin Weisse, MD
Chair, Pediatrics, Tripler Army Medical Center, Honolulu, Hawaii; Professor, Pediatrics, Uniformed Services University of the Health Sciences, Bethesda, Maryland
Measles

Jeffrey I. Weitz, MD
Professor of Medicine and Biochemistry, McMaster University; Executive Director, Thrombosis and Atherosclerosis Research Institute, Hamilton, Ontario, Canada
Pulmonary Embolism

Samuel A. Wells, Jr., MD
Medical Oncology Branch, National Cancer Institute, National Institutes of Health, Bethesda, Maryland
Medullary Thyroid Carcinoma

Richard P. Wenzel, MD, MSc
Professor and Former Chairman, Internal Medicine, Virginia Commonwealth University, Richmond, Virginia
Acute Bronchitis and Tracheitis

Victoria P. Werth, MD
Professor of Dermatology and Medicine, Hospital of the University of Pennsylvania and Philadelphia Veterans Administration Medical Center; Chief, Dermatology Division, Philadelphia Veterans Administration Medical Center, Philadelphia, Pennsylvania
Principles of Therapy of Skin Diseases

Sterling G. West, MD, MACP
Professor of Medicine, University of Colorado School of Medicine; Associate Division Head for Clinical and Educational Affairs, University of Colorado Division of Rheumatology, Aurora, Colorado
Systemic Diseases in Which Arthritis Is a Feature

A. Clinton White, Jr., MD
Paul R. Stalnaker Distinguished Professor and Director, Infectious Disease Division, Department of Internal Medicine, University of Texas Medical Branch, Galveston, Texas
Cestodes

Christopher J. White, MD
Professor of Medicine, Ochsner Clinical School, University of Queensland School of Medicine; System Chairman of Cardiovascular Diseases, Ochsner Medical Center, New Orleans, Louisiana
Atherosclerotic Peripheral Arterial Disease; Electrophysiologic Interventional Procedures and Surgery

Perrin C. White, MD
Professor of Pediatrics, The Audry Newman Rapoport Distinguished Chair in Pediatric Endocrinology, University of Texas Southwestern Medical Center, Chief of Endocrinology, Children's Medical Center Dallas, Dallas, Texas
Disorders of Sexual Development

Richard J. Whitley, MD
Distinguished Professor of Pediatrics, Loeb Eminent Scholar Chair in Pediatrics, Professor of Pediatrics, Microbiology, Medicine, and Neurosurgery, The University of Alabama at Birmingham, Birmingham, Alabama
Herpes Simplex Virus Infections

Michael P. Whyte, MD
Professor of Medicine, Pediatrics, and Genetics, Division of Bone and Mineral Diseases, Washington University School of Medicine; Medical-Scientific Director, Center for Metabolic Bone Disease and Molecular Research, Shriners Hospital for Children, St. Louis, Missouri
Osteonecrosis, Osteosclerosis/Hyperostosis, and Other Disorders of Bone

Samuel Wiebe, MD, MSc
Professor of Clinical Neurosciences, University of Calgary; Co-Director, Calgary Epilepsy Program, Alberta Health Services, Foothills Medical Centre, Calgary, Alberta, Canada
The Epilepsies

Jeanine P. Wiener-Kronish, MD
Henry Isaiah Dorr Professor of Research and Teaching in Anaesthesia and Anesthestist-in-Chief, Department of Anesthesia, Critical Care and Pain Medicine, Massachusetts General Hospital/Harvard Medical School, Boston, Massachusetts
Overview of Anesthesia

Eelco F.M. Wijdicks, MD, PhD
Professor of Neurology, Division of Critical Care Neurology, Department of Neurology, Mayo Clinic, Rochester, Minnesota
Coma, Vegetative State, and Brain Death

David J. Wilber, MD
George M. Eisenberg Professor of Medicine, Loyola Stritch School of Medicine; Director, Division of Cardiology, Director, Clinical Electrophysiology, Loyola University Medical Center, Maywood, Illinois
Electrophysiologic Interventional Procedures and Surgery

Beverly Winikoff, MD, MPH
President, Gynuity Health Projects; Professor of Clinical Population and Family Health, Mailman School of Public Health, Columbia University, New York, New York
Contraception

Gary P. Wormser, MD
Professor of Medicine and Chief, Division of Infectious Diseases, Department of Medicine, New York Medical College, Valhalla, New York
Lyme Disease

Myron Yanoff, MD
Professor and Chair, Ophthalmology, Drexel University College of Medicine, Philadelphia, Pennsylvania
Diseases of the Visual System

Robert Yarchoan, MD
Branch Chief, HIV and AIDS Malignancy Branch, National Cancer Institute, Bethesda, Maryland
Hematology and Oncology in Patients with Human Immunodeficiency Virus Infection

Neal S. Young, MD
Chief, Hematology Branch, NHLBI and Director, Trans-NIH Center for Human Immunology, Autoimmunity, and Inflammation, National Institutes of Health, Bethesda, Maryland
Parvovirus

William F. Young, Jr., MD, MSc
Professor of Medicine, Mayo Clinic College of Medicine; Chair, Division of Endocrinology, Diabetes, Metabolism, and Nutrition, Mayo Clinic, Rochester, Minnesota
Adrenal Medulla, Catecholamines, and Pheochromocytoma

Alan S.L. Yu, MB, BChir
Harry Statland and Solon Summerfield Professor of Medicine, Director, Division of Nephrology and Hypertension and the Kidney Institute, University of Kansas Medical Center, Kansas City, Kansas
Disorders of Magnesium and Phosphorus

Sherif R. Zaki, MD, PhD
Chief, Infectious Diseases Pathology Branch, Centers for Disease Control and Prevention, Atlanta, Georgia
Leptospirosis

Mark L. Zeidel, MD
Herman L. Blumgart Professor of Medicine, Harvard Medical School; Physician-in-Chief and Chairman, Department of Medicine, Beth Israel Deaconess Medical Center, Boston, Massachusetts
Obstructive Uropathy

Thomas R. Ziegler, MD
Professor, Department of Medicine, Division of Endocrinology, Metabolism, and Lipids, Emory University School of Medicine, Atlanta, Georgia
Malnutrition, Nutritional Assessment, and Nutritional Support in Adult Hospitalized Patients

Peter Zimetbaum, MD
Associate Professor of Medicine, Harvard Medical School; Director of Clinical Cardiology, Beth Israel Deaconess Medical Center, Boston, Massachusetts
Cardiac Arrhythmias with Supraventricular Origin

APPROACH TO MEDICINE, THE PATIENT, AND THE MEDICAL PROFESSION: MEDICINE AS A LEARNED AND HUMANE PROFESSION

LEE GOLDMAN AND ANDREW I. SCHAFER

APPROACH TO MEDICINE

Medicine is a profession that incorporates science and the scientific method with the art of being a physician. The art of tending to the sick is as old as humanity itself. Even in modern times, the art of caring and comforting, guided by millennia of common sense as well as a more recent, systematic approach to medical ethics (Chapter 2), remains the cornerstone of medicine. Without these humanistic qualities, the application of the modern science of medicine is suboptimal, ineffective, or even detrimental.

The caregivers of ancient times and premodern cultures tried a variety of interventions to help the afflicted. Some of their potions contained what are now known to be active ingredients that form the basis for proven medications (Chapter 29). Others (Chapter 39) have persisted into the present era despite a lack of convincing evidence. Modern medicine should not dismiss the possibility that these unproven approaches may be helpful; instead, it should adopt a guiding principle that all interventions, whether traditional or newly developed, can be tested vigorously, with the expectation that any beneficial effects can be explored further to determine their scientific basis.

When compared with its long and generally distinguished history of caring and comforting, the scientific basis of medicine is remarkably recent. Other than an understanding of human anatomy and the later description, albeit widely contested at this time, of the normal physiology of the circulatory system, almost all of modern medicine is based on discoveries made within the past 150 years. Until the late 19th century, the paucity of medical knowledge was perhaps exemplified best by hospitals and hospital care. Although hospitals provided caring that all but well-to-do people might not be able to obtain elsewhere, there is little if any evidence that hospitals improved health outcomes. The term *hospitalism* referred not to expertise in hospital care but rather to the aggregate of iatrogenic afflictions that were induced by the hospital stay itself.

The essential humanistic qualities of caring and comforting can achieve full benefit only if they are coupled with an understanding of how medical science can and should be applied to patients with known or suspected diseases. Without this knowledge, comforting may be inappropriate or misleading, and caring may be ineffective or counterproductive if it inhibits a sick person from obtaining appropriate, scientific medical care. *Goldman-Cecil Medicine* focuses on the discipline of *internal medicine,* from which neurology and dermatology, which are also covered in substantial detail in this text, are relatively recent evolutionary branches. The term *internal medicine,* which is often misunderstood by the lay public, was developed in 19th-century Germany. *Inneren medizin* was to be distinguished from clinical medicine because it emphasized the physiology and chemistry of disease, not just the patterns or progression of clinical manifestations. *Goldman-Cecil Medicine* follows this tradition by showing how pathophysiologic abnormalities cause symptoms and signs and by emphasizing how therapies can modify the underlying pathophysiology and improve the patient's well-being.

Modern medicine has moved rapidly past organ physiology to an increasingly detailed understanding of cellular, subcellular, and genetic mechanisms. For example, the understanding of microbial pathogenesis and many inflammatory diseases (Chapter 256) is now guided by a detailed understanding of the human immune system and its response to foreign antigens (Chapters 45 to 49). Advances in our understanding of the human microbiome raise the possibility that our complex interactions with microbes, which outnumber our cells by a factor of 10, will help explain conditions ranging from inflammatory bowel disease (Chapter 141) to obesity (Chapter 220).[1]

Health, disease, and an individual's interaction with the environment are also substantially determined by genetics. In addition to many conditions that may be determined by a single gene (Chapter 41), medical science increasingly understands the complex interactions that underlie multigenic traits (Chapter 42). The decoding of the human genome holds the promise that personalized health care increasingly can be targeted according to an individual's genetic profile, in terms of screening and presymptomatic disease management, as well as in terms of specific medications and their adjusted dosing schedules.[2]

Although gene therapy has been approved for only one disease, lipoprotein lipase deficiency (Chapter 206), and only in Europe, it has shown promise in other conditions, such as Leber congenital amaurosis (Chapter 423). Cell therapy is now beginning to provide vehicles for the delivery of genes, gene products, and vaccines. It has also opened the way for "regenerative medicine" by facilitating the regeneration of injured or diseased organs and tissues. Such advances and others, such as nanomedicine, have already led to targeted and personalized therapies for a variety of cancers.[3] Knowledge of the structure and physical forms of proteins helps explain abnormalities as diverse as sickle cell anemia (Chapter 163) and prion-related diseases (Chapter 415). Proteomics, which is the normal and abnormal protein expression of genes, also holds extraordinary promise for developing drug targets for more specific and effective therapies.

Concurrent with these advances in fundamental human biology has been a dramatic shift in methods for evaluating the application of scientific advances to the individual patient and to populations. The randomized controlled trial, sometimes with thousands of patients at multiple institutions, has replaced anecdote as the preferred method for measuring the benefits and optimal uses of diagnostic and therapeutic interventions (Chapter 10). As studies progress from those that show biologic effect, to those that elucidate dosing schedules and toxicity, and finally to those that assess true clinical benefit, the metrics of measuring outcome has also improved from subjective impressions of physicians or patients to reliable and valid measures of morbidity, quality of life, functional status, and other patient-oriented outcomes (Chapter 11). These marked improvements in the scientific methodology of clinical investigation have expedited extraordinary changes in clinical practice, such as recanalization therapy for acute myocardial infarction (Chapter 73), and have shown that reliance on intermediate outcomes, such as a reduction in asymptomatic ventricular arrhythmias with certain drugs, may unexpectedly increase rather than decrease mortality. Just as physicians in the 21st century must understand advances in fundamental biology, similar understanding of the fundamentals of clinical study design as it applies to diagnostic and therapeutic interventions is needed. An understanding of human genetics will also help stratify and refine the approach to clinical trials by helping researchers select fewer patients with a more homogeneous disease pattern to study the efficacy of an intervention.

This explosion in medical knowledge has led to increasing specialization and subspecialization, defined initially by organ system and more recently by locus of principal activity (inpatient vs. outpatient), reliance on manual skills (proceduralist vs. nonproceduralist), or participation in research. Nevertheless, it is becoming increasingly clear that the same fundamental molecular and genetic mechanisms are broadly applicable across all organ systems and that the scientific methodologies of randomized trials and careful clinical observation span all aspects of medicine.

The advent of modern approaches to managing data now provides the rationale for the use of health information technology. Computerized health records, oftentimes shared with patients in a portable format, can avoid duplication of tests and assure that care is coordinated among the patient's various health care providers.

Extraordinary advances in the science and practice of medicine, which have continued to accelerate with each recent edition of this textbook, have transformed the global burden of disease.[4] Life expectancies for men and women are increasing, a greater proportion of deaths are occurring among people older than age 70 years, and far fewer children are dying before the age of 5 years. Nevertheless, huge regional disparities remain, and disability from conditions such as substance abuse, mental health disorders, injuries, diabetes, musculoskeletal disease, and chronic respiratory disease have become increasingly important issues for all health systems.

APPROACH TO THE PATIENT

Patients commonly have complaints (symptoms). These symptoms may or may not be accompanied by abnormalities on examination (signs) or on laboratory testing. Conversely, asymptomatic patients may have signs or laboratory abnormalities, and laboratory abnormalities can occur in the absence of symptoms or signs.

Symptoms and signs commonly define *syndromes,* which may be the common final pathway of a wide range of pathophysiologic alterations. The fundamental basis of internal medicine is that diagnosis should elucidate the pathophysiologic explanation for symptoms and signs so that therapy may improve the underlying abnormality, not just attempt to suppress the abnormal symptoms or signs.

When patients seek care from physicians, they may have manifestations or exacerbations of known conditions, or they may have symptoms and signs that suggest malfunction of a particular organ system. Sometimes the pattern of symptoms and signs is highly suggestive or even pathognomonic for a particular disease process. In these situations, in which the physician is focusing on a particular disease, *Goldman-Cecil Medicine* provides scholarly yet practical approaches to the epidemiology, pathobiology, clinical manifestations, diagnosis, treatment, prevention, and prognosis of entities such as acute myocardial infarction (Chapter 73), chronic obstructive lung disease (Chapter 88), obstructive uropathy (Chapter 123), inflammatory bowel disease (Chapter 141), gallstones (Chapter 155), rheumatoid arthritis (Chapter 264), hypothyroidism (Chapter 226), tuberculosis (Chapter 324), and virtually any known medical condition in adults.

Many patients, however, have undiagnosed symptoms, signs, or laboratory abnormalities that cannot be immediately ascribed to a particular disease or cause. Whether the initial manifestation is chest pain (Chapter 51), diarrhea (Chapter 140), neck or back pain (Chapter 400), or a variety of more than 100 common symptoms, signs, or laboratory abnormalities, *Goldman-Cecil Medicine* provides tables, figures, and entire chapters to guide the approach to diagnosis and therapy (see E-Table 1-1 or table on inside back cover). By virtue of this dual approach to known disease as well as to undiagnosed abnormalities, this textbook, similar to the modern practice of medicine, applies directly to patients regardless of their mode of manifestation or degree of previous evaluation.

The patient-physician interaction proceeds through many phases of clinical reasoning and decision making. The interaction begins with an elucidation of complaints or concerns, followed by inquiries or evaluations to address these concerns in increasingly precise ways. The process commonly requires a careful history or physical examination, ordering of diagnostic tests, integration of clinical findings with test results, understanding of the risks and benefits of the possible courses of action, and careful consultation with the patient and family to develop future plans. Physicians can increasingly call on a growing literature of evidence-based medicine to guide the process so that benefit is maximized while respecting individual variations in different patients. Throughout *Goldman-Cecil Medicine,* the best current evidence is highlighted with specific grade A references that can be accessed directly in the electronic version.

The increasing availability of evidence from randomized trials to guide the approach to diagnosis and therapy should not be equated with "cookbook" medicine. Evidence and the guidelines that are derived from it emphasize proven approaches for patients with specific characteristics. Substantial clinical judgment is required to determine whether the evidence and guidelines apply to individual patients and to recognize the occasional exceptions. Even more judgment is required in the many situations in which evidence is absent or inconclusive. Evidence must also be tempered by patients' preferences, although it is a physician's responsibility to emphasize evidence when presenting alternative options to the patient. The adherence of a patient to a specific regimen is likely to be enhanced if the patient also understands the rationale and evidence behind the recommended option.

To care for a patient as an individual, the physician must understand the patient as a person. This fundamental precept of doctoring includes an understanding of the patient's social situation, family issues, financial concerns, and preferences for different types of care and outcomes, ranging from maximum prolongation of life to the relief of pain and suffering (Chapters 2 and 3). If the physician does not appreciate and address these issues, the science of medicine cannot be applied appropriately, and even the most knowledgeable physician will fail to achieve the desired outcomes.

Even as physicians become increasingly aware of new discoveries, patients can obtain their own information from a variety of sources, some of which are of questionable reliability. The increasing use of alternative and complementary therapies (Chapter 39) is an example of patients' frequent dissatisfaction with prescribed medical therapy. Physicians should keep an open mind regarding unproven options but must advise their patients carefully if such options may carry any degree of potential risk, including the risk that they may be relied on to substitute for proven approaches. It is crucial for the physician to have an open dialogue with the patient and family regarding the full range of options that either may consider.

The physician does not exist in a vacuum, but rather as part of a complicated and extensive system of medical care and public health. In premodern times and even today in some developing countries, basic hygiene, clean water, and adequate nutrition have been the most important ways to promote health and reduce disease. In developed countries, adoption of healthy lifestyles, including better diet (Chapter 213) and appropriate exercise (Chapter 16), is the cornerstone to reducing the epidemics of obesity (Chapter 220), coronary disease (Chapter 52), and diabetes (Chapter 229). Public health interventions to provide immunizations (Chapter 18) and to reduce injuries and the use of tobacco (Chapter 32), illicit drugs (Chapter 34), and excess alcohol (Chapter 33) can collectively produce more health benefits than nearly any other imaginable health intervention.

APPROACH TO THE MEDICAL PROFESSION

In a profession, practitioners put the welfare of clients or patients above their own welfare.[5] Professionals have a duty that may be thought of as a contract with society. The American Board of Internal Medicine and the European Federation of Internal Medicine have jointly proposed that medical professionalism should emphasize three fundamental principles: the primacy of patient welfare, patient autonomy, and social justice.[6] As modern medicine brings a plethora of diagnostic and therapeutic options, the interactions of the physician with the patient and society become more complex and potentially fraught with ethical dilemmas (Chapter 2). To help provide a moral compass that is not only grounded in tradition but also adaptable to modern times, the primacy of patient welfare emphasizes the fundamental principle of a profession. The physician's altruism, which begets the patient's trust, must be impervious to the economic, bureaucratic, and political challenges that are faced by the physician and the patient (Chapter 5).

The principle of patient autonomy asserts that physicians make recommendations but patients make the final decisions. The physician is an expert advisor who must inform and empower the patient to base decisions on scientific data and how these data can and should be integrated with a patient's preferences.

The importance of social justice symbolizes that the patient-physician interaction does not exist in a vacuum. The physician has a responsibility to the individual patient and to broader society to promote access and to eliminate disparities in health and health care.

To promote these fundamental principles, a series of professional responsibilities has been suggested (Table 1-1). These specific responsibilities represent practical, daily traits that benefit the physician's own patients and society as a whole. Physicians who use these and other attributes to improve their patients' satisfaction with care are not only promoting professionalism but also reducing their own risk for liability and malpractice.

An interesting new aspect of professionalism is the increasing reliance on team approaches to medical care, as exemplified by physicians whose roles are defined by the location of their practice—historically in the intensive care unit or emergency department and more recently on the inpatient general hospital floor. Quality care requires coordination and effective communication across inpatient and outpatient sites among physicians who themselves now typically work defined hours.[7] This transition from reliance on a single, always available physician to a team, ideally with a designated coordinator, places new challenges on physicians, the medical care system, and the medical profession.

TABLE 1-1 PROFESSIONAL RESPONSIBILITIES

Commitment to:
Professional competence
Honesty with patients
Patient confidentiality
Maintaining appropriate relations with patients
Improving the quality of care
Improving access to care
Just distribution of finite resources
Scientific knowledge
Maintaining trust by managing conflicts of interest
Professional responsibilities

The changing medical care environment is placing increasing emphasis on standards, outcomes, and accountability. As purchasers of insurance become more cognizant of value rather than just cost (Chapter 12), outcomes ranging from rates of screening mammography (Chapter 198) to mortality rates with coronary artery bypass graft surgery (Chapter 74) become metrics by which rational choices can be made. Clinical guidelines and critical pathways derived from randomized controlled trials and evidence-based medicine can potentially lead to more cost-effective care and better outcomes.

These major changes in many Western health care systems bring with them many major risks and concerns. If the concept of limited choice among physicians and health care providers is based on objective measures of quality and outcome, channeling of patients to better providers is one reasonable definition of better selection and enlightened competition. If the limiting of options is based overwhelmingly on cost rather than measures of quality, outcomes, and patient satisfaction, it is likely that the historical relationship between the patient and the truly professional physician will be fundamentally compromised.

Another risk is that the same genetic information that could lead to more effective, personalized medicine will be used against the very people whom it is supposed to benefit—by creating a stigma, raising health insurance costs, or even making someone uninsurable. The ethical approach to medicine (Chapter 2), genetics (Chapter 40), and genetic counseling provides means to protect against this adverse effect of scientific progress.

In this new environment, the physician often has a dual responsibility: to the health care system as an expert who helps create standards, measures of outcome, clinical guidelines, and mechanisms to ensure high-quality, cost-effective care; and to individual patients who entrust their well-being to that physician to promote their best interests within the reasonable limits of the system. A health insurance system that emphasizes cost-effective care, that gives physicians and health care providers responsibility for the health of a population and the resources required to achieve these goals, that must exist in a competitive environment in which patients can choose alternatives if they are not satisfied with their care, and that places increasing emphasis on health education and prevention can have many positive effects. In this environment, however, physicians must beware of overt and subtle pressures that could entice them to underserve patients and abrogate their professional responsibilities by putting personal financial reward ahead of their patients' welfare. The physician's responsibility to represent the patient's best interests and avoid financial conflicts by doing too little in the newer systems of capitated care provides different specific challenges but an analogous moral dilemma to the historical American system in which the physician could be rewarded financially for doing too much.

In the current health care environment, all physicians and trainees must redouble their commitment to professionalism. At the same time, the challenge to the individual physician to retain and expand the scientific knowledge base and process the vast array of new information is daunting. In this spirit of a profession based on science and caring, *Goldman-Cecil Medicine* seeks to be a comprehensive approach to modern internal medicine.

BIOETHICS IN THE PRACTICE OF MEDICINE

EZEKIEL J. EMANUEL

It commonly is argued that modern advances in medical technology, antibiotics, dialysis, transplantation, and intensive care units have created the bioethical dilemmas that confront physicians in the 21st century. In reality, however, concerns about ethical issues are as old as the practice of medicine itself. The Hippocratic Oath, composed sometime around 400 BC, attests to the need of ancient Greek physicians for advice on how to address the many bioethical dilemmas that they confronted. The Oath addresses issues of confidentiality, abortion, euthanasia, sexual relations between physician and patient, divided loyalties, and, at least implicitly, charity care and executions. Other Hippocratic works address issues such as termination of treatments to dying patients and telling the truth. Whether we agree with the advice dispensed or not, the important point is that many bioethical issues are not created by technology but instead are inherent in medical practice. Technology may make these issues more common and may change the context in which they arise, but many, if not most, bioethical issues that regularly confront physicians are timeless and inherent in the practice of medicine.

Many physicians have been educated that four main principles can be invoked to address bioethical dilemmas: autonomy, nonmaleficence, beneficence, and justice. Autonomy is the idea that people should have the right and freedom to choose, pursue, and revise their own life plans. Nonmaleficence is the idea that people should not be harmed or injured knowingly; this principle is encapsulated in the frequently repeated phrase that a physician has an obligation to "first do no harm"—*primum non nocere*. This phrase is not found either in the Hippocratic Oath or in other Hippocratic writing; the only related, but not identical, Hippocratic phrase is "at least, do not harm." Whereas nonmaleficence is about avoiding harm, beneficence is about the positive actions that the physician should undertake to promote the well-being of his or her patients. In clinical practice, this obligation usually arises from the implicit and explicit commitments and promises surrounding the physician-patient relationship. Finally, there is the principle of justice as the fair distribution of benefits and burdens.

Although helpful in providing an initial framework, these principles have limited value because they are broad and open to diverse and conflicting interpretations. In addition, as is clear with the principle of justice, they frequently are underdeveloped. In any difficult case, the principles are likely to conflict. Conflicting ethical principles are precisely why there are bioethical dilemmas. The principles themselves do not offer guidance on how they should be balanced or specified to resolve the dilemma. These principles, which are focused on the individual physician-patient context, are not particularly helpful when the bioethical issues are institutional and systemic, such as allocating scarce vaccines or organs for transplantation or balancing the risks and benefits of mammograms for women younger than 50 years. Finally, these four principles are not comprehensive. Other fundamental ethical principles and values, such as communal solidarity, duties to future generations, trust, and professional integrity, are important in bioethics but not encapsulated except by deformation in these four principles.

There is no formula or small set of ethical principles that mechanically or magically gives answers to bioethical dilemmas. Instead, medical practitioners should follow an orderly analytic process. First, practitioners need to obtain the facts relevant to the situation. Second, they must delineate the basic bioethical issue. Third, it is important to identify all the crucial principles and values that relate to the case and how they might conflict. Fourth, because many ethical dilemmas have been analyzed previously and subjected frequently to empirical study, practitioners should examine the relevant literature, whether it is commentaries or studies in medical journals, legal cases, or books. With these analyses, the particular dilemma should be reexamined; this process might lead to reformulation of the issue and identification of new values or new understandings of existing values. Fifth, with this information, it is important to distinguish clearly unethical practices from a range of ethically permissible actions. Finally, it is important not only to come to some resolution of the case but also to state clearly the reasons behind the decisions, that is, the interpretation of the principles used and how values were balanced. Although unanimity and consensus may be desirable ideals, reasonable people frequently disagree about how to resolve ethical dilemmas without being unethical or malevolent.

A multitude of bioethical dilemmas arise in medical practice, including issues of genetics, reproductive choices, and termination of care. In clinical practice, the most common issues revolve around informed consent, termination of life-sustaining treatments, euthanasia and physician-assisted suicide, and conflicts of interest.

PHYSICIAN-PATIENT RELATIONSHIP: INFORMED CONSENT

History

It commonly is thought that the requirement for informed consent is a relatively recent phenomenon. Suggestions about the need for a patient's informed consent can be found as far back as Plato, however. The first

recorded legal case involving informed consent is the 1767 English case of *Slater v. Baker and Stapleton,* in which two surgeons refractured a patient's leg after it had healed improperly. The patient claimed they had not obtained consent. The court ruled:

> *[I]t appears from the evidence of the surgeon that it was improper to disunite the callous without consent; this is the usage and law of surgeons: then it was ignorance and unskillfulness in that very particular, to do contrary to the rule of the profession, what no surgeon ought to have done.*

Although there may be some skepticism about the extent of the information disclosed or the precise nature of the consent obtained, the notable fact is that an 18th-century court declared that obtaining prior consent of the patient is not only the usual practice but also the ethical and legal obligation of surgeons. Failure to obtain consent is incompetent and inexcusable. In contemporary times, the 1957 case of *Salgo v. Leland Stanford Junior University Board of Trustees* constitutes a landmark by stating that physicians have a positive legal obligation to disclose information about risks, benefits, and alternatives to patients; this decision popularized the term *informed consent.*

Definition and Justification

Informed consent is a person's autonomous authorization of a physician to undertake diagnostic or therapeutic interventions for himself or herself. In this view, the patient understands that he or she is taking responsibility for the decision while empowering someone else, the physician, to implement it. However, agreement to a course of medical treatment does not necessarily qualify as informed consent.

There are four fundamental requirements for valid informed consent: mental capacity, disclosure, understanding, and voluntariness. Informed consent assumes that people have the mental capacity to make decisions; disease, development, or medications can compromise patients' mental capacity to provide informed consent. Adults are presumed to have the legal competence to make medical decisions, and whether an adult is incompetent to make medical decisions is a legal determination. Practically, physicians usually decide whether patients are competent on the basis of whether patients can understand the information disclosed, appreciate its significance for their own situation, and use logical and consistent thought processes in decision making. Incompetence in medical decision making does not mean a person is incompetent in all types of decision making and vice versa. Crucial information relevant to the decision must be disclosed, usually by the physician, to the patient. The patient should understand the information and its implications for his or her interests and life goals. Finally, the patient must make a voluntary decision (i.e., one without coercion or manipulation by the physician). It is a mistake to view informed consent as an event, such as the signing of a form. Informed consent is viewed more accurately as a process that evolves during the course of diagnosis and treatment.

Typically, the patient's autonomy is the value invoked to justify informed consent. Other values, such as bodily integrity and beneficence, have also been cited, especially in early legal rulings.

Empirical Data

Fairly extensive research has been done on informed consent. In general, studies show that in clinical situations, physicians frequently do not communicate all relevant information for informed decision making. In a study of audiotapes from 1057 outpatient encounters, physicians mentioned alternatives in only 11.3% of cases, provided pros and cons of interventions in only 7.8% of situations, and assessed the patient's understanding of the information in only 1.5% of decisions. The more complex the medical decisions, the more likely it was that the elements of informed consent would be fulfilled. Importantly, data suggest that disclosure is better in research settings, both in the informed consent documents and in the discussions. For instance, in recorded interactions between researchers and prospective participants, the major elements of research, such as that the treatment was investigational and the risks and benefits of treatment, were disclosed in more than 80% of interactions. Greater disclosure in the research setting may be the consequence of requiring a written informed consent document that has been reviewed by an independent committee, such as an institutional review board or a research ethics committee. Some have suggested that for common medical interventions, such as elective surgery, standardized informed consent documents should include the risks and benefits as quantified in randomized controlled trials, relevant data on the surgeon, the institution's clinical outcomes for the procedure, and a list of acceptable alternatives.[1]

Patients frequently fail to recall crucial information disclosed, although they usually think they have sufficient information for decision making. Whether patients fail to recall key information because they are overwhelmed by the information or because they do not find much of it salient to their decision is unclear. The issue is what patients understand at the point of decision making, not what they recall later.

Studies aimed at improving informed consent in the clinical setting suggest that interactive media, such as videos and interactive computer software, can improve understanding by patients. Conversely, data on shared decision making show that interactive media do not improve participants' understanding, whereas more personal interaction, whether as an additional telephone call by a research nurse or as an additional face-to-face meeting, does enhance understanding.[2]

One of the most important results of empirical research on informed consent is the gap between information and decision making. Many studies show that most patients want information, but far fewer prefer decision-making authority. One study showed that most patients wanted information, but only about one third desired decision-making authority, and patients' decision-making preferences were not correlated with their information-seeking preferences. Several investigators found that patients' preference for decision-making authority increases with higher educational levels and declines with advancing age. Most important, the more serious the illness, the more likely patients are to prefer that physicians make the decisions. Several studies suggest that patients who have less of a desire to make their own decisions generally are more satisfied with how the decisions were made.

Practical Considerations

Implementing informed consent raises concerns about the extent of information to be disclosed and exceptions to the general requirement. A major area of ethical and legal disagreement has been what information to disclose and how to disclose it. As a practical matter, physicians should disclose at least six fundamental elements of information to patients: (1) diagnosis and prognosis; (2) nature of the proposed intervention; (3) alternative interventions, including no treatment; (4) risks associated with each alternative; (5) benefits of each alternative; and (6) likely outcomes of these alternatives (Table 2-1). Because risk is usually the key worry of physicians, it generally is recommended that physicians disclose (1) the nature of the risks, (2) their magnitude, (3) the probability that each risk will occur, and (4) when the consequence might occur.[3] Increasingly, these disclosures should include data both from clinical trials as well as the actual data from the institution and physician performing the test and treatments. Some argue that minor risks need not be disclosed. In general, all serious risks, such as death, paralysis, stroke, infections, or chronic pain, even if rare, should be disclosed, as should common risks.

The central problem is that the physician should provide this detailed information within reasonable time constraints and yet not overwhelm patients with complex information in technical language. The historical constraint of office time is no longer tenable. Interactive electronic media, which patients can view at home on their own time, can facilitate the transfer of information outside of the physician's office. Different states have adopted two contrasting legal standards defining how much information should be disclosed. The *physician* or *customary* standard, adapted from malpractice law, states that the physician should disclose information "which a reasonable medical practitioner would make under the same or similar circumstances." Conversely, the *reasonable person* or *lay-oriented* standard states that physicians should disclose all information that a "reasonable person in the patient's circumstances would find material to" the medical decision. The physician standard is factual and can be determined empirically, but the patient-oriented standard, which is meant to engage physicians with patients, is hypothetical. Currently, each standard is used by about half the states.

TABLE 2-1 FUNDAMENTAL ELEMENTS FOR DISCLOSURE TO PATIENTS

Diagnosis and prognosis
Nature of proposed intervention
Reasonable alternative interventions
Risks associated with each alternative intervention
Benefits associated with each alternative intervention
Probable outcomes of each alternative intervention

There are exceptions to the requirements of informed consent. In emergency situations, consent can be assumed because patients' interests concentrate on survival and retaining maximal mental and physical functioning; as a result, reasonable persons would want treatment. In some circumstances, physicians may believe the process of informed consent could pose a serious psychological threat. In rare cases, the "therapeutic privilege" promoting a patient's well-being trumps autonomy, but physicians should be wary of invoking this exception too readily.

If patients are deemed incompetent, family members—beginning with spouse, children, parents, siblings, then more distant relatives—usually are selected as surrogates or proxies, although there may be concerns about conflicting interests or knowledge of the patient's wishes. In the relatively rare circumstance in which a patient formally designated a proxy, that person has decision-making authority.

The *substituted judgment* standard states that the proxy should choose what the patient would choose if he or she were competent. The *best interests* standard states that the proxy should choose what is best for the patient. Frequently, it is not clear how the patient would have decided because the situation was not discussed with the patient and he or she left no living will. Similarly, what is best for a patient is controversial because there are usually tradeoffs between quality of life and survival. These problems are exacerbated because a proxy's predictions about a patient's quality of life are poor; proxies tend to underestimate patients' functional status and satisfaction. Similarly, proxy predictions are inaccurate regarding life-sustaining preferences when the patient is mentally incapacitated. Families tend to agree with patients about two thirds of the time in deciding whether to provide life-sustaining treatments if the patient became demented, when chance alone would generate agreement in 50% of the cases. Such confusion about how to decide for incapacitated patients can create conflicts among family members or between the family and medical providers. In such circumstances, an ethics consultation may be helpful.

TERMINATION OF MEDICAL INTERVENTIONS

History

Since the start of medicine, it has been viewed as ethical to withhold medical treatments from the terminally ill and "let nature take its course," while keeping the patient as comfortable as possible.[4] Hippocrates argued that physicians should "refuse to treat those [patients] who are overmastered by their disease." In the 19th century, prominent American physicians advocated withholding of cathartic and emetic "treatments" from the terminally ill and using ether to ease pain at the end of life. John Collins Warren, who wrote *Etherization: with Surgical Remarks* in 1848, included a chapter on using ether to ease the pain of a cancer patient's death. The editors of *The Lancet,* in 1900, argued that physicians should intervene to ease the pain of death and that they did not have an obligation to prolong a clearly terminal life. The contemporary debate on terminating care began in 1976 with the *Quinlan* case, in which the New Jersey Supreme Court ruled that patients had a right to refuse life-sustaining interventions on the basis of a right of privacy and that the family could exercise the right for a patient in a persistent vegetative state.

Definition and Justification

It generally is agreed that all patients have a right to refuse medical interventions. Ethically, this right is based on the patient's autonomy and is implied by the doctrine of informed consent. Legally, state courts have cited the right to privacy, right to bodily integrity, or common law to justify the right to refuse medical treatment. In the 1990 *Cruzan* case and in the subsequent physician-assisted suicide cases, the U.S. Supreme Court affirmed that there is a "constitutionally protected right to refuse lifesaving hydration and nutrition." The Court stated that "[A] liberty interest [based on the 14th Amendment] in refusing unwanted medical treatment may be inferred from our prior decisions." All patients have a constitutional and an ethical right to refuse medical interventions. These rulings were the basis of the consistent state and federal court rulings to permit the husband to terminate artificial nutrition and hydration in the *Schiavo* case.

Empirical Data

Data show that termination of medical treatments is now the norm, and the trend has been to stop medical interventions more frequently based on the preferences of patients and their surrogate decision makers.[5] More than 85% of Americans die without cardiopulmonary resuscitation, and more than 90% of decedents in intensive care units do not receive cardiopulmonary resuscitation. Of decedents in intensive care units, more than 85% die after the withholding or withdrawal of medical treatments, with an average of 2.6 interventions being withheld or withdrawn per decedent.

Despite extensive public support for use of advance care directives and the passage of the Patient Self-Determination Act mandating that health care institutions inform patients of their right to complete such documents, less than 30% of Americans have completed one.[6] Even among severely or terminally ill patients, less than 50% have an advance directive in their medical record. Data suggest that more than 40% of patients required active decision-making about terminating medical treatments in their final days, but more than 70% lacked decision-making capacity, thereby emphasizing the importance of advance directives. Efforts to improve completion of advance care directives have generated mixed results. In La Crosse County, Wisconsin, for example, after health care organizations in the county added an "Advance Directive" section to their electronic medical records, 90% of decedents had some type of advance directive. Unfortunately, even successful pilot efforts like La Crosse County's have not been adopted or easily scaled. A persistent problem has been that even when patients complete advance care directives, the documents frequently are not available, physicians do not know they exist, or they tend to be too general or vague to guide decisions. The increasing use of electronic health records should make it possible for advance directives to be available whenever and wherever the patient presents to a health care provider. Although electronic health records will help in making existing advance directives available, they will not solve the problem of actually having a conversation between the physician and the patient about advance care planning. Starting that conversation still seems to be a persistent barrier.

Just as proxies are poor at predicting patients' wishes, data show that physicians are probably even worse at determining patients' preferences for life-sustaining treatments. In many cases, life-sustaining treatments are continued even when patients or their proxies desire them to be stopped. Conversely, many physicians discontinue or never begin interventions unilaterally without the knowledge or consent of patients or their surrogate decision makers. These discrepancies emphasize the importance of engaging patients early in their care about treatment preferences.

Practical Considerations

There are many practical considerations in enacting this right (Table 2-2). First, patients have a right to refuse any and all medical interventions, from blood transfusions and antibiotics to respirators, artificial hydration, and nutrition. Although initiation of cardiopulmonary resuscitation was the focus of the early court cases, this issue is viewed best as addressing just one of the many medical interventions that can be stopped or withheld.

The question of what medical interventions can be terminated—or not started—is a recurrent topic of debate among physicians and other health care providers. The fact is that any treatment prescribed by a physician and administered by a health care provider can be stopped. The issue is not whether the treatment is ordinary, extraordinary, or heroic, or whether it is high technology or low technology. Treatments that can be stopped include not only ventilators, artificial nutrition, and hydration but also dialysis, pacemakers, ventricular assist devices, antibiotics, and any medications.

Second, there is no ethical or legal difference between withholding an intervention and withdrawing it. If a respirator or other treatment is started because physicians are uncertain whether a patient would have wanted it, they always can stop it later when information clarifies the patient's wishes. Although physicians and nurses might find stopping a treatment to be more difficult psychologically, withdrawal is ethically and legally permitted—and required—when it is consonant with the patient's wishes.

Third, competent patients have the exclusive right to decide about terminating their own care.[7] If there is a conflict between a competent patient and his or her family, the patient's wishes are to be followed. It is the patient's right to refuse treatment, not the family's right. For incompetent patients, the situation is more complex; if the patients left clear indications of their wishes, whether as explicit oral statements or as written advance care directives, these wishes should be followed. Physicians should not be overly concerned about the precise form patients use to express their wishes; because patients have a constitutional right to refuse treatment, the real concern is whether the wishes are clear and relevant to the situation. If an incompetent patient did not leave explicit indications of his or her wishes or designate a proxy decision maker, the physician should identify a surrogate decision maker and rely on the decision maker's wishes while being cognizant of the potential problems noted. There is a potential problem in terminating life-sustaining care to patients who are permanently incompetent but still conscious. Some state courts have restricted what treatments a proxy decision maker can terminate,

TABLE 2-2 PRACTICAL CONSIDERATIONS IN TERMINATION OF MEDICAL TREATMENTS

PRACTICAL QUESTION	ANSWER
Is there a legal right to refuse medical interventions?	Yes. The U.S. Supreme Court declared that competent people have a constitutionally protected right to refuse unwanted medical treatments based on the 14th Amendment.
What interventions can be legally and ethically terminated?	Any and all interventions (including respirators, antibiotics, pacemakers, ventricular assist devices, intravenous or enteral nutrition and hydration) can be legally and ethically terminated.
Is there a difference between withholding life-sustaining interventions and withdrawing them?	No. The consensus is that there is no important legal or ethical difference between withholding and withdrawing medical interventions. Stopping a treatment once begun is just as ethical as never having started it.
Whose view about terminating life-sustaining interventions prevails if there is a conflict between the patient and family?	The views of a competent adult patient prevail. It is the patient's body and life.
Who decides about terminating life-sustaining interventions if the patient is incompetent?	If the patient appointed a proxy or surrogate decision maker when competent, that person is legally empowered to make decisions about terminating care. If no proxy was appointed, there is a legally designated hierarchy, usually (1) spouse, (2) adult children, (3) parents, (4) siblings, and (5) available relatives.
Are advance care directives legally enforceable?	Yes. As a clear expression of the patient's wishes, they are a constitutionally protected method for patients to exercise their right to refuse medical treatments. In almost all states, clear and explicit oral statements are legally and ethically sufficient for decisions about withholding or withdrawing medical interventions.

TABLE 2-3 DEFINITIONS OF ASSISTED SUICIDE AND EUTHANASIA

TERM	DEFINITION
Voluntary active euthanasia	Intentional administration of medications or other interventions to cause the patient's death with the patient's informed consent
Involuntary active euthanasia	Intentional administration of medications or other interventions to cause the patient's death when the patient was competent to consent but did not consent (e.g., the patient may not have been asked)
Nonvoluntary active euthanasia	Intentional administration of medications or other interventions to cause the patient's death when the patient was incompetent and was mentally incapable of consenting (e.g., the patient might have been in a coma)
Passive euthanasia	Withholding or withdrawal of life-sustaining medical treatments from a patient to let him or her die (termination of life-sustaining treatments)—a poor term that should not be used
Indirect euthanasia	Administration of narcotics or other medications to relieve pain with the incidental consequence of causing sufficient respiratory depression to result in the patient's death
Physician-assisted suicide	A physician provides prescription medications or other interventions to a patient with the understanding that the patient can use them to commit suicide

thereby requiring the incompetent patient to have given very specific instructions about the particular treatments he or she does not want to receive and the conditions under which care should be withheld or withdrawn. This requirement severely limits the authority and power of proxy decision makers in these cases.

Fourth, the right to refuse medical treatment does not translate into a right to demand any treatment, especially treatments that have no pathophysiologic rationale, have already failed, or are known to be harmful. Futility has become a justification to permit physicians unilaterally to withhold or withdraw treatments despite the family's requests for treatment. Some states, such as Texas, have enacted futility laws, which prescribe procedures by which physicians can invoke futility either to transfer a patient or to terminate interventions. However, the principle of futility is not easy to implement in medical practice. Initially, some commentators advocated that an intervention was futile when the probability of success was 1% or lower. Although this threshold seems to be based on empirical data, it is a covert value judgment. Because the declaration of futility is meant to justify unilateral determinations by physicians, it generally has been viewed as an inappropriate assertion that undermines physician-patient communication and violates the principle of shared decision making. Similar to the distinction between ordinary and extraordinary, futility is viewed increasingly as more obfuscating than clarifying, and it is being invoked much less often.

ASSISTED SUICIDE AND EUTHANASIA

History

Since Hippocrates, euthanasia and physician-assisted suicide have been controversial issues. In 1905, a bill was introduced into the Ohio legislature to legalize euthanasia; it was defeated. In the mid-1930s, similar bills were introduced and defeated in the British Parliament and the Nebraska legislature. As of January 2014, physician-assisted suicide is legal in Oregon and Washington State, based on statewide public referenda, and in Vermont, based on legislation passed in May 2013. Both euthanasia and physician-assisted suicide are legal in the Netherlands, Belgium, and Luxembourg, and physician-assisted suicide is legal in Switzerland. The Montana Supreme Court did not recognize a constitutional right to physician-assisted suicide, but it ruled that the law permitting the termination of life-sustaining treatment protected physicians from prosecution if they helped hasten the death of a consenting, rational, terminally ill patient.

Definition and Justification

The terms *euthanasia* and *physician-assisted suicide*[8] require careful definition (Table 2-3). So-called passive and indirect euthanasia are misnomers and are not instances of euthanasia, and both are deemed ethical and legal.

There are four arguments against permitting euthanasia and physician-assisted suicide. First, Kant and Mill thought that autonomy did not permit the voluntary ending of the conditions necessary for autonomy, and as a result, both philosophers were against voluntary enslavement and suicide. Consequently, the exercise of autonomy cannot include the ending of life because that would mean ending the possibility of exercising autonomy. Second, many dying patients may have pain and suffering because they are not receiving appropriate care, and it is possible that adequate care would relieve much pain and suffering (Chapter 3). Although a few patients still may experience uncontrolled pain and suffering despite optimal end-of-life care, it is unwise to use the condition of these few patients as a justification to permit euthanasia or physician-assisted suicide for any dying patient. Third, there is a clear ethical distinction between intentional ending of a life and termination of life-sustaining treatments. The actual acts are different—injecting a life-ending medication, such as a muscle relaxant, or providing a prescription for one is not the same as removing or refraining from introducing an invasive medical intervention. Finally, adverse consequences of permitting euthanasia and physician-assisted suicide must be considered. There are disturbing reports of involuntary euthanasia in the Netherlands and Belgium, and many worry about coercion of expensive or burdensome patients to accept euthanasia or physician-assisted suicide. Permitting euthanasia and physician-assisted suicide is likely to lead to further intrusions of lawyers, courts, and legislatures into the physician-patient relationship.

There are four parallel arguments for permitting euthanasia and physician-assisted suicide. First, it is argued that autonomy justifies euthanasia and physician-assisted suicide. To respect autonomy requires permitting individuals to decide when it is better to end their lives by euthanasia or physician-assisted suicide. Second, beneficence—furthering the well-being of individuals—supports permitting euthanasia and physician-assisted suicide. In some cases, living can create more pain and suffering than death; ending a painful life relieves more suffering and produces more good. Just the reassurance of having the option of euthanasia or physician-assisted suicide, even if people do not use it, can provide "psychological insurance" and be

beneficial to people. Third, euthanasia and physician-assisted suicide are no different from termination of life-sustaining treatments that are recognized as ethically justified. In both cases, the patient consents to die; in both cases, the physician intends to end the patient's life and takes some action to end the patient's life; and in both cases, the final result is the same: the patient's death. With no difference in the patient's consent, the physician's intention, or the final result, there can be no difference in the ethical justification. Fourth, the supposed slippery slope that would result from permitting euthanasia and physician-assisted suicide is not likely. The idea that permitting euthanasia and physician-assisted suicide would undermine the physician-patient relationship or lead to forced euthanasia is completely speculative and not borne out by the available data.

In its 1997 decisions, the U.S. Supreme Court stated that there is no constitutional right to euthanasia and physician-assisted suicide but that there also is no constitutional prohibition against states legalizing these interventions. Consequently, the legalization of physician-assisted suicide in Oregon, Vermont, and Washington State was constitutional.

Empirical Data

Attitudes and practices related to euthanasia and physician-assisted suicide have been studied extensively. First, surveys consistently indicate that between 50 and 80% of the American and British public support legalizing euthanasia and physician-assisted suicide for terminally ill patients who are suffering intractable pain.[9] However, public support declines significantly for euthanasia and physician-assisted suicide in other circumstances, such as for psychological reasons.[10] Physicians tend to be much less supportive of euthanasia and physician-assisted suicide, with oncologists, palliative care physicians, and geriatricians among the least supportive. Among American and British physicians, the majority opposes legalizing either practice. Second, approximately 25% of American physicians have received requests for euthanasia or physician-assisted suicide, including about 50% of oncologists. Third, multiple studies indicate that less than 5% of American physicians have performed euthanasia or physician-assisted suicide. Among oncologists, 4% have performed euthanasia and 11% have performed physician-assisted suicide during their careers. Fourth, in many cases, the safeguards are violated. One study found that in 54% of euthanasia cases, it was the family who made the request; in 39% of euthanasia and 19% of physician-assisted suicide cases, the patient was depressed; in only half of the cases was the request repeated.

In the Netherlands and Belgium, where euthanasia and physician-assisted suicide are legal, less than 2% of all deaths are by these measures, with 0.4 to 1.8% of all deaths as the result of euthanasia without the patient's consent.[11] Since the practice of assisted suicide was legalized in Oregon in 1997, a cumulative 0.2% of all deaths are by physician-assisted suicide.

Counterintuitively, data indicate that it is not pain that primarily motivates requests for euthanasia or physician-assisted suicide but rather psychological distress, especially depression and hopelessness. Interviews with physicians and with patients with amyotrophic lateral sclerosis, cancer, or infection with human immunodeficiency virus show that pain is not associated with interest in euthanasia or physician-assisted suicide; instead, depression and hopelessness are the strongest predictors of interest. Studies of patients in Australia and the Netherlands confirm the importance of depression in motivating requests for euthanasia. The desire to avoid dependence and loss of dignity are key motivations.

Finally, data from the Netherlands and the United States suggest that there are significant problems in performing euthanasia and physician-assisted suicide. Dutch researchers reported that physician-assisted suicide causes complications in 7% of cases, and in 15% of cases, the patients did not die, awoke from coma, or vomited up the medication. Ultimately, in nearly 20% of physician-assisted suicide cases, the physician ended up injecting the patient with life-ending medication, converting physician-assisted suicide to euthanasia. These data raise serious questions about how to address complications of physician-assisted suicide when euthanasia is illegal or unacceptable.

Practical Considerations

There is widespread agreement that if euthanasia and physician-assisted suicide are used, they should be considered only after all reasonable attempts at physical and psychological palliation have failed. A series of safeguards have been developed and embodied in the Oregon and the Dutch procedures, as follows: (1) the patient must be competent and must request euthanasia or physician-assisted suicide repeatedly and voluntarily; (2) the patient must have pain or other suffering that cannot be relieved by optimal palliative interventions; (3) there should be a waiting period to ensure that the patient's desire for euthanasia or physician-assisted suicide is stable and sincere; and (4) the physician should obtain a second opinion from an independent physician. Oregon and Washington State require patients to be terminally ill, whereas the Netherlands, Belgium, and Switzerland have no such requirement. Although there have been some prosecutions in the United States, there have been no convictions—except for Dr. Kevorkian—when physicians and others have participated in euthanasia and physician-assisted suicide.

FINANCIAL CONFLICTS OF INTEREST

History

Worrying about how payment and fees affect medical decisions is not new. In 1899, a physician reported that more than 60% of surgeons in Chicago were willing to provide a 50% commission to physicians for referring cases. He subsequently argued that in some cases, this fee splitting led to unnecessary surgical procedures. A 1912 study by the American Medical Association confirmed that fee splitting was a common practice. Selling patent medicines and patenting surgical instruments were other forms of financial conflicts of interest thought to discredit physicians a century ago. In the 1990s, the ethics of capitation for physician services and pharmaceutical prescriptions and payments by pharmaceutical and biotechnology companies to clinical researchers and practitioners raised the issue of financial conflicts of interest.

Definition and Justification

It commonly is argued that physicians have certain primary interests: (1) to promote the well-being of their patients, (2) to advance biomedical research, (3) to educate future physicians, and, more controversially, (4) to promote public health (Table 2-4). Physicians also have other, secondary interests, such as earning income, raising a family, contributing to the profession, and pursuing avocational interests, such as hobbies. These secondary interests are not evil; typically, they are legitimate, even admirable. A conflict of interest occurs when one of these secondary interests compromises pursuit of a primary interest, especially the patient's well-being.

Conflicts of interest are problematic because they can or appear to compromise the integrity of physicians' judgment, compromising the patient's well-being or research integrity. Conflict of interest can induce a physician to do something—perform a procedure, fail to order a test, or distort data—that would not be in a patient's best interest. These conflicts can undermine the trust of patients and the public, not only in an individual physician but also in the entire medical profession. Even the appearance of conflicts of interest can be damaging because it is difficult for patients and the public "to determine what motives have influenced a professional decision." The focus is on financial conflicts of interest, not because they are worse than other types of conflicts, but rather because they are more pervasive and more easily identified and regulated compared with other conflicts. Since ancient times, the ethical norm on conflicts has been clear: the physician's primary obligation is to patients' well-being, and a physician's personal financial well-being should not compromise this duty.

Empirical Data

Financial conflicts are not rare but are frequently under-reported.[12] The increased use of medical services and escalating health care spending, sometimes without clear benefit to patients, have been linked, at least statistically, to ownership of imaging facilities and referral to specialty hospitals owned by physicians. In Florida, it was estimated that nearly 40% of physicians were involved as owners of freestanding facilities to which they referred patients. In one study, 4 to 4.5 times more imaging examinations were ordered by self-referring physicians than by physicians who referred patients to radiologists. Similarly, patients referred to joint-venture physical therapy facilities have an average of 16 visits compared with 11 at non–joint-venture facilities. A recent study of urologists found that those who had integrated radiation

TABLE 2-4 PRIMARY INTERESTS OF PHYSICIANS

Promotion of the health and well-being of their patients
Advancement of biomedical knowledge through research
Education of future physicians and health care providers
Promotion of the public health

facilities into their practices increased their use of the radiation by 2.5 times compared with urologists who did not have financial relationships with radiation facilities.[13] There are no comparable data on the influence of capitation on physicians' judgment.

Similarly, multiple studies have shown that interaction with pharmaceutical representatives can lead to prescribing of new drugs, nonrational prescribing, and decreased use of generic drugs by physicians. Industry funding for continuing medical education payment for travel to educational symposia increases prescribing of the sponsor's drug.

Regarding researcher conflicts of interest, the available data suggest that corporate funding does not compromise the design and methodology of clinical research; in fact, commercially funded research may be methodologically more rigorous than government- or foundation-supported research. Conversely, data suggest that financial interests do distort researchers' interpretation of data. The most important impact of financial interests, however, appears to be on dissemination of research studies. Growing evidence suggests the suppression or selective publication of data unfavorable to corporate sponsors but the repeated publication of favorable results.

Practical Considerations

First, financial conflicts of interest are inherent in any profession when the professional earns income from rendering a service. Second, conflicts come in many different forms, from legitimate payment for services rendered to investments in medical laboratories and facilities, drug company dinners and payment for attendance at meetings, payment for enrolling patients in clinical research trials, and consultation with companies.

Third, in considering how to manage conflicts, it is important to note that people are poor judges of their own potential conflicts. Individuals often cannot distinguish the various influences that guide their judgments, do not think of themselves as bad, and do not imagine that payment shapes their judgments. Physicians tend to be defensive about charges of conflicts of interest. In addition, conflicts tend to act insidiously, subtly changing practice patterns so that they then become what appear to be justifiable norms.

Fourth, rules—whether laws, regulations, or professional standards—to regulate conflicts of interest are based on two considerations: (1) the likelihood that payment or other secondary interests would create a conflict and (2) the magnitude of the potential harm if there is compromised judgment. Rules tend to be of three types: (1) disclosure of conflicts, (2) management of conflicts, and (3) outright prohibition. Federal law bans certain types of self-referral of physicians in the Medicare program. The American Medical Association and the Pharmaceutical Research and Manufacturers of America have established joint rules that permit physicians to accept gifts of minimal value but "refuse substantial gifts from drug companies, such as the costs of travel, lodging, or other personal expenses . . . for attending conferences or meetings." Additionally, the Physician Payment Sunshine Act, which was passed in 2010 as part of the Affordable Care Act and went into effect in August 2013, requires that drug and device manufacturers report all payments and transfers of value given to physicians to the Centers for Medicare and Medicaid Services so that information can be published on a searchable public website.

Fifth, there is much emphasis on disclosure of conflicts, with the implicit idea being that sunshine is the best disinfectant. Disclosure may be useful in publications, but it is unclear whether this is a suitable safeguard in the clinical setting. Disclosure just may make patients worry more. Patients may have no context in which to place the disclosure or to evaluate the physician's clinical recommendation, and patients may have few other options in selecting a physician or getting care, especially in an acute situation. Furthermore, self-disclosure often is incomplete, even when required.

Finally, some conflicts can be avoided by a physician's own action. Physicians can refuse to engage in personal investments in medical facilities or to accept gifts from pharmaceutical companies at relatively little personal cost. In other circumstances, the conflicts may be institutionalized, and minimizing them can occur only by changing the way organizations structure reimbursement incentives. Capitation encourages physicians to limit medical services, and its potentially adverse effects are likely to be managed by institutional rules rather than by personal decisions.

FUTURE DIRECTIONS

In the near future, as genetics moves from the research to the clinical setting, practicing physicians are likely to encounter issues surrounding genetic testing, counseling, and treatment. The use of genetic tests without the extensive counseling so common in research studies would alter the nature of the bioethical issues. Because these tests have serious implications for the patient and others, scrupulous attention to informed consent must occur. The bioethical issues raised by genetic tests for somatic cell changes, such as tests that occur commonly in cancer diagnosis and risk stratification, are no different from the issues raised with the use of any laboratory or radiographic test.

In some cases, ethics consultation services may be of assistance in resolving bioethical dilemmas, although current data suggest that consultation services are used mainly for problems that arise in individual cases and are not used for more institutional or policy problems.

CARE OF DYING PATIENTS AND THEIR FAMILIES

ROBERT ARNOLD

By 2030, 20% of the U.S. population will be older than 65 years, and people older than 85 years constitute the fastest growing segment of the population. Owing to successes in public health and medicine, many of these people will live the last years of their lives with chronic medical conditions such as cirrhosis, end-stage kidney disease, heart failure, and dementia. Even human immunodeficiency virus (HIV) and many cancers, once considered terminal, have turned into chronic diseases.

The burden associated with these illnesses and their treatments is high. Chronically ill patients report multiple physical and psychological symptoms that lower their quality of life. The economic pressures associated with medical care adversely affect patients' socioeconomic status and cause family stress, especially among caregivers, who spend 20 or more hours a week helping their loved ones.

Palliative care, which was developed to decrease the burden associated with chronic illness, emphasizes patient- and family-centered care that optimizes quality of life by anticipating, preventing, and treating suffering. Palliative care throughout the continuum of illness addresses physical, intellectual, emotional, social, and spiritual needs while facilitating the patient's autonomy, access to information, and choice. Palliative care and services, which are coordinated by an interdisciplinary team, are available concurrently with or independent of curative or life-prolonging care. Palliative and nonpalliative health care providers should collaborate and communicate about care needs while focusing on peace and dignity throughout the course of illness, during the dying process, and after death.

Five points deserve special emphasis. First, palliative care can be delivered at any time during the course of an illness and is often provided concomitantly with disease-focused, life-prolonging therapy. Waiting until a patient is dying to provide palliative care is a serious error. For example, most elderly patients with chronic incurable illnesses, who might benefit from palliative care, are in the last 10 years of their lives but do not consider themselves to be dying. If palliative care is to have an impact on patients' lives, it should be provided earlier in a patient's illness, in tandem with other treatments. Second, prediction is an inexact science. Although many cancers have a predictable trajectory in the last 3 to 6 months of life, for most illnesses, doctors rarely can accurately predict whether a patient is in the last 6 months

of life[1] (E-Fig. 3-1). Third, palliative care primarily focuses on the illness's burden rather than treating the illness itself. Because these burdens can be physical, psychological, spiritual, or social, good palliative care requires a multidisciplinary approach. Fourth, palliative care takes the family unit as the central focus of care. Treatment plans must be developed for both the patient and the family. Fifth, palliative care recognizes that medical treatments are not uniformly successful and that patients die. At some point in a patient's illness, the treatments may cause more burden than benefit. Palliative care recognizes this reality and starts with a discussion of the patient's goals and the development of an individualized treatment plan.

Many people confuse palliative care with hospice—an understandable confusion because hospices epitomize the palliative care philosophy. The two, however, are different. In the United States, hospice provides palliative care, primarily at home, for patients who have a life expectancy of 6 months or less and who are willing to forgo life-prolonging treatments. However, the requirement that patients must have a life expectancy of 6 months or less limits hospice's availability, as does the requirement that patients give up expensive and potentially life-prolonging treatments. Moreover, because doctors and patients often are unwilling to cease these treatments until very late in the disease course, so are most patients.

Palliative care is both a subspeciality and a domain of good internal medicine.[2] Given the need for palliative care, every clinician must be able to provide basic palliative care, and subspecialties such as oncology need special expertise.

PALLIATIVE CARE DOMAINS

Palliative care is a holistic discipline with physical, psychological, spiritual, existential, social, and ethical domains. When caring for patients with chronic life-limiting illness, good palliative care requires that the following questions be addressed:

Is the Patient Physically Comfortable?

Across many chronic conditions, patients have a large number of inadequately treated physical symptoms (Table 3-1). The reasons are multifactorial and range from inadequate physician education, to societal beliefs regarding the inevitability of suffering in chronic illness, to public concerns regarding opioids, to the lack of evidence-based treatments in noncancer patients.

The first step to improve symptom management is a thorough assessment. Standardized instruments such as the Brief Pain Inventory (Fig. 3-1) measure both the patient's symptoms and the effect of those symptoms on the patient's life. Use of standardized instruments assures that physicians will identify overlooked or underreported symptoms and, as a result, will enhance the satisfaction of both the patient and family.

The evidence for the treatment of end-stage symptoms continues to improve. The use of nonsteroidal anti-inflammatory agents and opioids can result in effective pain management in more than 75% of patients with cancer. Advances such as intrathecal pumps and neurolytic blocks are helpful in the remaining 25% (Chapter 30). The use of oxygen is not helpful for refractory dyspnea except when hypoxia has been documented, whereas use of medications for depression often can be helpful (Chapter 397).

Is the Patient Psychologically Suffering?

Patients may be physically comfortable but still suffering. Psychological symptoms and syndromes such as depression, delirium, and anxiety are common in patients with life-limiting or chronic illnesses. It may be difficult to determine whether increased morbidity and mortality are caused by the physical effects of the illness or by the psychological effects of depression and anxiety on energy, appetite, or sleep. Screening questions focusing on mood (e.g., "Have you felt down, depressed, and hopeless most of the time for the past 2 weeks?") and anhedonism (e.g., "Have you found that little brings you pleasure or joy in the past 2 weeks?") have been shown to help in diagnosing depression in this population. Increasing data show that treatment of depression in chronic illness is possible and improves both morbidity and mortality.

For patients and families facing mortality, existential and spiritual concerns are common. Progressive illness often raises questions of love, legacy, loss, and meaning. A physician's role is not to answer these questions or to provide reassurance, but rather to understand concerns of the patient and family, how they are coping, and what resources might help. Spirituality often is a source of comfort, and physicians can ascertain a patient's beliefs using a brief instrument such as the FICA Spiritual Assessment Tool (Table 3-2). A single screening question such as "Are you at peace?" may identify patients who are in spiritual distress and facilitate referrals to chaplains.

Is the Family Suffering?

Families, defined broadly as those individuals who care most for the patient, are an important source of support for most patients. Families provide informal caregiving, often at the expense of their own physical, economic, and psychological health. Good palliative care requires an understanding of how the family is coping and a search for ways to provide family members with the social or clinical resources they need to improve their well-being. Comprehensive and individually targeted interventions can reduce caregivers' burdens, although the absolute benefits are relatively small.

Because patients in palliative care often die, the palliative care team must address bereavement and postdeath family suffering. Good communication and informational brochures in an intensive care unit can decrease family members' adverse psychological outcomes after death. A letter of condolence or a follow-up phone call to the next of kin after a patient's death is respectful and offers the opportunity to clarify questions about the patient's care. Some family members suffer from complicated grief—a recently described syndrome associated with separation and traumatic distress, with symptoms persisting for more than 6 months. Primary care physicians, who have ongoing relationships with the loved one, and hospices, which provide bereavement services for a year after the patient's death, have the opportunity to assess whether the grief symptoms persist or worsen.

Is the Patient's Care Consistent with the Patient's Goals?

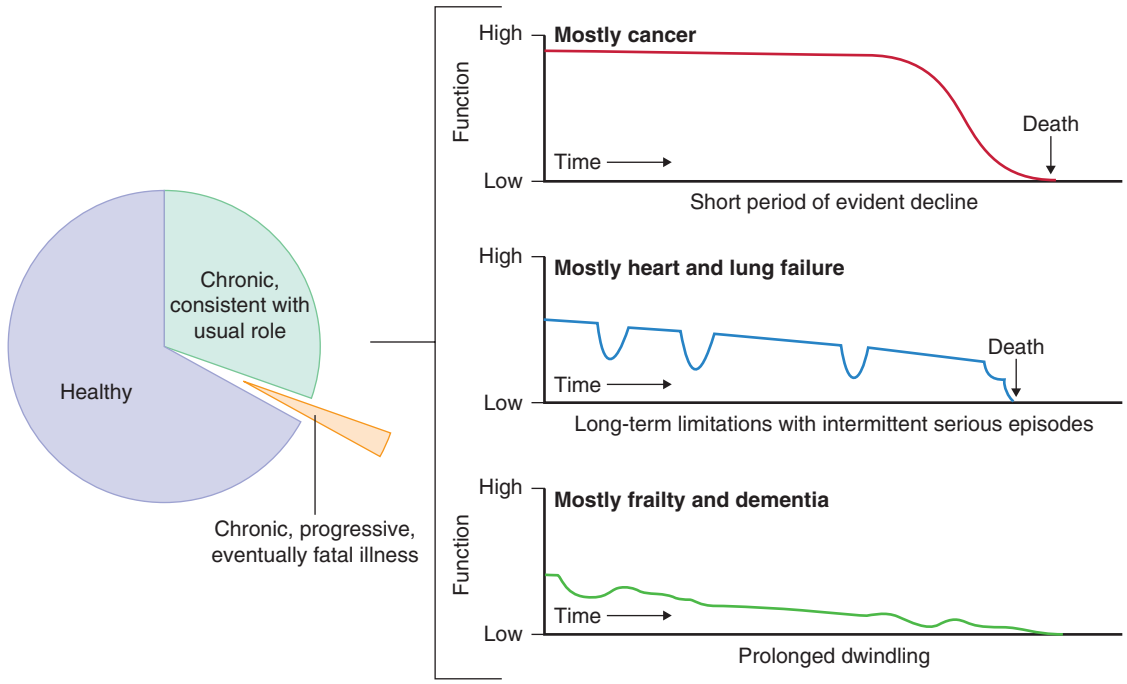
The sine qua non for palliative care is ensuring that the treatment plan is consistent with the patient's values. In one European cohort of elderly patients, most preferred longevity over quality of life, and half wanted resuscitation if necessary.[3] However, a large proportion of elderly, seriously ill patients are not focused on living as long as possible. Instead, they want to maintain a sense of control, relieve their symptoms, improve their quality of life, avoid being a burden on their families, and have a closer relationship with their loved ones.

Ensuring that treatment is consistent with a patient's goals requires good communication skills (Table 3-3). The approaches to giving bad news, discussing goals of care, and talking about forgoing life-sustaining treatment have similar structures (Table 3-4). First, the patient needs to understand the basic facts about the diagnosis, possible treatments, and prognosis. The communication skill that helps physicians communicate information is *Ask-Tell-Ask*—exploring what the patient knows or wants to know, then explaining or answering questions, and then providing an opportunity for the patient to ask more. In the hospital, where discontinuity of care is common and misunderstandings frequent, it is important to determine what the patient knows before providing information so as to keep everyone well coordinated. When giving bad news, knowing what the patient knows allows the physician to anticipate the patient's reaction. Finally, information must be titrated based on the patient's preferences. Although most patients want to hear everything about their disease, a minority do not. There is no foolproof way to ascertain what any patient wants to know other than by asking.

When giving patients information, it is important to give small pieces of information, not use jargon, and check the patient's understanding.[4] Giving information is like dosing a medication: one gives information, checks understanding, and then gives more information based on what the patient has heard.

After ensuring that the doctor and the patient have a shared understanding of the medical facts, the physician should engage in an open-ended conversation about the patient's goals as the disease progresses. This strategy requires that the patient be asked about both hopes and fears. One might ask: "What makes life worth living for you?" "If your time is limited, what are the things that are most important to achieve?" "What are your biggest fears or concerns?" "What would you consider to be a fate worse than death?" The clinician can use an understanding of these goals to make recommendations about which treatments to provide and which treatments would not be helpful. As a result, early palliative care can improve quality of life, mood, and even survival.

Physicians find talking about prognosis particularly difficult for two reasons: first, it is hard to foretell the future accurately; and second, they fear this information will "take away patients' hope." Thus, they often avoid talking to patients about these issues unless specifically asked. Although some patients do not want to hear prognostic information, for many patients, this



E-FIGURE 3-1. Different disease trajectories for different illnesses. Permission obtained from RAND Corporation © Lynn J. Perspectives on care at the close of life. Serving patients who may die soon and their families: the role of hospice and other services. *JAMA*. 2001;285:925-932.

TABLE 3-1 APPROACHES TO THE MANAGEMENT OF PHYSICAL AND PSYCHOLOGICAL SYMPTOMS

SYMPTOM	ASSESSMENT	TREATMENT
Pain	How severe is the symptom (as assessed with the use of validated instruments) and how does it interfere with the patient's life? What is the etiology of the pain? Is the pain assumed to be neuropathic or somatic? What has the patient used in the past (calculate previous days' equal analgesic dose)?	Prescribe medications to be administered on a standing or regular basis if pain is frequent. For mild pain: use acetaminophen or a nonsteroidal anti-inflammatory agent (see Table 30-3). For moderate pain: titrate short-acting opioids (see Table 30-4). For severe pain: rapidly titrate short-acting opioids until pain is relieved or intolerable side effects develop; start long-acting opiates once pain is controlled. Rescue doses: prescribe immediate-release opioids—10% of the 24-hour total opiate every hour (orally) or every 30 minutes (parenterally) as needed. Concomitant analgesics (e.g., corticosteroids, anticonvulsants, tricyclic antidepressants, and bisphosphonates) should be used when applicable (particularly for neuropathic pain). Consider alternative medicine and interventional treatments for pain.
Constipation	Is the patient taking opioids? Does the patient have a fecal impaction?	Prescribe laxatives for all patients on opiates. If ineffective, add drugs from multiple classes (e.g., stimulant, osmotic laxatives, and enemas). Prescribe methylnaltrexone if still constipated.
Shortness of breath	Ask the patient to assess the severity of the shortness of breath. Does the symptom have reversible causes?	Prescribe oxygen to treat hypoxia-induced dyspnea, but *not* if the patient is not hypoxic. Opioids relieve breathlessness without measurable reductions in respiratory rate or oxygen saturation; effective doses are often lower than those used to treat pain. Aerosolized opiates do not work. Fans or cool air may work through a branch of the trigeminal nerve. Consider anxiolytics (e.g., low-dose benzodiazepines) and use reassurance, relaxation, distraction, and massage therapy.
Fatigue	Is the patient too tired to do activities of daily living? Is the fatigue secondary to depression? Is a disease process causing the symptom or is it secondary to reversible causes?	Provide cognitive education about conserving energy use. Treat underlying conditions appropriately.
Nausea	Which mechanism is causing the symptom (e.g., stimulation of the chemoreceptor trigger zone, gastric stimulation, delayed gastric emptying or "squashed stomach" syndrome, bowel obstruction, intracranial processes, or vestibular vertigo)? Is the patient constipated?	Prescribe an agent directed at the underlying cause (Chapter 132). If persistent, give antiemetic around the clock. Multiple agents directed at various receptors or mechanisms may be required.
Anorexia and cachexia	Is a disease process causing the symptom, or is it secondary to other symptoms (e.g., nausea and constipation) that can be treated? Is the patient troubled by the symptom or is the family worried about what not eating means?	A nutritionist may help find foods that are more appetizing (Chapter 213). Provide counseling about the prognostic implications of anorexia (Chapter 219).
Delirium	Is the confusion acute, over hours to days? Does consciousness wax and wane? Are there behavioral disturbances, marked by a reduced clarity in the patient's awareness of the environment, e.g., a problem of attention? Does the patient have disorganized thinking? Does the patient have an altered level of consciousness—either agitated or drowsy? Is there a reversible reason for the delirium? **D: D**rugs (opioids, anticholinergics, sedatives, benzodiazepines, steroids, chemotherapies and immunotherapies, some antibiotics) **E: E**yes and **E**ars (poor vision and hearing, isolation) **L: L**ow-flow states (hypoxia, myocardial infarction, congestive heart failure, chronic obstructive pulmonary disease, shock) **I: I**nfections **R: R**etention (urine/stool), **R**estraints **I: I**ntracranial (central nervous system metastases, seizures, subdural, cerebrovascular accident, hypertensive encephalopathy) **U: U**nderhydration, **U**ndernutrition, **U**ndersleep **M: M**etabolic disorders (sodium, glucose, thyroid, hepatic, deficiencies of vitamin B_{12}, folate, niacin, and thiamine) and toxic (lead, manganese, mercury, alcohol)	Identify underlying causes and manage symptoms (Chapter 28). Recommend behavioral therapies, including avoidance of excess stimulation, frequent reorientation, and reassurance. Ensure presence of family caregivers and explain delirium to them. Prescribe haloperidol, risperidone, or olanzapine.
Depression	Have you felt down, depressed, or hopeless most of the time during the past 2 weeks? Have you found that little brings you pleasure or joy during the past 2 weeks? (Somatic symptoms are not reliable indicators of depression in this population.)	Recommend supportive psychotherapy, cognitive approaches, behavioral techniques, pharmacologic therapies (see Table 397-5), or a combination of these interventions; prescribe psychostimulants for rapid treatment of symptoms (within days) or selective serotonin reuptake inhibitors, which may require 3 to 4 weeks to take effect; tricyclic antidepressants are relatively contraindicated because of their side effects.
Anxiety (applicable also for family members)	Does the patient exhibit restlessness, agitation, insomnia, hyperventilation, tachycardia, or excessive worry? Is the patient depressed? Is there a spiritual or existential concern underlying the anxiety?	Recommend supportive counseling and consider prescribing benzodiazepines.
Spiritual distress	Are you at peace?	Inquire about spiritual support.

Modified from Morrison RS, Meier DE. Palliative care. *N Engl J Med.* 2004;350:2582-2590.

information helps them plan their lives. Patients who are told that their disease is generally terminal are more likely to spend a longer period of time in hospice and to avoid aggressive technology at the end of life, without adverse psychological consequences. Furthermore, their families usually have fewer postdeath adverse psychological outcomes.

Given that one cannot guess how much information to provide, a physician can start these conversations by asking, "Are you the kind of person who wants to hear about what might happen in the future with your illness or would you rather take it day by day?" If the patient requests the latter, the physician can follow up by asking if there is someone else with whom he or she can talk about the prognosis. Second, before giving prognostic information, it is useful to inquire about the patient's concerns in order to provide information in the most useful manner. Finally, it is appropriate when discussing prognostic information to acknowledge uncertainty: "The course of this cancer can be quite unpredictable, and physicians don't have a crystal ball. I think you should be aware of the possibility that your health may

Brief Pain Inventory (Short Form)

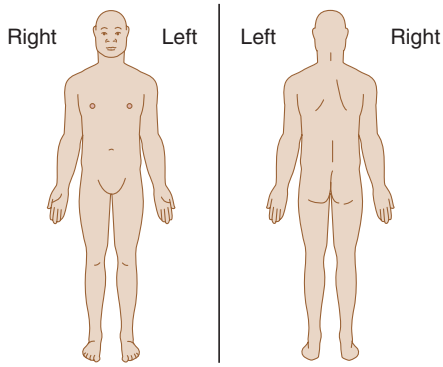
Date: ___/___/___ Time: ____

Name: _____ (Last) _____ (First) _____ (Middle Initial)

1. Throughout our lives, most of us have had pain from time to time (such as minor headaches, sprains, and toothaches). Have you had pain other than these everyday kinds of pain today?

1. Yes 2. No

2. On the diagram, shade in the areas where you feel pain. Put an X on the area that hurts the most.



3. Please rate your pain by circling the one number that best describes your pain at its worst in the last 24 hours.

0	1	2	3	4	5	6	7	8	9	10
No pain										Pain as bad as you can imagine

4. Please rate your pain by circling the one number that best describes your pain at its least in the last 24 hours.

0	1	2	3	4	5	6	7	8	9	10
No pain										Pain as bad as you can imagine

5. Please rate your pain by circling the one number that best describes your pain on the average.

0	1	2	3	4	5	6	7	8	9	10
No pain										Pain as bad as you can imagine

6. Please rate your pain by circling the one number that tells how much pain you have right now.

0	1	2	3	4	5	6	7	8	9	10
No pain										Pain as bad as you can imagine

FIGURE 3-1. Brief Pain Inventory (short form).

7. What treatments or medications are you receiving for your pain?

8. In the last 24 hours, how much relief have pain treatments or medications provided? Please circle the one percentage that most shows how much relief you have received.

0%	10%	20%	30%	40%	50%	60%	70%	80%	90%	100%
No pain										Complete relief

9. Circle one number that describes how, during the past 24 hours, pain has interfered with your:

A. General Activity

0	1	2	3	4	5	6	7	8	9	10
Does not interfere										Completely interferes

B. Mood

0	1	2	3	4	5	6	7	8	9	10
Does not interfere										Completely interferes

C. Walking Ability

0	1	2	3	4	5	6	7	8	9	10
Does not interfere										Completely interferes

D. Normal Work (includes both work outside the home and housework)

0	1	2	3	4	5	6	7	8	9	10
Does not interfere										Completely interferes

Does not interfere										Completely interferes

FIGURE 3-1, cont'd.

deteriorate quickly, and you should plan accordingly. We probably are dealing with weeks to months, although some patients do better, and some do worse. Over time, the course may become clearer, and if you wish, I may be able to be a little more precise about what we are facing."

The physician must discuss these topics in an empathic way. Palliative care conversations are as much about emotions as facts.[5] Talking about disease progression or death may elicit negative emotions such as anxiety, sadness, or frustration. These emotions decrease a patient's quality of life and interfere with the ability to hear factual information. Empathic responses strengthen the patient-physician relationship, increase the patient's satisfaction, and make the patient more likely to disclose other concerns. The first step is recognizing when the patient is expressing emotions. Once the physician recognizes the emotion being expressed, he or she can respond empathically.

It is also important for physicians to recognize their own emotional reactions to these conversations. The physician's emotional reactions color impressions of the patient's prognosis, thereby making it hard to listen to the patient, and may influence the physician to hedge bad news. The physician should become aware of her or his own emotional reactions to ensure that the conversation focuses on the patient rather than the health care provider's needs.

In addition to good communication skills, palliative care requires a basic knowledge of medical ethics and the law. For example, patients have the moral and legal right to refuse any treatment, even if refusal results in their death. There is no legal difference between withholding and withdrawing life-sustaining treatment. When confronted with areas of ambiguity, the physician should know how to obtain either a palliative care or ethics consultation.

TABLE 3-2 FICA SPIRITUAL ASSESSMENT TOOL

F—What is your **faith**/religion? Do you consider yourself a religious or spiritual person? What do you believe in that gives meaning/importance to life?

I—**Importance** and **influence** of faith. Is your faith/religion important to you? How do your beliefs influence how you take care of yourself? What are your most important hopes? What role do your beliefs play in regaining your health? What makes life most worth living for you? How might your disease affect this?

C—Are you part of a religious or spiritual **community**? Is this of support to you, and how? Is there a person you really love or is very important to you? How is your family handling your illness? What are their reactions/expectations?

A—How would you like me to **address** these issues in your health care? What might be left undone if you were to die today? Given the severity or chronicity of your illness, what is most important for you to achieve? Would you like me to talk to someone about religious/spiritual matters?

From Puchalski C, Romer A. Taking a spiritual history. *J Palliat Med.* 2000;3:129-137.

TABLE 3-3 CORE COMMUNICATION SKILLS

RECOMMENDED SKILL	EXAMPLE
A. IDENTIFYING CONCERNS AND RECOGNIZING CUES	
Elicit Concerns	
Open-ended questions	"Is there anything you wanted to talk to me about today?"
Active listening	Allowing patient to speak without interruption; allowing pauses to encourage patient to speak
Recognize Cues	
Informational concerns	Patient: "I'm not sure about the treatment options"
Emotional concerns	Patient: "I'm worried about that"
B. RESPONDING TO INFORMATIONAL CONCERNS	
"Ask-tell-ask"	Topic: communicating information about cancer stage
Ask	"Have any of the other doctors talked about what stage this cancer is?"
Tell	"That's right, this is a stage IV cancer, which is also called metastatic cancer…"
Ask	"Do you have questions about the staging?"
C. RESPONDING TO EMOTIONAL CONCERNS	
Nonverbal Empathy: S-O-L-E-R	
S	Face the patient **S**quarely
O	Adopt an **O**pen body posture
L	**L**ean toward the patient
E	Use **E**ye contact
R	Maintain a **R**elaxed body posture
Verbal Empathy: N-U-R-S-E	
N	**N**ame the emotion: "You seem worried"
U	**U**nderstand the emotion: "I see why you are concerned about this"
R	**R**espect the emotion: "You have shown a lot of strength"
S	**S**upport the patient: "I want you to know that I will still be your doctor whether you have chemotherapy or not"
E	**E**xplore the emotion: "Tell me more about what is worrying you"

From Back AL, Arnold RM, Tulsky JA. *Discussing Prognosis.* Alexandria, VA: American Society of Clinical Oncology; 2008.

During the past 10 years, there has been a societal push to encourage patients to designate health care proxies and to create advance care planning documents, typified by the use of living wills. These documents are meant to protect patients against unwanted treatments and to ensure that as they are dying, their wishes are followed.[6] Unfortunately, there are few empirical data showing that these documents actually change practice. Still, discussions of the documents with health professionals and family members generally provoke important conversations about end-of-life care decisions and may help families confronted with difficult situations know they are respecting their loved one's wishes.

TABLE 3-4 DISCUSSING PALLIATIVE CARE

GENERAL APPROACH

- Plan what to say. Create the right setting, allow adequate time, and determine who else should be present at the meeting.
- Listen carefully. Be prepared for strong emotions, respond empathetically, encourage description of feelings, and allow time for silence and response.

ESTABLISHING GOALS OF MEDICAL CARE

- Determine what the patient knows. Clarify any uncertainties or misconceptions.
- Understand what the patient is hoping to accomplish as well as any fears and worries.
- Repeat the goals back to the patient to make sure they are heard.
- Suggest treatments to meet these goals and clarify what will not be done because it will not help achieve the goals. Focus on the goals that you think you can achieve. Plan follow-up, review and revise plan as needed.

COMMUNICATING BAD NEWS

- Determine what the patient knows, wants to know, and can comprehend.
- Share information, recognizing that people handle information in different ways.
- Avoid jargon, pause frequently, check for understanding, and use silence.
- Recognize and support the patient's emotional reaction.
- Assess the patient's safety.
- Agree to a plan that enlists potential sources of support.

WITHDRAWING TREATMENT

- Discuss the context of the current discussion and what has changed to precipitate it.
- Review prior treatment goals and reassess their virtues.
- Discuss alternative treatments based on the new goals.
- Document a plan for forgoing treatment and share with the patient, the patient's family, and the health care team.

Adapted from Morrison RS, Meier DE. Clinical practice. Palliative care. *N Engl J Med.* 2004;350:2582-2590.

Is the Patient Going to Die in the Location of Choice?

Most patients say that they want to die at home. Unfortunately, most patients die in institutions—either hospitals or nursing homes. Burdensome transitions decrease quality in end-of-life care. Good palliative care requires establishing a regular system of communication to minimize transitional errors. A social worker who knows about community resources is important in the development of a dispositional plan that respects the patient's goals.

Hospice programs are an important way to allow patients to die at home. In the United States, *hospice* refers to a specific, government-regulated form of end-of-life care, available under Medicare since 1982 but subsequently adopted by Medicaid and many other third-party insurers. Hospice care typically is given at home, a nursing home, or specialized acute care unit. Care is provided by an interdisciplinary team, which usually includes a physician, nurse, social worker, chaplain, volunteers, bereavement coordinator, and home health aides, all of whom collaborate with the primary care physician, patient, and family. Bereavement services are offered to the family for a year after the death.

Hospices are paid on a per diem rate and are required to cover all the costs related to the patient's life-limiting illness. Because of this and the fact that their focus is on comfort rather than life prolongation, many hospices will not cover expensive treatments such as inotropic agents in heart failure or chemotherapy in cancer, even if they have a palliative effect. Many hospices are experimenting with different service models in an attempt to enroll patients earlier in the course of their illness and increase access to their services.

REVIEW QUESTIONS

1. A 75-year-old man with lung cancer is admitted to the hospital with severe shortness of breath. Work-up reveals no other cause of his shortness of breath other than lymphogenic spread of his cancer. His oxygen saturation is 94%. Which of the following treatments should be instituted for his dyspnea?

A. Morphine
B. Benzodiazepines
C. Oxygen
D. A and C
E. All the above

Answer: A In randomized controlled data, opioids have been shown to decrease dyspnea both in lung cancer patients and in patients with COPD. Oxygen is helpful only if the patient has hypoxia. Benzodiazepines have not been shown to decrease breathlessness.

2. Which of the following is NOT required for a patient to be in hospice?

A. The patient must be DNR.
B. The patient must have a life-limiting illness, which is likely to cause her death in 6 months.
C. The patient wishes to focus on quality of life rather than longevity of life.
D. If the patient lives at home, she must have a primary caregiver.

Answer: A The patient does not have to be DNR to be in hospice. The others are requirements of hospice.

3. Which of the following is true of depression in life-limiting illnesses?

A. It is a normal reaction when people have a life-limiting illness, and it should not be treated.
B. It cannot be improved because the treatments take too long to work in patients with serious illness.
C. Treatment of depression decreases both morbidity and mortality.
D. It requires a psychiatric consult because treatment is very complicated.

Answer: C Data show that the treatment of depression improves both quality of life and mortality.

4. Which of the following is true?

A. Telling patients that they have a terminal illness will result in their losing hope.
B. Telling patients they have a terminal illness has no impact on their desire for future treatment.
C. Telling patients that they have terminal illnesses is associated with their choosing hospice more frequently.
D. Patients have clearly stated that they do not want to be told that they have a terminal illness.

Answer: C Data suggest that telling patients that they have a life-limiting illness is associated with a lower likelihood of choosing aggressive care at the end of life and is not associated with poorer psychiatric outcomes.

CULTURAL CONTEXT OF MEDICINE

VICTORIA M. TAYLOR

The 2010 U.S. Census counted about 39 million blacks or African Americans (13% of the population), nearly 15 million Asian Americans (5% of the population), about 3 million American Indians and Alaska Natives, and more than 500,000 Native Hawaiians and other Pacific Islanders. It also counted more than 50 million individuals of Hispanic or Latino origin (16% of the population). Approximately 40 million Americans (13% of the population) were foreign born. One in 2 immigrants to the United States have limited English proficiency (i.e., they do not speak English very well or fluently), and 1 in 10 immigrants do not speak English at all (Fig. 4-1).

During the past two decades, a large body of literature has documented substantial disparities in health status. Although some of these disparities are based on socioeconomic status, many are based on race, ethnicity, or other characteristics. Black men have a substantially higher age-adjusted incidence of prostate cancer than do white men (236 per 100,000 versus 147 per 100,000). American Indians/Alaska Natives are more than twice as likely as non-Latino whites of a similar age to have diabetes. More than half of the Americans who are living with chronic hepatitis B infection are Asians or Pacific Islanders. Lesbian, gay, bisexual, and transgender individuals have higher rates of suicidal behavior compared with heterosexual individuals. A major goal of Healthy People 2020 is to eliminate health disparities for preventable and treatable conditions such as cancer, diabetes, and human immunodeficiency virus infection.

Culture can be defined as a shared system of values, beliefs, and patterns of behavior, and it is not simply defined by race and ethnicity. Culture can also be shaped by factors such as country and region of origin, acculturation, language, religion, and sexual orientation. For instance, the black population of the northeastern United States includes individuals who moved from southern states decades ago as well as recent immigrants from Ethiopia. As the United States population becomes increasingly diverse and as pronounced differences in health status continue to be documented, consideration of the cultural context of medicine is becoming a national priority.

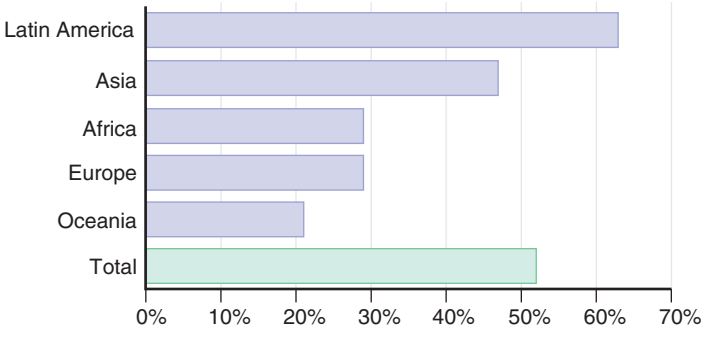

FIGURE 4-1. Proportion of immigrants aged 5 years and older with limited English proficiency by region of origin. (From Grieco EM, Acosta YD, de la Cruz P, et al. The foreign-born population in the United States: 2010. Washington DC: U.S. Department of Commerce; 2012.)

DISPARITIES IN HEALTH CARE ACCESS AND QUALITY

Components of health care access include the ability to get into the health care system as well as to obtain appropriate care once in the system. The availability of health care providers who meet an individual patient's needs is another key component of access to care. Quality care is based on scientific evidence (i.e., is effective), avoids injury to the patient (i.e., is safe), minimizes harmful delays (i.e., is timely), is responsive to the individual patient's needs (i.e., is patient centered), promotes communication among providers (i.e., is coordinated), does not vary because of personal characteristics (i.e., is equitable), and avoids waste (i.e., is efficient).

Access to Health Care

Racial and ethnic minority groups, particularly immigrants, disproportionately have problems accessing health care. Before the implementation of the Affordable Care Act, the proportions of Latinos and Native Americans/Alaska Natives who lacked health insurance was more than twice the proportion among non-Latino whites, and less than two thirds of Americans with limited English proficiency were insured. About 1 in 3 Korean American and Vietnamese American adults had no regular source of medical care compared with about 1 in 10 non-Latino white adults.

Blacks and Latinos are far less likely than are whites and Asians to have access to physicians of their own race and ethnicity. This imbalance is important because racial concordance between physicians and patients can improve the processes of care. For example, patients with race-concordant physicians are more likely to use needed health services, are less likely to postpone or delay seeking care, and are more satisfied with their care than are patients in race-discordant relationships. Whether these differences translate into different health outcomes, however, is less clear.[1]

Quality of Health Care

National surveys confirm population-level disparities in the quality of preventive care. Recent immigrants have far lower levels of interval screening for breast, cervical, and colorectal cancer than do individuals who were born in the United States (Fig. 4-2). The proportion of Native Hawaiians and other Pacific Islanders whose serum cholesterol levels are measured at least once every 5 years is significantly lower than among whites. In 2011, only 40% of Asians aged 65 years and older had ever received the pneumococcal vaccine compared with 67% of non-Latino whites.

Racial and ethnic disparities have been documented for a number of specific clinical situations. For example, Latino women with breast cancer are less likely to receive radiation therapy within a year of breast-conserving surgery than are white women, Native Americans and Alaska Natives are less likely than whites to receive recommended care such as initial antibiotics within 6 hours of hospital arrival, and blacks with end-stage renal disease

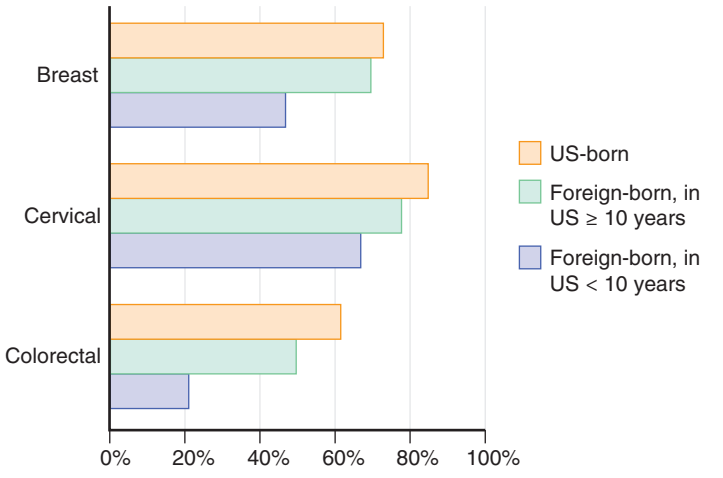

FIGURE 4-2. Adherence to cancer screening guidelines by immigration status. Breast = mammography during last 2 years among women aged 50 to 74 years. Cervical = Papanicolaou test during last 3 years among women aged 21 to 65 years. Colorectal = among individuals aged 50 to 75 years, fecal occult blood test last year; sigmoidoscopy last 5 years and fecal occult blood test last 3 years; or colonoscopy last 10 years. (From Centers for Disease Control and Prevention. Cancer screening—United States, 2010. *MMWR Morb Mortal Wkly Rep.* 2012; 61:41-45.)

are less likely to be entered to a transplant list than are whites. Moreover, disparities in the quality of care are found even when variations in insurance status, income, and comorbid conditions are taken into account.

Disparities in health care quality exist even in systems that are generally believed to provide equal access.[2] For example, in the Veterans Affairs Health System, disparities between blacks and whites have been documented for blood pressure control among patients with hypertension, cholesterol control among patients with coronary heart disease, and glucose control among patients with diabetes. Moreover, these disparities persist even after adjusting for location and socioeconomic status. Similar disparities have been documented in Medicare managed care programs between elderly blacks and whites with diabetes and cardiovascular disorders.

CULTURAL COMPETENCE IN HEALTH CARE

Health disparities can be reduced or perhaps even eliminated by maintaining culturally competent health care systems. Cultural competence may be defined as a set of congruent attitudes, behaviors, and policies that come together both among professionals and within systems to enable effective work in cross-cultural situations (Fig. 4-3). Ongoing efforts to improve cultural competence in the health care system target organizational, structural, and clinical barriers. These initiatives aim to close gaps in health status, to decrease differences in the quality of care, to enhance patients' satisfaction, and to increase patients' trust.

Organizational Barriers and Interventions

Diversity among health care professionals is associated with better access to care for disadvantaged populations. Black and Latino physicians are more likely than their white colleagues to work in medically underserved communities and to have a better understanding of barriers to health care. Because less than 10% of practicing physicians are black or Latino, and only about 15% of medical school students are from one of these groups, many U.S. medical schools have implemented comprehensive programs to infuse diversity among their students, resident physicians, and faculty.

About two thirds of the patients who receive care at federally funded community health centers in medically underserved areas are members of racial and ethnic minority groups. In these health centers, patients are three times more likely to have limited proficiency in English compared with the general population. The community health center model has proved effective not only in increasing access to care but also in improving continuity of care and health outcomes. For example, medically underserved communities with community health centers have fewer preventable hospitalizations and uninsured emergency department visits than do similar communities without health centers. Compared with national rates, community health centers report minimal racial and ethnic disparities in clinical outcomes such as the control of diabetes and hypertension.[3]

Structural Barriers and Interventions

Accumulating evidence suggests that trained professional interpreters can improve the clinical care received by individuals with limited English proficiency. However, interpreter services often remain ad hoc, with family members and untrained nonclinical employees acting as interpreters.[4] Use of ad hoc services has potentially negative clinical consequences, including breach of the patient's confidentiality and inaccurate communication. One major obstacle to the implementation of professional interpreter programs is a lack of reimbursement; Medicare and most private insurers do not pay for interpretation and related services, and most states do not pay for interpretation under Medicaid.

Assistance with navigation represents a promising model to enable racial and ethnic minority patients to move through the health system effectively and to be actively involved in decision making about their medical care.[5] Guides may be nurses, social workers, or volunteers who are familiar with the health care system. They help patients and their families navigate the treatment process, steering them around obstacles that may limit their access to quality care, choice of doctors, and access to treatment options. For example, an American Cancer Society navigation program is effective in reducing the time to diagnostic resolution after abnormal cancer screening tests in medically underserved patients.

Another option for closing the gap in health care among various minority populations is community health workers.[6] In general, community health workers live locally and share the language and culture of the patients being served. Lay community health workers provide cultural mediation between communities and the health care system; culturally appropriate and accessible health education and information; help in obtaining needed medical services, informal counseling, and social support; and advocacy within the health care system. The effectiveness of community health workers is documented by a study in which Mexican American women randomized to

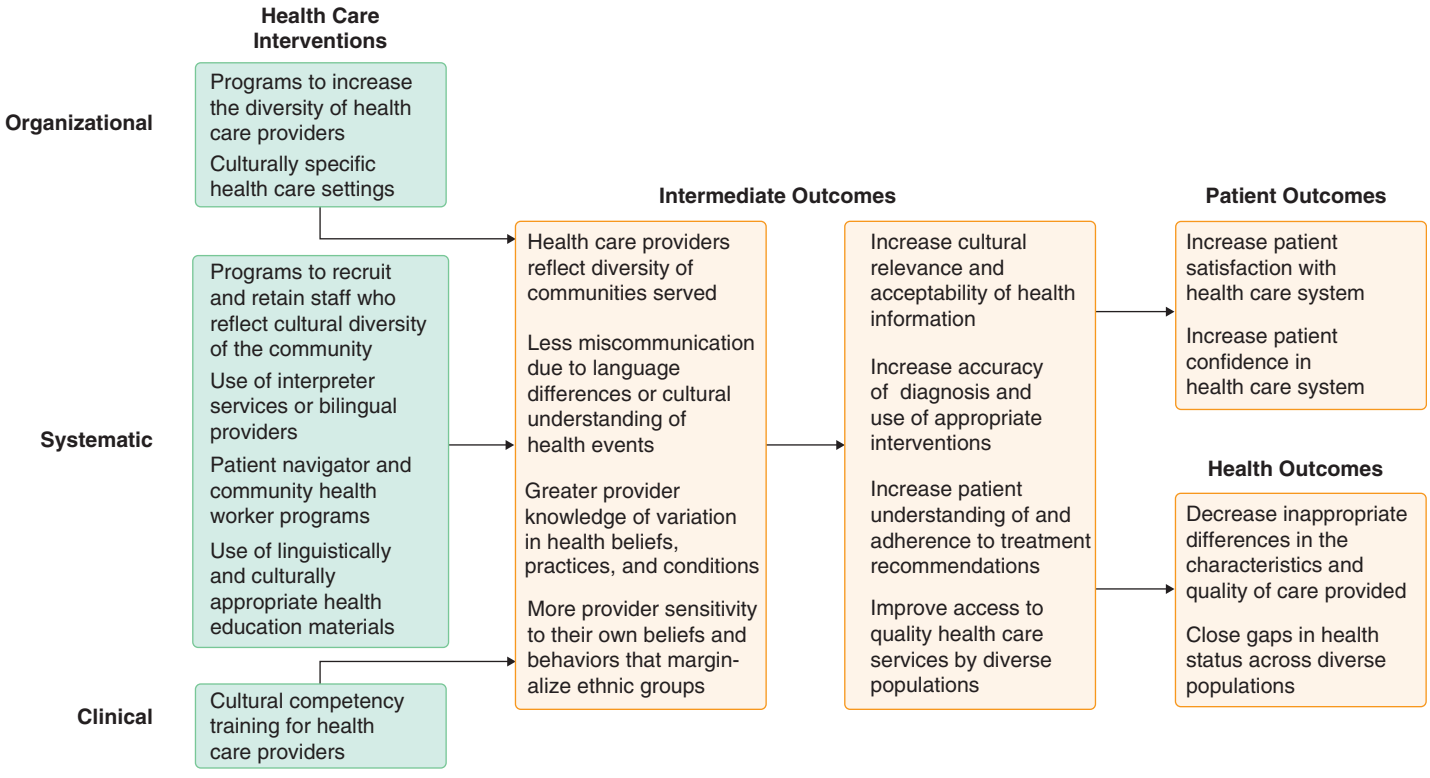

FIGURE 4-3. Analytic framework for evaluating the effectiveness of health care interventions to increase cultural competence. (From Anderson LM, Scrimshaw SC, Fullilove MT, et al., for the Task Force on Community Preventive Services. Culturally competent healthcare systems: a systemic review. *Am J Prev Med.* 2003; 24[suppl]:68-79.)

receive health worker education were significantly more likely to obtain Papanicolaou tests than were women randomized to receive usual care.[A] The largest formal system of community health workers is the Indian Health Service, which currently has about 1400 community health representatives.

Clinical Barriers and Interventions

Patients who are members of racial and ethnic minority groups often understand health and disease (i.e., explanatory model) differently than the general population. For example, many Vietnamese people believe that disease is caused by an imbalance of the humoral forces of yin and yang. When ill, they commonly use Chinese herbal medicine as well as indigenous folk practices known as Southern medicine in an effort to restore the balance of humoral forces. In addition, Vietnamese patients may think that Western medicine is too strong and will upset the internal balance. Consequently, a hypertensive Vietnamese patient may, for example, use Chinese herbal medicines instead of prescribed antihypertensive medication. Alternatively, the patient may take a lower dose of medication than prescribed by his or her physician.

Cultural competency training for health care providers generally includes teaching cross-cultural knowledge and communication skills, while avoiding stereotypes.[7] Examples include the effect of prejudice on gays and lesbians and how this prejudice shapes their interactions with the health care system, and common spiritual practices that might interfere with prescribed therapies (such as Ramadan fasting practices, when observed by diabetic Muslim patients). Communication skills that can be addressed in cultural competence training include approaches to eliciting patients' explanatory models and use of traditional treatments, as well as methods for negotiating different styles of communication and levels of family participation in decision-making. Cultural competency training improves the attitudes and skills of health professionals as well as patient satisfaction, but there is less evidence that it improves clinical outcomes.[A]

SUMMARY

Individual clinical practices should regularly assess their current organizational climate, policies, and training related to diversity. Practices can address health disparities by hiring clinical and office staff who are representative of the communities they serve, by routinely using professional interpreters during clinical encounters with patients who have limited proficiency with English, by offering cultural competency education and training to physicians and staff, and by providing educational and informational materials that are culturally and linguistically appropriate for their patient populations.[8]

National and state efforts to improve cultural competence in health care, whether used alone or in conjunction with socioeconomic initiatives, are likely to play a significant role in reducing health disparities across population subgroups. An important goal of the Affordable Care Act is to reduce health disparities by expanding health insurance coverage, addressing diversity in the health care workforce, increasing the capacity of community health centers, and promoting the use of patient navigators and community health workers.

REVIEW QUESTIONS

1. What percentage of immigrants to the United States have limited English proficiency?

A. 20%
B. 30%
C. 40%
D. 50%
E. 60%

Answer: D The 2010 Census found that one in two immigrants have limited English proficiency. (Grieco EM, Acosta YD, de la Cruz GP, et al. The foreign born population in the United States: 2010. Washington, DC: U.S. Department of Commerce, 2012.)

2. A 19-year-old Vietnamese man presents for a routine physical examination. He is a recent immigrant, has no symptoms or significant medical history, and has not previously had a physical examination or any blood testing in the United States. Which of the following blood tests should you perform?

A. HIV
B. Hepatitis B
C. Glucose
D. Cholesterol
E. All of the above

Answer: B More than half of the Americans who have chronic hepatitis B infection are Asians or Pacific Islanders. Therefore, all immigrants from Asia should be tested for hepatitis B. (Pollack H, Wang S, Wyatt Le, et al. A comprehensive screening and treatment model for reducing disparities in hepatitis B. *Health Aff.* 2011;30:1974-1983.)

3. Which of the following statements about health insurance is incorrect?

A. Whites are more likely to have insurance than American Indians/Alaska Natives.
B. Latinos are less likely to have insurance than non-Latino whites.
C. Gay/lesbian/homosexual individuals are less likely to have insurance than heterosexual individuals.
D. Citizens are more likely to have insurance than noncitizens.
E. Individuals who are proficient in English are more likely to have insurance than individuals who are not.

Answer: C The California Health Interview Survey provides information about health insurance coverage among population subgroups and shows differences by race/ethnicity, citizenship status, and level of English proficiency but not by sexual orientation. (University of California Los Angeles. Ask CHIS 2009, http://www.chis.ucla.edu. Accessed March 22, 2014.)

4. Which of the following are core community health worker functions?

A. Cultural mediation
B. Health education
C. Informal counseling
D. Social support
E. All of the above

Answer: E Cultural mediation, health education, informal counseling, and social support are all core community health worker functions. (Brownstein JN, Hirsch GR, Rosenthal EL, Rush CH. Community health workers 101 for primary care providers and other stakeholders in health care systems. *J Ambul Care Manage.* 2011;34:210-220.)

5. Your practice has recently started seeing a large number of Hispanic immigrant patients with limited English proficiency. You have decided to make some changes to your practice to accommodate the specific needs of these patients. Which of the following approaches are appropriate?

A. Hire Hispanic staff
B. Ask limited English proficiency patients to bring a family member with them to provide
C. Medical interpretation
D. Provide cultural competency training to providers
E. A and C
F. All of the above

Answer: D Clinical practices can address health disparities in multiple ways, including by hiring staff who are representative of the practice population, providing professional interpreter services, offering cultural competency training to providers, and providing linguistically appropriate patient education materials. Family members should not be asked to provide medical interpretation. (Washington DL, Bowles J, Saha S. Transforming clinical practice to eliminate racial-ethnic disparities in healthcare. *J Gen Intern Med.* 2008;23:685-691.)

5

SOCIOECONOMIC ISSUES IN MEDICINE

STEVEN A. SCHROEDER

All nations—rich and poor—struggle with how to improve the health of the public, obtain the most value from medical services, and restrain rising health care expenditures. Many developed countries also wrestle with the paradox that their citizens have never been so healthy or so unhappy with their medical care. Despite the reality that only about 10% of premature deaths result from inadequate medical care, the bulk of professional and political attention focuses on how to obtain and pay for state-of-the-art medical care. By comparison, 40% of premature deaths stem from unhealthy behaviors—including smoking (about 44%; Chapter 32), excessive or unwise drinking (about 11%; Chapter 33), obesity and insufficient physical activity (about 15% but estimated to rise substantially in the years to come; Chapters 16 and 220), illicit drug use (about 2%; Chapter 34), and imprudent sexual behavior (about 3%; Chapter 285). Genetics (Chapter 40) account for an additional 30%; social factors—discussed next—account for 15%, and environmental factors (Chapter 19) account for 5%. Of the major behavioral causes of premature deaths, tobacco use (Chapter 32) is by far the most important, although recent increases in obesity (Chapter 220) and physical inactivity (Chapter 16) are also alarming. Health is influenced by genetic predisposition, behavioral patterns, environmental exposures, social circumstances, and health care.

SOCIAL STATUS INFLUENCES HEALTH

Socioeconomic status, or class, is a composite of many different factors, including income, net wealth, education, occupation, and neighborhood. In general, people in lower classes are less healthy and die earlier than people at higher socioeconomic levels, a pattern that holds true in a stepwise fashion from the poorest to the richest. In the United States, the association between health and class is usually discussed in terms of racial and ethnic disparities; but in fact, race and class are independently associated with health status, and it can be argued that class is the more important factor. For example, U.S. racial disparities in the prevalence of adult smoking are relatively small among whites, blacks, and Hispanic Americans, whereas there are huge differences among smoking rates by educational level (Fig. 5-1).[1] U.S. physicians have reduced their smoking prevalence to a record low of only 1%. Although both smoking rates and the numbers of cigarettes smoked by those who continue to smoke are gradually declining (Fig. 5-2), more than 43 million Americans and millions more elsewhere continue to smoke.[2] Because people of higher socioeconomic status adopt health-promoting behaviors at a faster rate than people of lower socioeconomic status, overall population health can increase while health disparities also widen (Fig. 5-3).

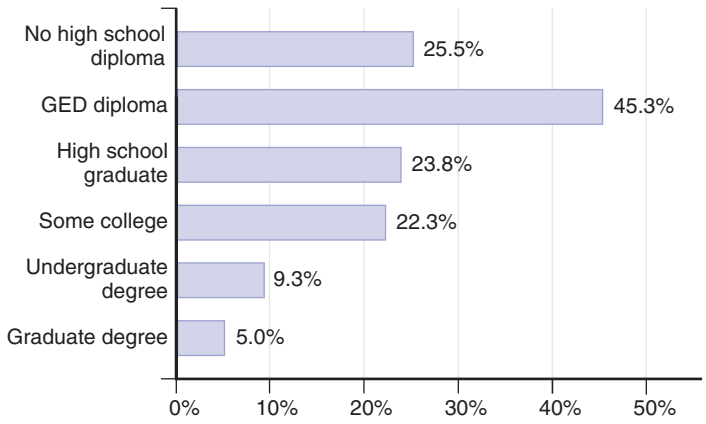

FIGURE 5-1. Prevalence of adult smoking, by education, United States, 2011. GED = General Education Development. (From Centers for Disease Control and Prevention. Current cigarette smoking among adults: United States, 2011. *MMWR Morb Mortal Wkly Rep.* 2012;61:889-894.)

In part, the relationship between class and health is mediated by higher rates of unhealthy behaviors among the poor, such as the inverse relationship between educational attainment and cigarette smoking, but unhealthy behaviors do not fully explain the poor health of those in the lower socioeconomic classes. Even when such behaviors are held constant, people in lower socioeconomic classes are much more likely to die prematurely than are people of higher classes. Of interest is that first-generation immigrants to the United States appear to be more protected from the adverse health consequences of low socioeconomic status than are subsequent generations.

It is unclear which of the components of class—education, wealth (either absolute wealth or the extent of the gap between rich and poor), occupation, or neighborhood—makes the greatest impact on a person's health. Most likely, it is a combination of all of them. For example, the constant stress of a lower class existence—lack of control over one's life circumstances, social isolation, and the anxiety derived from the feeling of having low status—is linked to poor health. This stress may trigger a variety of neuroendocrinologic responses that are useful for short-term adaptation but bring long-term adverse health consequences.

What can clinicians do with this knowledge? Clearly, it is difficult to write prescriptions for more income, a better education, good neighborhoods, or high-paying jobs. Physicians can, however, encourage healthy behavior. At key times of transition, such as during discharge planning for hospitalized patients, clinicians should be attentive to social circumstances. For patients who are likely to be socially isolated, clinicians should encourage or arrange interactions with family, neighbors, religious organizations, or community agencies to improve the likelihood of optimal outcomes. Access points to vital social services, such as child care, disability insurance, and food supplementation, can be provided in clinical settings.[3] In addition, physicians should seek to identify and eliminate any aspects of racism in health care institutions (Chapter 4). Finally, in their role as social advocates, physicians can promote such goals as safe neighborhoods, improved schools, and access to quality health care.

ECONOMIC ISSUES IN MEDICAL CARE

Medical care today is on a collision course. On the one hand, an ever-expanding science base continuously generates new technologies and drugs that promise a longer and healthier life. Add a public eager to obtain the latest breakthroughs touted in the media and over the Internet, plus a well-stocked medical industry eager to meet that demand, and it is easy to understand why expenditures continue to soar. On the other hand, payers for medical care—health insurance companies, government (federal, state, and local), and employers—increasingly bridle at medical care costs.

The United States continues to lead the world in health care expenditures.[4] In 2011, it spent more than $2.7 trillion, amounting to 17.9% of the gross domestic product. Most policy analysts contend that this rate of increase in medical care expenditures is unsustainable, but this claim has been made for many years. A potent combination of supply and demand factors explains why the United States spends so much.[5] On the supply side, the United States far exceeds other countries in the availability and use of expensive diagnostic technologies, such as magnetic resonance imaging and computed tomography. For example, the United States has four times as many magnetic resonance imaging machines per capita as does Canada. Similar patterns exist for therapeutic technologies, whether coronary angioplasty, cancer chemotherapy, or joint prostheses. The differences are especially dramatic in older patients. Other supply factors that drive high medical expenditures in the United States include a fee-for-service payment system that compensates physicians much more when they use expensive technologies than when they do not[6]; a medical professional work force that earns much higher incomes relative to the population than in other nations and that emphasizes specialist rather than generalist practice; accelerated development of new and costly medications that are directly marketed to consumers; much higher administrative costs; higher rates of fraud and abuse; and a high rate of defensive medicine in response to pervasive fears about medical malpractice suits. Supply factors that do not appear to be unique to the United States are the number of physicians or hospitals. Many other developed countries have a much larger physician work force relative to their population, as well as a much higher ratio of primary care physicians to specialists. The number of hospitals and hospital beds, the frequency of hospitalizations, and the length of hospital stay are relatively low in the United States, although it does have a much greater proportion of intensive care beds. Finally, recent analyses suggest that a principal driver of high expenditures on health care in the United States is the much greater price charged per unit of service compared with other developed countries.

Demand factors also drive medical expenditures. The extent to which the media and the medical profession feature medical "breakthroughs" is extensive and one-sided. New promising treatments merit front-page stories and commercial advertisements, whereas subsequent disappointing results are buried or ignored. The cumulative result is to whet patients' appetite for more and to leave the impression that good health depends only on finding the right treatment. This same quest explains the popularity of alternative medicine, for which patients are willing to spend $34 billion annually out of their own pockets (Chapter 39). The cumulative impact of these supply and demand drivers is that there are incentives to do more at every step of the American medical system.[5]

It could be argued that rising expenditures for medical care are not a bad thing. What could be more important than ensuring maximal health? There are several rebuttals to that argument. First, it is not clear that money spent on medical care brings appropriate value in the United States, given that its health statistics are worse than those of virtually every other developed country. Second, there are substantial regional differences in the supply and use of medical care, such as a two-fold difference in the supply of acute hospital beds and a four-fold difference in the risk of being hospitalized in an intensive care unit at the end of life. Similar regional differences exist for procedures such as transurethral prostatectomy, hysterectomy, and coronary artery bypass surgery. Yet there is no evidence that "more is better" on a regional basis.

Consequently, rising health care expenditures are stressing public programs such as Medicare, Medicaid, the Veterans Administration health system, and municipal hospitals, with budget requests outstripping the tax base to pay for them. Medical debt is by far the most important cause of bankruptcy. Finally, as health care becomes less affordable for businesses and

government, the number of people without health insurance will continue to increase.

Cost-Containment Strategies

Since the mid-1970s, a variety of strategies to contain rising medical expenditures have yielded limited success.[5] These attempts have tried to restrict the supply of costly medical technologies as well as the production of physicians, especially specialists; to promote health maintenance organizations that have incentives to spend less on medical care; to ration indirectly by limiting health insurance coverage; to institute prospective payment for hospital care; to use capitation payments or discounted fee schedules for physician reimbursement; to introduce gatekeeper mechanisms to reduce access to costly care; to put patients at more financial risk for their own medical care; to reform malpractice procedures; to reduce administrative costs; and to encourage less aggressive care at the end of life. The most recent suggestions—comparative effectiveness research to curtail the use of unnecessary technology, electronic medical records to avoid duplication of tests, payment for performance, accountable care organizations that change payment incentives—all hold promise to improve quality, but their potential for substantial cost reduction is only theoretical at present.

Recently, however, the rate of increase in health care expenditures has slowed relative to the gross domestic product.[7] Two basic hypotheses have been offered: the recession that began in 2008, and heightened cost consciousness among hospitals, health insurers, and some physician groups.

Payment for medical care varies by country. In the United States, health insurance coverage is an incomplete patchwork, consisting of government-sponsored programs for elderly people (Medicare), poor people (Medicaid), and veterans, plus employer-based coverage for workers and their families. Medicare covers acute care services in the hospital and in physicians' offices but has limited coverage for prescription drugs and long-term care. More than half of all Medicare subscribers also buy supplemental insurance. Medicaid covers more services than Medicare does, but Medicaid payments to physicians and hospitals are so low in many states that patients have restricted access to care. At any given time, more than 44 million Americans have lacked health insurance, and 70 million have been without insurance at some point during the year. In addition, millions of immigrant workers are also uninsured. The lack of health insurance contributes to poor health, such as delayed diagnosis and undertreatment of asthma, diabetes, hypertension, and cancer.

The 2010 Patient Protection and Affordable Care Act (ACA) contains numerous insurance reform features that took effect in 2010 and 2011, as well as coverage expansions that began in 2014.[8] The ACA was originally expected to cover 32 million previously uninsured Americans, with about half enrolling in subsidized private insurance plans and half in expanded state Medicaid programs. However, a 2012 Supreme Court decision gave states the choice of opting out of the Medicaid expansion. As a result, only 27 states plus the District of Columbia accepted that expansion. States that opted out of Medicaid expansion, such as Texas, tend to be those with the highest proportion of uninsured—mainly poor—people. In addition, various coverage components, especially regarding contraception, continue to be litigated. Revenue-generating provisions of the ACA are split about evenly between spending reductions and cost containment. In contrast to what happened after the passage of Medicare and Medicaid, the ACA continues to be highly controversial politically, and thus subject to potential changes, depending on election results.

Because medical care is both so valued and so expensive, physicians everywhere will inevitably become more involved in issues of medical economics. As cost-containment pressures force patients to assume more of their medical expenses, patients will become more aware of costs and more demanding about the price and value of care. In addition, knowledge will continue to accumulate about the real and potential harm from unnecessary or marginally useful medical services. Thus, informed clinical decision making will require that physicians have accurate information about the risks, benefits, and costs of medical care and better ways to communicate what is known and what is not.

REVIEW QUESTIONS

1. Preventing premature mortality is a prime goal for all clinicians. Of the following statements regarding premature mortality, which one is incorrect?

A. About 10% of premature deaths could be prevented by assuring high-quality medical care to all.
B. Among the various general causes of premature deaths, behavioral factors such as risky sexual behavior, alcohol and drug abuse, smoking, and obesity and physical inactivity are the most important and also offer opportunities for remediation.
C. Among behavioral factors, the most important cause of premature death is smoking cigarettes.
D. As smoking prevalence gradually decreases, the remaining smokers are smoking more cigarettes per day.
E. Based on current trends, obesity and physical inactivity will likely become more important causes of premature deaths.

Answer: D Statement A is correct. As important as good medical care is, the lack of such services only accounts for about 10% of premature deaths. Statements B, C, and E are correct. As regards statement D, at the same time as overall smoking prevalence has declined, the number of daily cigarettes consumed by those who continue to smoke has also declined. This decline is probably of function of several factors, including rising tobacco taxation that makes smoking more expensive, the spread of clean indoor air laws, and the increasing stigma attached to smoking.

2. Increasing evidence points to the important health impacts of social economic status (SES). Which one of the following statements regarding health and social class is correct?

A. Among the various components of SES, racial and ethnic characteristics contribute the most to health disparities.
B. Virtually all of the worst health among low SES populations can be explained by personal behaviors such as cigarette smoking and drug and alcohol abuse.
C. The relationship between SES and health is concentrated among those with low SES. In other words, for people above 400% of the poverty level, SES does not contribute to health status.
D. Because so many of the determinants of low SES (e.g., education, income, housing, net wealth) are outside the purview of clinicians, they should not be concerned about them.
E. Co-location of access to important social services—such as food stamps or disability payments—at medical sites can improve the social status of selected patients.

Answer: E Answer A is incorrect. Class, as measured by income, net wealth, educational status, and neighborhood, is the most important factor leading to health disparities. Regarding answer B, although personal behaviors such as smoking and physical activity are important, many other factors associated with low social class contribute to poor health. Regarding answer C, there is a stepwise association between SES and health, even at the higher levels of SES. For example, those in the top decile of SES enjoy better health than those in the ninth decile, even though both deciles have high SES. For answer D, it is true that clinicians would have a hard time improving these factors. Nevertheless, they should be conscious of them because they often influence treatment strategies (e.g., the ability to obtain nutritious food or to buy medications). Finally, answer E is correct. For example, convenient provision of food stamps for those with food insecurity would help stabilize diabetic patients.

3. Regarding per capita medical expenditures, population health, and access to medical care, which statement best expresses the performance of the United States versus other developed nations?

A. It leads the world in medical expenditures but trails badly in health outcomes and access to health care services.
B. It trails the world in medical expenditures, health outcomes, and access to care.
C. It is about in the middle for expenditures, health, and access.
D. It leads the world in expenditures, health, and access.
E. It leads the world in expenditures and health but lags in access.

Answer: A Answer A is correct as written. Of the three statements in answer B, only the second is correct. Of the three answers in C, none are correct. Of those in D, only the first is correct. And of those in E, only the first is correct.

4. Regarding the causes of rising medical expenditures in the United States, which answer is correct?

A. Fee-for-service payment to physicians is no longer a major driver of cost escalation because it will soon be replaced by bundled or capitated payment.
B. The United States is an outlier in that it has more hospital beds per capita and a higher length of stay.
C. The United States is an outlier in that it features more physicians per capita.
D. There are multiple factors responsible for the patterns of expenditures in the United States, and it is unlikely that any one bears major responsibility for the high expenditure profile.
E. The threat and reality of malpractice suits, in a country with the highest number of lawyers per capita, is the major reason for high U.S. medical expenditures.

Answer: D For answer A, although there is much current talk about the imminent demise of fee-for-service payment, it remains the dominant way of paying physicians. Regarding answer B, the United States actually has fewer hospital beds per capita than other developed countries as well as a shorter length of stay. The cost of a day in the hospital, however, is far higher in the United States. Similarly, for answer C, the United States has fewer physicians per capita than most developed nations but has a much higher proportion of specialists. Answer D, the correct answer, reflects the multiple reasons that medical care is more costly in the United States. Regarding answer E, malpractice suits are indeed more of a factor in the United States than other nations. Nevertheless, if all malpractice costs were to vanish, the United States would still have the most expensive health care system by far.

5. Regarding responses to high medical expenditures in the United States, which of the following statements is most correct?

A. Because expenditures on medical care are so essential and because wealthy countries characteristically spend more on health care as wealth increases, there is little interest in curtailing rising medical expenditures.
B. The cost-containment measures found in the Patient Protection and Affordable Care Act will be sufficient to rein in rising medical costs.
C. The combination of pressures on personal and governmental health care spending and crowding out of other social expenditures makes it likely that more intense cost-containment activity will occur.
D. The combination of widespread electronic medical record use and the spread of Accountable Care Organizations will be sufficient to curb rising medical expenditures.
E. Political obstacles to cost containment, such as the fear of rationing, will not be a problem.

Answer: C Answer A is incorrect. There is emerging consensus that something must be done to curtail rising medical expenditures (as phrased in answer C), but not on how to accomplish that. Although there are some cost-containment features in the Patient Protection and Affordable Care Act (PPACA) (answer B), it is unproved whether they will reduce medical expenditures. Answer C is correct. Regarding answer D, there is no good evidence that either the spread of electronic medical records or Accountable Care Organizations will curb rising medical expenditures, despite the enthusiasm of advocates for those programs. Finally, political obstacles (answer E) remain potent barriers to medical cost containment, such as the assertion during the debate over the PPACA that access to palliative care services would be tantamount to creating death panels.

GLOBAL HEALTH

ARUN CHOCKALINGAM

Health is a human right, but more than 2 billion people live with a daily income of less than $2 and have no access to good health care. Health is determined by the context of people's lives. Individuals are unable to control many of the social determinants of health (Chapter 5), such as income and social status, education, physical environment, social support network, genetics, health services, and gender.[1]

In the process of modernization from a less developed to a more developed nation, the epidemiologic transition of modern sanitation, medications, and health care has drastically reduced infant and maternal mortality rates and extended average life expectancy. As a result, the world has progressed from the age of pestilence and famine, with a life expectancy between 20 and 40 years, to the age of receding pandemics, with a life expectancy of 30 to 50 years, and now to the current age of degenerative and man-made diseases, with a life expectancy of 60 years or more.

These trends, coupled with subsequent declines in fertility rates, have driven a demographic transition in which the major causes of death change from infectious diseases to chronic and degenerative diseases.[2] As many countries around the world have undergone globalization, owing to their internal urbanization, modernization, and economic development, an increased proportion of their burden of morbidity and mortality is now due to chronic noncommunicable diseases, including cardiovascular, cerebrovascular, and renovascular diseases as well as cancer, diabetes, chronic respiratory diseases, and mental disorders (Table 6-1).

WHAT IS GLOBAL HEALTH?

The term *global health* is sometimes confused with public health, international health, tropical medicine, and population health. Global health, which is defined as the health of populations in a global context, transcends the perspectives and concerns of individual nations and crosses national borders. Global health depends on the public health efforts and institutions of all countries, including their strategies for improving health, both population-wide and for individuals. Global health depends on multiple factors, including social, political, environmental, and economic determinants of health. Although global health often focuses on improving the health of people who live in low- and middle-income countries, it also includes the health of any marginalized population in any country.

Global health requires use of a wide range of institutions that collaborate in addressing all health issues. Global health also depends on the constructive use of evidence-based information to provide health and health equity, in part by strengthening primary health care and the health care delivery system.

Millennium Development Goals

In an attempt to address global inequity, the United Nations advanced eight millennium development goals with the objective of achieving these goals between 2000 and 2015. These eight goals incorporate 21 targets (Table 6-2), with a series of measurable health and economic indicators for each target.[3] Although many of the targets have not yet been achieved, substantial progress has been made toward all targets.

The millennium development goals emphasize that health and development are interconnected. To address global inequity, fundamental issues include reducing poverty, improving education, and empowering people. In addition to specific goals for reducing infant and child mortality, maternal mortality, and mortality due to infectious diseases such as human immunodeficiency virus infection/acquired immunodeficiency syndrome (HIV/AIDS), malaria, and tuberculosis, the millennium development goals strongly encourage environmental sustainability and global partnership.

GLOBAL BURDEN OF DISEASES

The global burden of disease is measured in terms of total and cause-specific mortality and morbidity as well as the national economic burden for health care. The Global Burden of Diseases, Injuries and Risk Factors Study 2010[4] shows that an estimated 53 million people died from all causes in 2010, with

TABLE 6-1 EPIDEMIOLOGIC TRANSITION IN CARDIOVASCULAR DISEASES

STAGES OF DEVELOPMENT	LIFE EXPECTANCY	BURDEN OF CARDIOVASCULAR DISEASE DEATHS, % OF TOTAL DEATHS	PREDOMINANT CARDIOVASCULAR DISEASES AND RISK FACTORS	MODERN REGIONAL EXAMPLES
1. Age of pestilence and famine	20-40 years	5-10	Infections, rheumatic heart disease, and nutritional cardiomyopathies	Rural India, sub-Saharan Africa, South America
2. Age of receding pandemics	30-50 years	10-35	As above plus hypertensive heart disease and hemorrhagic strokes	China
3. Age of degenerative and man-made diseases	50->60 years	35-65	All forms of strokes; ischemic heart disease at young ages; increasing obesity and diabetes	Aboriginal communities, urban India, former socialist economies
3A. Age of delayed degenerative diseases	>60 years	<50	Stroke and ischemic heart disease at old age	Western Europe, North America, Australia, New Zealand
3B. Age of health regression and social upheaval	50-60 years	35-55	Re-emergence of deaths from rheumatic heart disease, infections, increased alcoholism and violence; increase in ischemic and hypertensive diseases in the young	Russia

During stages 1 to 3A, life expectancy increases, whereas life expectancy decreases in stage 3B compared with stage 3A and even stage 3.

Reprinted from *The Milbank Memorial Fund Quarterly*. 1971;49:509-538; and Yusuf S, Reddy S, Ounpuu S, et al. Global burden of cardiovascular diseases: part I: general considerations, the epidemiologic transition, risk factors, and impact of urbanization. *Circulation*. 2001;104:2746-2753.

TABLE 6-2 MILLENNIUM DEVELOPMENT GOALS AND TARGETS (2000-2015)

GOAL 1: ERADICATE EXTREME POVERTY AND HUNGER
Target 1A: Halve, between 1990 and 2015, the proportion of people living on less than $1.25 a day. Target 1B: Achieve decent employment for women, men, and young people. Target 1C: Halve, between 1990 and 2015, the proportion of people who suffer from hunger.
GOAL 2: ACHIEVE UNIVERSAL PRIMARY EDUCATION
Target 2A: By 2015, all children (girls and boys) can complete a full course of primary schooling.
GOAL 3: PROMOTE GENDER EQUALITY AND EMPOWER WOMEN
Target 3A: Eliminate gender disparity in primary and secondary education preferably by 2005, and at all levels by 2015.
GOAL 4: REDUCE CHILD MORTALITY RATES
Target 4A: Reduce by two thirds, between 1990 and 2015, the under-five mortality rate.
GOAL 5: IMPROVE MATERNAL HEALTH
Target 5A: Reduce by three quarters, between 1990 and 2015, the maternal mortality ratio. Target 5B: Achieve, by 2015, universal access to reproductive health.
GOAL 6: COMBAT HIV/AIDS, MALARIA, AND OTHER DISEASES
Target 6A: Have halted by 2015 and begun to reverse the spread of HIV/AIDS. Target 6B: Achieve, by 2010, universal access to treatment for HIV/AIDS for all those who need it. Target 6C: Have halted by 2015 and begun to reverse the incidence of malaria and other major diseases.
GOAL 7: ENSURE ENVIRONMENTAL SUSTAINABILITY
Target 7A: Integrate the principles of sustainable development into country policies and programs; reverse loss of environmental resources. Target 7B: Reduce biodiversity loss, achieving, by 2010, a significant reduction in the rate of loss. Target 7C: Halve, by 2015, the proportion of the population without sustainable access to safe drinking water and basic sanitation. Target 7D: By 2020, to have achieved a significant improvement in the lives of at least 100 million slum-dwellers.
GOAL 8: DEVELOP A GLOBAL PARTNERSHIP FOR DEVELOPMENT
Target 8A: Develop further an open, rule-based, predictable, non-discriminatory trading and financial system. Target 8B: Address the special needs of the least developed countries. Target 8C: Address the special needs of landlocked developing countries and Small Island developing States. Target 8D: Deal comprehensively with the debt problems of developing countries through national and international measures in order to make debt sustainable in the long term. Target 8E: In cooperation with pharmaceutical companies, provide access to affordable, essential drugs in developing countries. Target 8F: In cooperation with the private sector, make available the benefits of new technologies, especially information and communications.

From United Nations Millennium Development Goals. http://www.un.org/millenniumgoals/poverty.shtml. 2008. Accessed January 21, 2015.

13.2 million (25%) deaths due to communicable, maternal, neonatal, and nutritional disorders; 34.5 million (65%) due to noncommunicable diseases; and 5.1 million (10%) due to injuries (Table 6-3).[5] Although overall deaths between 1990 and 2010 increased by 13.5%, medical and public health advancements reduced deaths from communicable diseases by 17%, whereas deaths due to noncommunicable disease increased by 30% and deaths due to injury, including war-related deaths, increased by 24%.

CHANGING PATTERNS OF DISEASES

Despite the general trends of declining morbidity and mortality from communicable diseases, parts of Africa, Asia, and Latin America are still facing the challenges of infectious diseases, such as HIV infection, malaria, and tuberculosis, even as their prevalence of chronic noncommunicable diseases has risen—a so-called double burden. Concerted global health efforts and public awareness as well as investments by industrialized countries, multilateral agencies, and nongovernmental organizations have resulted in significant progress against HIV/AIDS (Chapter 384). Despite all of these efforts, however, the worldwide mortality due to HIV/AIDS and tuberculosis rose by 50% in 2010 compared with 1990 (Table 6-3). Although malaria deaths have fallen worldwide during the last decade, malaria is a rising threat in parts of Southeast Asia—especially Cambodia, Myanmar, Thailand, and Vietnam—where drug resistance to antimalaria medications is a problem.

TABLE 6-3 GLOBAL DEATHS IN 1990 AND 2010 FOR ALL AGES AND BOTH SEXES COMBINED

CAUSES OF DEATH	ALL AGES—DEATHS (THOUSANDS) 1990	2010	% CHANGE
All causes	46,511	52,769	+13
Communicable, maternal, neonatal, and nutritional disorders	15,859	13,156	−17
HIV/AIDS and tuberculosis	1770	2661	+50
Diarrhea, lower respiratory infection, and other common IDs	7772	5277	−32
Neglected tropical diseases and malaria	1211	1322	+ 9
Maternal disorders	359	255	−29
Neonatal disorders	3081	2236	−42
Nutritional deficiencies	977	684	−30
Other communicable, maternal, neonatal, and nutritional disorders	690	721	+5
Noncommunicable diseases	26,560	34,540	+30
Neoplasm	5779	7978	+38
Cardiovascular and circulatory diseases	11,903	15,616	+31
Chronic respiratory diseases	3986	3776	−5
Cirrhosis of the liver	778	1031	+33
Digestive diseases (except cirrhosis)	973	1112	+14
Neurologic disorders	595	1274	+14
Mental and behavioral disorders	138	231	+68
Diabetes, urogenital, blood, and endocrine diseases	1544	2726	+77
Musculoskeletal disorders	70	154	+121
Other noncommunicable diseases	794	642	−19
Injuries	4092	5073	+24
Transport injuries	958	1397	+46
Unintentional injuries other than transport injuries	2030	2123	+5
Self-harm and interpersonal violence	1009	1340	+33
Forces of nature, war, and legal intervention	95	214	+125

HIV/AIDS = human immunodeficiency virus infection/acquired immunodeficiency syndrome; ID = infectious diseases.
From Lozano R, Naghavi M, Foreman K, et al. Global and regional mortality from 235 causes of death for 20 age groups in 1990 and 2010: a systematic analysis for the Global Burden of Disease Study 2010. *Lancet*. 2012;380:2095-2128.

Noncommunicable diseases account for nearly two thirds of the global burden of disease. Nearly 80% of all noncommunicable diseases related to death and disability occur in the low- and middle-income countries, where they account for about 14 million deaths in people younger than 60 years. The prevention and control of noncommunicable diseases should involve both upstream and downstream approaches, such as social determinants; national and international policies regarding trade, agriculture, transportation, and environmental and other policies; health care, including accessibility, availability, and affordability; and settings, such as schools and worksites, where health promotion and disease prevention are targeted, as well as media by which health can be influenced.

Among noncommunicable diseases, cardiovascular diseases account for the largest burden of disease. One of the major worldwide risk factors for cardiovascular disease is hypertension (Chapter 67), which has an estimated prevalence of 35% to 45% of the global population—more than 2 billion people older than 25 years. The prevalence of hypertension is highest in Africa, where it is about 45% for both sexes, and lowest in the Americas, where it is about 35% for both sexes (Fig. 6-1). In all regions, men have a slightly higher prevalence of hypertension than do women. Despite significant efforts by global nongovernmental organizations and the World Health Organization, more than 50% of the world's population with hypertension does not even know their condition, and the percentage treated and controlled varies from less than 5% in Zambia to 66% in Canada.

As noncommunicable diseases have reached an epidemic proportion, all 192 United Nations Member States agreed to address their prevention and control worldwide, particularly in developing countries. The emphasis is on four major noncommunicable diseases (cardiovascular diseases, cancer, diabetes, and chronic respiratory diseases) and four key risk factors common to all four of these noncommunicable diseases (tobacco use, unhealthy diets, physical inactivity, and harmful use of alcohol). The World Health Organization developed a global monitoring framework to enable global tracking of progress in preventing and controlling these four major noncommunicable diseases and their key risk factors, aiming for a 25% reduction by 2025—with a slogan of *25 By 25*.[6]

Noncommunicable diseases represent a growing economic threat across the globe and are becoming an acute problem in low- and middle-income countries in which they are estimated to account for nearly $500 billion per year.[7] By contrast, worldwide adoption of best practices could substantially reduce that economic burden. For example, population-based interventions to reduce tobacco and harmful alcohol use as well as to improve unhealthy diets and to increase physical activity are estimated to cost less than $0.40 per person per year. These low-technology, population-wide interventions along with individual-based noncommunicable disease "best buy" interventions, such as individualized counseling and drug therapy, bring the total annual cost to $11.4 billion. Thus, on a per capita basis, the annual investment ranges from less than $1 in low-income countries to $3 in upper middle-income countries.

The growing epidemic of noncommunicable diseases, including mental health conditions, and the unfinished agenda of controlling infectious diseases (HIV/AIDS, malaria, tuberculosis, maternal and child health, and other infectious and parasitic diseases) pose a huge threat to the global population in terms of both human and fiscal losses. Although individual countries theoretically take responsibility for the health of their respective citizens, many low- and middle-income countries are unable to meet their domestic population's basic needs. The sum of public and private health care expenditure by countries based on their gross domestic product varies from 1.6% in South Sudan to 18% in the United States, with many high-income countries spending more than 10%. Thus, the worldwide solution requires a response of all of human society, including strategic domestic and international investments, both within countries and through multilateral agencies. This societal responsibility must be shared by the private sector, nongovernmental organizations, academia, professional societies, and the public themselves.

The modern global health agenda should move beyond false dichotomies—such as prevention versus treatment, infectious versus noncommunicable diseases, primary care versus specialized care, social determinants versus health services, life sciences versus social sciences—toward integration in the sense of common purpose. The approach to noncommunicable diseases should be integrated with the approach to communicable diseases. Health

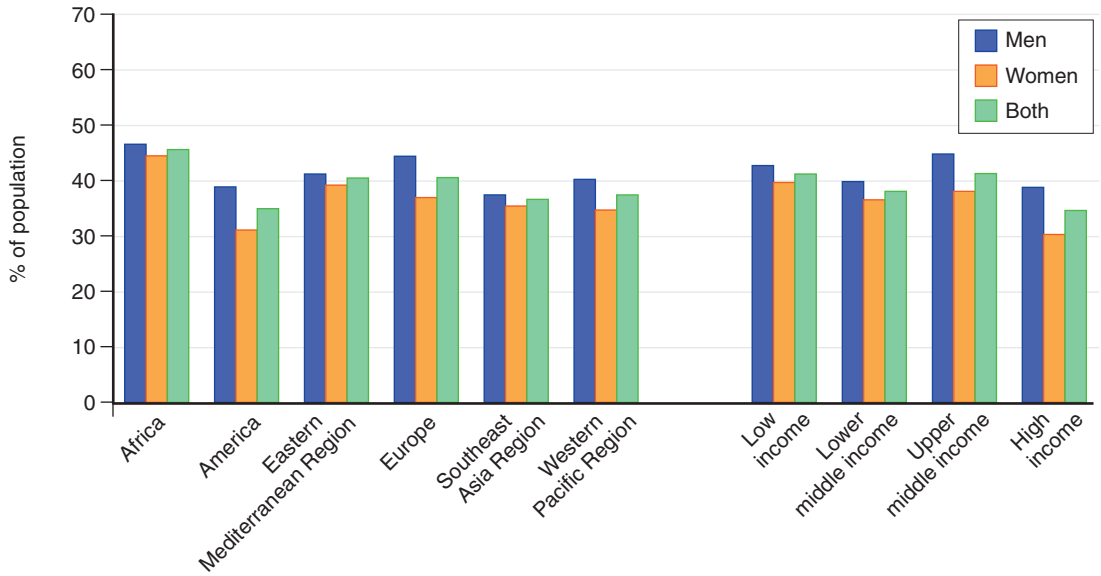

FIGURE 6-1. Global prevalence of hypertension. Age-standardized prevalence of hypertension, defined as systolic blood pressure ≥140 mm Hg or diastolic blood pressure ≥90 mm Hg or taking medications for lowering of blood pressure, in persons aged 25 years and older. (Data source: Noncommunicable Disease Global Monitoring Framework. World Health Organization. 2013. http://www.who.int/nmh/global_monitoring_framework/en/. Accessed January 21, 2015.)

targets should include noncommunicable diseases such as hypertension, diabetes, and cervical cancer, even in low- and middle-income countries. A critical component of health is a healthy lifestyle throughout life, from childhood to adolescence to adulthood, including risk factor reduction as well as treatment when it becomes necessary. Global health must integrate prevention and treatment in a cost-effective manner.

REVIEW QUESTIONS

1. Based on the Global Burden of Disease Study 2010, which one of the following statements is correct?

A. The global burden of diabetes mellitus remained stable between 1990 and 2010.
B. Cancer is the leading cause of noncommunicable disease-related deaths.
C. Cardiovascular and circulatory deaths accounted for almost 30% of all deaths in 2010.
D. The total number of deaths due to HIV/AIDS and tuberculosis decreased in 2010 compared with 1990.
E. Forces of nature, war, and legal intervention decreased in 2010 compared with 1990.

Answer: C See Table 6-3. In 2010, the number of cardiovascular-related deaths was 15.6 million out of the total deaths of 52.8 million, amounting to 29.6%. The number of diabetes-related deaths in 1990 and 2010 were 1.5 million and 2.7 million, respectively. During those 20 years, diabetes mellitus increased by 76%. Cancer was the second leading cause of deaths in 2010. There were 8.0 million deaths due to cancer in 2010 compared with 15.6 million deaths from cardiovascular and circulatory causes. The number of deaths due to HIV/AIDS and tuberculosis in 2010 (2.7 million) increased by 50% compared with the 1990 number (1.8 million). Compared with 1990, deaths resulting from forces of nature, war, and legal intervention more than doubled (125%) by 2010.

2. Hypertension or high blood pressure is the major risk factor for heart disease, stroke, and kidney diseases worldwide. Which one of the following statements is incorrect?

A. The prevalence of hypertension, globally, after the age of 25 years varies between 35 and 45%.
B. Across all countries, men have a slightly higher prevalence of hypertension than do women.
C. The global hypertension control rate is about 60%.
D. Early diagnosis of hypertension leads to prevention of all forms of vascular complications.
E. According to the World Health Organization, population-attributable deaths due to hypertension are estimated at about 7.5 million per year.

Answer: C The global control rate varies from less than 5% in Zambia to 66% in Canada and is very low overall worldwide. All other statements (answers A, B, D, and E) are correct.

3. Which of the following statement about global health is correct?

A. Global health is not the opposite of domestic health.
B. Global health must integrate both infectious diseases and noncommunicable diseases.
C. Public, private, and societal partnership is necessary to deliver effective global health.
D. Academia has a major role in promoting global health.
E. All of the above.

Answer: E Statement A is true because global health includes domestic health as well, particularly the health of marginalized people in developed countries. Statement B is true because the current health system must address all diseases, particularly when noncommunicable diseases account for 65% of all global causes of death. New evidence shows that one fifth of all cancers worldwide are caused by chronic infections produced by agents such as HIV, human papillomavirus, and hepatitis B virus. Infections and parasitic diseases also cause other noncommunicable diseases, such as rheumatic heart disease, Chagas disease, cardiomyopathy, and peptic ulcer. As HIV/AIDS survivors live longer, they also are exposed to lifestyle-related risk factors and noncommunicable diseases. Statement C is true. The economic burden of diseases is so large that public-private partnership is essential. Statement D is true. Academia should develop and supply needed knowledge and train the next generation of the global health work force.

7

APPROACH TO THE PATIENT: HISTORY AND PHYSICAL EXAMINATION

DAVID L. SIMEL

OVERVIEW

Physicians may have multiple objectives with varying degrees of importance in their encounters with patients. These goals include, but are not limited to, the translation of symptoms and signs into diagnoses, the assessment of stability or change in known conditions, the provision of information and counseling for future prevention, and the reaffirmation or alteration of therapeutic interventions. A general health check will increase the number of diagnoses for a patient, but it may not affect overall morbidity and mortality.[1]

The interaction between the patient and physician represents not only a scientific encounter but also a social ritual centered on locus of control and meeting each other's expectations. Patients expect that their health care needs and concerns will be addressed competently. Physicians also have expectations: a need to feel that they have not missed something important in addressing diagnostic challenges, a need to put limits on the time available for each interaction, and a need to maintain objectivity so that their evaluation and recommendations are not clouded by their emotional feelings about the patient. The expertly performed rational clinical examination enhances the expected social ritual and the likelihood of acquiring relevant data. It also optimizes the physician's ability to understand the patient's symptoms and concerns, as well as to facilitate the healing process.[2]

Physical Examination Begins with the History

It is almost impossible to consider the history as distinct from the physical examination because the clinical examination begins as soon as the physician sees or hears the patient. From the patient's perspective, it matters little whether the physician determines the diagnosis from the history or the physical examination. The concept of deliberate practice, which has been demonstrated to be important in performing arts and in sports, can be applied to the performance of the clinical examination. This deliberate practice, which must be specifically designed to improve the ability to elicit symptoms and signs, requires appropriate training under observation, concentration, and commitment to ensure its consistent and accurate performance. The creation of simulation centers at many medical schools and hospitals provides new opportunities for this training.

Quantitative Principles of the Clinical Examination

The diagnostic accuracy of a symptom or sign is quantified by its sensitivity and specificity, often described as its likelihood ratio (LR) or predictive value (Chapter 10). Data on diagnostic accuracy can be obtained by a literature search for the evaluation of a disease-specific condition (e.g., melanoma) or a clinical finding (e.g., splenomegaly) (E-Tables 7-1 and 7-2). Each component of the history and physical examination has an associated sensitivity (the percentage of patients with a disorder who have an abnormal finding) and specificity (the percentage of patients without a disorder who have a normal finding). Measures of precision, such as the kappa (κ) statistic (0 = random agreement; +1 = perfect agreement), quantify the agreement between observers on a symptom or sign (Chapter 10). Current research on the clinical examination uses LRs that inform clinicians how likely they are to observe a particular finding in a patient with a given condition as opposed to a patient without the condition. A patient with an abnormal glabellar tap has an LR of 4.5 for Parkinson disease (Chapter 409), which means that the risk for Parkinsonism increases 4.5-fold compared with that in a patient who does not have the finding. Similarly, a patient who insists that he or she does not have "shaking in the arms" has an LR of 0.25 for Parkinson disease and is one fourth as likely (a reduced chance) to have the disease compared with the baseline risk.

MEDICAL HISTORY

The history begins by asking patients to describe, in their own words, the reason for seeking medical care (Table 7-1). Although patients may have many reasons for initiating a visit to the physician, they should be encouraged to select the one or two most important concerns they have. The physician should reassure the patient that other concerns will not be ignored, but that it is important to understand what is most concerning to the patient.

History of the Present Illness

Open-ended questions facilitate descriptions of problems in the patient's own words. Subsequently, specific questions fill in gaps and help clarify important points. These questions should be asked in an order dictated by the story the patient tells and targeted to suit the individual problem. When the patient is acutely ill, the physician should limit the amount of time spent in open-ended discussion and move promptly to the most important features that allow quick evaluation and management. In general, the history of the problem under consideration includes the following:

- Description of onset and chronology
- Location of symptoms
- Character (quality) of symptoms
- Intensity
- Precipitating, aggravating, and relieving factors
- Inquiry into whether the problem or similar problems occurred before and, if so, whether a diagnosis was established at that time

It is often helpful to ask patients to express what they believe is the cause of the problem or what concerns them the most. This approach often uncovers other pertinent factors and helps establish that the physician is trying to meet the patient's needs.

Past Medical and Surgical History

An astute clinician recognizes that patients may not report all their prior problems because they may forget, may assume that previous events are unrelated to their current problem, or simply may not want to discuss past events. Open-ended statements such as "Tell me about other medical illnesses that we did not discuss" and "Tell me about any operations you had" prompt the patient to consider other items. The physician should ask the patient about unexplained surgical or traumatic scars.

A list of current medications includes prescriptions, over-the-counter medications, vitamins, and herbal preparations. Patients who do not recall the names of medications should bring all medication bottles to the next visit. Patients may not consider topical medications (e.g., skin preparations or eyedrops) as important, so they may need prompting.

Information about allergies (Chapter 254) is particularly important, but challenging, to collect. Patients may attribute adverse reactions or intolerances to allergies, but many supposed allergic reactions are not truly drug allergies. For example, less than 20% of patients who claim a penicillin allergy are allergic on skin testing. Eliciting the patient's actual response to medications facilitates a determination of whether the response was a true allergic reaction.

Social and Occupational History and Risk Factors

The social history not only reveals important information but also improves understanding of the patient's unique values, support systems, and social situation. It can be helpful to ask the patient to describe what they would do during a typical day. Patients who lack confidence when filling out medical forms by themselves have an LR positive of 5.0 for problems with health care literacy.[3]

Data that may influence risk factors for disease should be gathered, including a nonjudgmental assessment of substance abuse. The tobacco history should include the use of snuff, chewing tobacco, and cigar and cigarette smoking (Chapter 32). Alcohol use should be determined quantitatively and by the effect that it has had on the patient's life (Chapter 33). Past or present use of illicit substances, prescription pain medications or sedatives, and intravenous drugs should be assessed (Chapter 34). The sexual history should address sexual orientation and gender identity, as well as current and past sexual activity. The physician can initiate this discussion with the question, "Do you have any concerns or questions about your sexuality, sexual orientation, or sexual desires?"[4] The employment history should include the current and past employment history, as well as any significant hobbies. All adult patients should be asked if they served in the military. Military veterans should be asked about their combat history, years of service, and areas of deployment (Table 7-2).[5]

The physician should also obtain information on socioeconomic status, insurance, the ability to afford or obtain medications, and past or current barriers to health care because of their impact on care of the patient (Chapter

E-TABLE 7-1 MEDLINE SEARCH STRATEGY FOR IDENTIFYING QUANTITATIVE INFORMATION ON THE CLINICAL EXAMINATION USING THE OVID SEARCH SYSTEM* TO SEARCH FOR STUDIES ON MELANOMA

3. professional competence.mp
4. (sensitivity and specificity).mp or (sensitivity and specificity).tw
5. (reproducibility of results or observer variation).mp
6. diagnostic tests, routine/
7. (decision support techniques or Bayes theorem).mp
8. 1 or 2 or 3 or 4 or 5 or 6 or 7
9. limit 8 to (Ovid full text available and human and English language)
10. exp melanoma
11. 9 and 10

*OVID Technologies, Inc. A condition and a physical finding are given as examples. Abbreviations or search term abbreviations are as follows: "exp" indicates that the topic is "exploded" to include all subheadings for the topic. The "$" is a wildcard designator, so "exam$" would include the words *examination, examining*, and *examiner.* "mp" searches for the word or phrase in the title, abstract, registry number word, or mesh subject heading. Step 9 limits the search to studies that involve humans only and for which the full manuscript is available online and is written in English. If the search yields too few topics, the limitation of full text available can be removed and the search repeated. If too many results are obtained, some of the items from step 8 can be eliminated.

E-TABLE 7-2 PUBMED SEARCH STRATEGY FOR IDENTIFYING QUANTITATIVE INFORMATION ON THE CLINICAL EXAMINATION TO SEARCH FOR STUDIES ON SPLENOMEGALY

(splenomegaly[mh] AND (Humans[Mesh] AND English[lang])) AND ((physical examination[mh] OR physical exam*[title/abstract]) OR (medical history taking[mh]) OR (professional competence[mh]) OR ((sensitivity[title/abstract] AND specificity[title/abstract]) OR (sensitivity and specificity[mh])) OR (reproducibility of results[mh]) OR (observer variation[mh]) OR (diagnostic tests, routine[mh]) OR (decision support techniques[mh]) OR (bayes theorem[mh]))

The PUBMED search strategy may be too sensitive, with many articles found. Strategies to eliminate case reports and to constrain the search to full text availability will reduce high-yield results to a more manageable list.

TABLE 7-1 PATIENT'S MEDICAL HISTORY

Description of the patient
Age, gender, ethnic background, occupation
Chief reason for seeking medical care
State the purpose of the evaluation (usually in the patient's words)
Other physicians involved in the patient's care
Include the clinician that the patient identifies as his or her primary provider or the physician who referred the patient. Record contact information for all physicians who should receive information about the visit
History of the reason for seeking medical care
In chronologic fashion, determine the evolution of the indication for the visit and then each major symptom. It is best to address the patient's reason for seeking care first rather than what the physician ultimately believes is most important
Be careful to avoid "premature closure," in which a diagnosis is assumed before all the information is collected
Past medical and surgical history
List other illnesses and previous surgeries not related to the current problem
List all prescribed and over-the-counter medications with dose
Remember to ask about vitamin and herbal supplements
Allergies and adverse reactions
List allergic reactions to medications and food. Record the specific reaction (e.g., hives). Distinguish allergies from adverse reactions or intolerance to medication (e.g., dyspepsia from nonsteroidal anti-inflammatory agents)
Social, occupational, and military history (see Table 7-2)
Describe the patient's current family and a typical day for patient. The occupational history should focus on current and past employment as it might relate to the current problem
Risk factors
Include history of tobacco use, illegal drug use, and risk factors for sexually transmitted disease (including human immunodeficiency virus and hepatitis)
Family history
History of any diseases in first-degree relatives and a listing of family members with any conditions that could be risk factors for the patient (e.g., cardiovascular disease at a young age, malignancy, known genetic disorders, longevity)
Review of systems (see Table 7-3)

TABLE 7-2 BASIC MILITARY HISTORY

- Tell me about your military experience.
- When and where do you/did you serve?
- What do you/did you do while in the service?
- How has military service affected you?

If the patient answers "yes" to any of the questions below, ask the patient, "Can you tell me more about that?"

- Did you see combat, enemy fire, or casualties?
- Were you or a buddy wounded, injured, or hospitalized?
- Did you ever become ill while you were in the service?
- Were you a prisoner of war?

To screen for post-traumatic stress disorder, ask, "In your life, have you ever had an experience so horrible, frightening, or upsetting that, in the past month you …

- Have had nightmares about it or thought about it when you did not want to?"
- Tried hard not to think about it or went out of your way to avoid situations that reminded you of it?"
- Were constantly on guard, watchful, or easily startled?"
- Felt numb or detached from others, activities, or your surroundings?"

From Department of Veterans Affairs. Military Health History Pocket Card for Clinicians. http://www.va.gov/oaa/pocketcard/military-health-history-card-for-print.pdf. Accessed February 9, 2015.

5). Marital status and the living situation (i.e., whom the patient lives with, significant stressors for that patient) are important as risk factors for disease and to determine how best to care for the patient. A patient's culture (Chapter 4) and values should be known, including any prior advance directives or desire to overrule them (Chapter 3). The physician should explicitly elicit and record information regarding the next of kin; surrogate decision makers; emergency contacts; social support systems; and financial, emotional, and physical support available to the patient.

Family History

The family history is never diagnostic, but it allows risk stratification, which affects the pretest probability for an increasing number of disorders (e.g., heart disease, breast cancer, or Alzheimer disease). For common diseases such as heart disease, additional inquiry into the age of onset in first-degree relatives and death attributed to the disease should be obtained (Chapter 52). When a patient reports that a first-degree relative had a myocardial infarction, the LR is 19 that the patient has a family history of myocardial infarction. Patients may lack appropriate information about the absence of disease, however, so a reported lack of a family history of myocardial infarction reduces the likelihood only by one third. In general, the specificity of the reported family history far exceeds its sensitivity; for example, only two thirds of patients with essential tremor (Chapter 410) report a family history, but 95% of such patients have first-degree relatives with tremor. The expansion of knowledge about genetic diseases (Chapter 40) requires clinicians not only to improve their skills in eliciting the family history but also to develop methods for confirming the information. For example, patients who report that a first-degree relative had carcinoma of the colon (LR 25), breast (LR 14), ovaries (LR 34), or prostate (LR 12) are usually providing accurate information.[6]

TABLE 7-3 REVIEW OF SYSTEMS*

FOCUS all questions on a specific time frame (e.g., within the past "month" or "now") and on items not already addressed during the clinical examination:
Change in weight or appetite
Change in vision
Change in hearing
New or changing skin lesions
Chest discomfort or sensation of skipped beats
Shortness of breath, dyspnea on exertion
Abdominal discomfort, constipation, melena, hematochezia, diarrhea
Difficulty with urination
Change in menses
Joint or muscle discomfort not already mentioned
Problems with sleep
Difficulty with sexual function
Exposure to "street" drugs or medications not already mentioned
Depression (feeling "down, depressed, or hopeless"; loss of interest or pleasure in doing things)
A sensation of unsteadiness when walking, standing, or getting up from a chair

*Clinicians may start with this basic list and adapt the items to their specific patient population by considering factors such as age, gender, medications, and the problems identified during the examination. The process is facilitated by developing a routine personal approach to these questions, typically going through the systems from "head to toe."

Review of Systems

The review of systems, which is the structural assessment of each of the major organ systems, elicits symptoms or signs that are not covered or may be overlooked in the history of the present illness (Table 7-3). Although a review of systems is required in many electronic records systems, it may only yield important diagnoses in less than 10% of patients, and the cost of pursuing false-positive findings is not known. In contrast to the open-ended nature of collecting the medical history, which allows the patient to "claim" or "deny" a variety of symptoms, the direct questioning technique of the review of systems leads the patient to "accept" or "reject" symptoms. The review of systems is more efficient if at least some questions are restricted to a specific time frame (e.g., "Has there been any recent change in your vision?" or "Have you recently had shortness of breath, wheezing, or coughing?") or by having the patient fill out a previsit questionnaire.

PHYSICAL EXAMINATION

Chaperones

Surveys suggest that most patients of either sex and all ages report a lack of preference for a chaperone, but it is not clear whether this response is their true feeling or a desire to give a "correct" response. Nevertheless, many adult women (29%) and adolescent girls (46%) do express a preference for a chaperone during a breast, pelvic, or rectal examination by a male physician (especially during their first examination). Examiners should offer patients the option of a chaperone, and a chaperone should be considered when the clinician and patient are of different genders. Many examiners prefer a chaperone to allay their own anxieties attributable to gender differences or to achieve a perceived need for protection should the patient become concerned during the procedure.

Vital Signs

Vital signs include the pulse rate and rhythm, blood pressure, respiratory rate, body temperature, and the patient's quantitative assessment of pain. Marked abnormalities require a rapid, focused evaluation that may take precedence

over the typical structural approach to the remainder of the evaluation (Chapter 8).

When the blood pressure is abnormal (Chapter 67), the measurement should be repeated, assuring that the cuff size is appropriate. Many adults require a large adult cuff; using a narrow cuff can alter systolic/diastolic blood pressure by −8 to +10/+2 to +8 mm Hg. The appearance of repetitive sounds (Korotkoff sounds, phase 1) constitutes systolic pressure. (Record the value rounded upward to the nearest 2 mm Hg.) After the cuff is inflated about 20 to 30 mm Hg above the palpated pressure, the Korotkoff sounds muffle and disappear as the pressure is released (phase 5). The level at which the sounds disappear is the diastolic pressure.

Respirations should be assessed with the patient unaware that the rate is being observed. The examiner should decide whether patients have tachypnea (a rapid rate of breathing) or hypopnea (a slow or shallow rate of breathing). Tachypnea is not always associated with hyperventilation, which is defined by increased alveolar ventilation resulting in a lower arterial carbon dioxide level (Chapter 103). The subjective sensation of dyspnea (Chapter 83) is caused by an increased work of breathing.[7]

The body temperature of adults is measured with an oral electric thermometer. Rectal thermometers reliably record temperatures 0.4° C higher than oral thermometers. Tympanic thermometers vary too much in comparison with oral thermometers (−1.2° to +1.6° C vs. the oral temperature) to be reliable in hospitalized patients.

As a vital sign measure, patients should self-rate any pain on a scale of 0 to 10 (no pain to worst pain ever) (Chapter 30). However, the validity, usefulness, and value of this approach as a screening tool for clinical diagnosis are uncertain.

Head and Neck

Face

The examiner should note any asymmetrical facial features. Examples of asymmetry include skin lesions (Chapter 436), cranial nerve palsies (Chapter 396), parotid enlargement (Chapter 425), or the ptosis of Horner syndrome (Chapter 424). A variety of disorders may cause symmetrical, abnormal facies; examples include acromegaly (Chapter 224), Cushing syndrome (Chapter 227), and Parkinson disease (Chapter 409).

Ears

Physicians may not recognize their patient's hearing impairment (Chapter 428). The inability to appreciate the whispered voice increases the likelihood of hearing loss (LR 6).[8] Otoscopic evaluation of the tympanic membranes should reveal a translucent membrane and an obvious cone of light reflected where the eardrum meets the malleolus (see Fig. 426-7). Cerumen impaction is an easily treated cause of diminished hearing.

Nose

Patients with nasal symptoms often incorrectly self-diagnose bacterial sinusitis (Chapter 426). The nares should be examined for the presence of polyps, which can be seen as obstructing, glistening mucosal masses. Transillumination performed in a dark room is useful for diagnosing sinusitis, especially when combined with visualization of a purulent discharge, a patient's report of a poor response to decongestants or antihistamines, a maxillary toothache, and the presence of discolored rhinorrhea (Chapter 426). These patients have an LR greater than 6 for rhinosinusitis.

Mouth

The quality of the patient's dentition directly affects nutrition. Premalignant oral lesions (e.g., leukoplakia [see Fig. 190-1], nodules, ulcerations) found by generalist physicians are usually verified by dentists (LR > 6.5) (Chapter 425). Patients who use smokeless tobacco products are at significantly increased risk for premalignant and malignant oral lesions (Chapter 32). Bimanual palpation of the cheeks and floor of the mouth facilitates identification of potentially malignant lesions (Chapter 425).

Eyes

The eye examination begins with simple visual inspection to look for symmetry in the lids, extraocular movements, pupil size and reaction, and the presence of redness (Chapters 423 and 424). Abnormalities in extraocular movements should be grouped into nonparalytic (usually chronic with onset in childhood) or paralytic causes (third, fourth, or sixth cranial nerve palsy). Pupillary abnormalities may be symmetrical or asymmetrical (anisocoria). Red eyes should be categorized by the pattern of ciliary injection, presence of pain, effect on vision, and papillary abnormalities. When the eye examination is approached systematically, the generalist physician can evaluate the likelihood of conjunctivitis, episcleritis or scleritis, iritis, and acute glaucoma.

Routine determination of visual acuity can confirm a patient's report of diminished vision but does not replace the need for formal ophthalmologic evaluation in patients with visual complaints (Chapter 423). Aging patients often experience acute flashes and floaters, especially with posterior vitreal detachments. If acute flashes and floaters are associated with visual loss, the patient should be urgently referred for an ophthalmologic examination for the evaluation of a possible acute retinal detachment.[9] Cataracts can be detected with direct ophthalmoscopy, but the generalist's proficiency in this evaluation is uncertain.

After identifying the optic disc by ophthalmoscopy, the examiner should note the border of the disc for clarity, color, and the size of the central cup in relation to the total diameter (usually less than half the diameter of the disc). A careful observer usually can see spontaneous venous pulsations that indicate normal intracranial pressure, but about 10% of patients with normal intracranial pressure will not have spontaneous pulsations. Abnormalities of the optic disc include optic atrophy (a white disc), papilledema (see Fig. 423-27) (blurry margins with a pink, hyperemic disc), and glaucoma (a large, pale cup with retinal vessels that dive underneath and that may be displaced toward the nasal side). The generalist's examination inadequately detects early glaucomatous changes, so high-risk patients should undergo routine ophthalmologic examination for glaucoma.[10]

After inspecting the disc, the upper and lower nasal quadrants should be examined for the appearance of vessels and the presence of any retinal hemorrhages (see Fig. 423-24) or lesions. Proceeding from the nasal quadrants to the temporal quadrants decreases the risk for papillary constriction from the bright light focused on the fovea. Dilating the pupils leads to an improved examination. Patients with diabetes (Chapter 229) should undergo routine examination by eye care experts because the sensitivity of a generalist's examination is not adequate to exclude diabetic retinopathy or monitor it over time.

Neck

Carotid Pulses

The carotid pulses should be palpated for contour and timing in relation to the cardiac impulse. Abnormalities in the carotid pulse contour reflect underlying cardiac abnormalities (e.g., aortic stenosis) but are generally appreciated only after detecting an abnormal cardiac impulse or murmur (Chapter 51).

Many physicians listen for bruits over the carotid arteries because asymptomatic carotid bruits are associated with an increased incidence of cerebrovascular and cardiac events in older patients (Chapters 406 and 407). In asymptomatic patients, the presence of a carotid bruit increases the likelihood of a 70 to 90% stenotic lesion (LR 4 to 10), but the absence of a bruit is of uncertain value. Unfortunately, clinical data do not provide adequate data for judging the importance of detecting bruits in asymptomatic patients.

Jugular Veins

The examination of the neck veins is an interesting but often unreliable indicator of central venous pressure or fluid responsiveness in hospitalized sick patients (Chapter 51).[11] Inspection of the waveforms may facilitate the interpretation of the cardiac examination for right heart valvular lesions. The waves are seen best by shining a penlight obliquely on the vein while the examiner looks for the dynamic changes of the projected shadow on the bed linen.

Thyroid

The thyroid gland is felt best when standing behind the patient and using both hands to palpate the thyroid gland gently (Chapter 226). Palpation is enhanced when the patient swallows sips of water to allow the thyroid to glide underneath the fingers. When viewed from the side, lateral prominence of the thyroid between the cricoid cartilage and the suprasternal notch indicates thyromegaly. The generalist physician should estimate the size of the thyroid gland as normal or enlarged; the impression of an enlarged thyroid gland by a generalist physician has an LR of almost 4, whereas assessment of normal size makes thyromegaly less likely (LR 0.4). The volume of a normal thyroid gland is no greater than the volume of the patient's distal thumb phalanx.

Lymphatic System

While palpating the thyroid, the examiner may also identify enlarged cervical lymph nodes (Chapter 168). Lymph nodes can also be palpated in the supraclavicular area, axilla, epitrochlear area, and inguinofemoral region. Simple

lymph node enlargement confined to one region is common and does not usually represent an important underlying disorder. Unexpected gross lymph node enlargement in a single area or diffuse lymph node enlargement is more important. Patients with febrile illnesses, underlying malignancy, or inflammatory diseases should routinely undergo an examination of each of the aforementioned areas for lymph node enlargement.

Chest

Inspection of the patient's posture may reveal lateral curves in the back (scoliosis) or kyphosis that may be associated with loss of vertebral height from osteoporosis (Chapter 243). When patients have back pain, the spine and paravertebral muscles should be palpated for spasm and tenderness (Chapter 400). The patient may be placed through maneuvers to assess loss of mobility associated with ankylosing spondylitis (Chapter 265), but a history of loss of lateral mobility may be just as efficient in the early stages of spondylitis.

Lungs

The incremental value of palpation and percussion of the chest to supplement the history, auscultation, and eventual chest radiograph is unknown. Normal vesicular sounds, which approximate a 3:1 inspiratory:expiratory ratio with no pause between phases, are heard throughout most of the normal posterior chest during quiet breathing. Auscultated wheezes are continuous adventitial sounds. Crackles (formerly called rales) are discontinuous sounds heard in conditions that stiffen the lung (heart failure, pulmonary fibrosis, and obstructive lung disease). The best piece of information for increasing the likelihood of chronic obstructive pulmonary disease is a history of more than 40 pack years of smoking (LR 19). The presence of wheezing or downward displacement of the larynx to within 4 cm of the sternum (distance between the top of the thyroid cartilage and the suprasternal notch) increases the likelihood of obstructive pulmonary disease (LR of 4 for either).

Heart

The patient should be examined in the sitting and lying positions (Chapter 51). Palpation of the apical impulse in the left lateral decubitus position helps detect a displaced apical impulse and can reveal a palpable S_3 gallop. When the apical impulse is lateral to the midclavicular line, radiographic cardiomegaly (LR 3.5) and an ejection fraction of less than 50% (LR 6) are more likely. Most examiners auscultate in sequence the second right then the second left intercostal spaces, the left sternal border, and then the apex. The examiner should concentrate on the timing, intensity, and splitting of sounds with respiration. The first and second heart sounds are heard best with the diaphragm, as are pericardial rubs. Gallops (S_3 and S_4) are heard best with the stethoscope bell. High-pitched versus low-pitched murmurs are detected by switching from the diaphragm to the bell. The location, timing, intensity, radiation patterns, and respiratory variation of murmurs should be noted. Special maneuvers during auscultation (e.g., Valsalva, auscultation during sudden squatting or standing) do not usually need to be performed if the results of routine precordial examination are entirely normal.

The presence of an S_3 gallop is useful for detecting left ventricular systolic dysfunction (LR > 4 for identifying patients with an ejection fraction of <30%). The presence of a systolic thrill (palpable murmur, LR 12) or a holosystolic murmur increases the likelihood of moderate to severe aortic stenosis or mitral regurgitation. Quiet systolic murmurs (LR 0.08) are much less likely to herald important cardiac abnormalities. A loud, early diastolic murmur (LR 4) or a diastolic murmur associated with an S_3 suggests severe aortic regurgitation.

Breast

The most important determinants of the accuracy of the breast examination are the duration of the examination; the patient's position; careful evaluation of the breast boundaries; the pattern of the examination; and the position, movement, and pressure of the examiner's fingers (Chapter 198). To obtain the best sensitivity, the duration of the breast examination needs to be 5 to 10 minutes' total time, but few generalist physicians perform such a lengthy examination. Clinicians should recognize that the examination may make them (or their patient) feel uncomfortable—the presence of a chaperone may give the clinician the confidence to perform an intensive examination.

The patient should be examined with the pads of the fingers while she is supine, holding her hand first on her forehead (to flatten the lateral border of the breast) and then on her shoulder (to flatten the medial border). The examiner should make small circular motions with the fingers, moving up and down in parallel rows to span the entire breast-clavicle to the bra line. Cancerous breast lumps are difficult to distinguish from benign breast lumps on examination, but the presence of a fixed mass or a mass 2 cm in diameter has an LR of about 2 to 2.5 for cancer.

Abdomen

When patients have potential abdominal symptoms and the history suggests an acute problem, the examination should focus initially on identifying patients who require surgical evaluation. Palpation and percussion of the abdomen of patients with no symptoms or risk factors for an abdominal disorder seldom reveal important abnormalities (Chapter 132) except for asymptomatic widening of the abdominal aorta in older patients (LR of 16 for detecting aneurysms >4 cm in diameter). However, palpation misses a substantial proportion of small to medium aneurysms (Chapter 78).

The presence of bowel sounds in patients with acute symptoms can be falsely reassuring because the sounds can be present despite an ileus and may be increased early in an obstruction. For patients without gastrointestinal symptoms or abnormalities on palpation, auscultation for bruits is important primarily to detect renal bruits in patients with hypertension (Chapters 67 and 125). The presence of an abdominal bruit in a hypertensive patient, if heard in systole and diastole, strongly suggests renovascular hypertension (LR ≈ 40).

Liver

Detection of liver disease depends mostly on the history and laboratory evaluations (Chapter 146). By the time that signs are present on physical examination, the patient usually has advanced liver disease. The first abnormalities on physical examination associated with liver disease are extrahepatic. The clinician should assess the patient for ascites, peripheral edema, jaundice, or splenomegaly. In patients with an enlarged liver, palpation should begin at the liver edge, but palpation of the edge below the costal margin increases the likelihood of hepatomegaly only slightly (LR 1.7). The upper border of the liver may be detected by percussion, and a span of less than 12 cm reduces the likelihood of hepatomegaly. In the absence of a known diagnosis (e.g., a hepatoma, which may cause a hepatic bruit), auscultation of the liver rarely is helpful.

Spleen

Examination for splenomegaly in patients without findings suggestive of a disorder associated with splenomegaly almost always reveals nothing (Chapter 168). Approximately 3% of healthy teenagers may have a palpable spleen. The examination for an enlarged spleen begins first with percussion in the left upper quadrant to detect dullness. Palpation can be performed by any of the following three approaches ($\kappa \approx 0.2$ to 0.4): palpating with the right hand while providing counterpressure with the left hand behind the spleen, palpating with one hand without counterpressure (with the patient in the right lateral decubitus position for both techniques), or placing the patient supine with the left fist under the left costovertebral angle while the examiner tries to hook the spleen with the hands.

Musculoskeletal System

The musculoskeletal examination in adult patients is almost always driven by symptoms (Chapters 256 and 263). Most patients have back pain at some point during their life (Chapter 400). The patient's history helps assess the likelihood of an underlying systemic disease (age, history of systemic malignancy, unexplained weight loss, duration of pain, responsiveness to previous therapy, intravenous drug use, urinary infection, or fever). The most important physical examination findings for lumbar disc herniation in patients with sciatica all have excellent reliability, including ipsilateral straight leg raising causing pain, contralateral straight leg raising causing pain, and ankle or great toe dorsiflexion weakness.

The generalist physician should evaluate an adult patient with knee discomfort for torn menisci or ligaments. The best maneuver for demonstrating a tear in the anterior cruciate ligament is the anterior drawer or Lachman maneuver, in which the examiner detects the lack of a discrete end point as the tibia is pulled toward the examiner while the femur is stabilized. A variety of maneuvers that assess for pain, popping, or grinding along the joint line between the femur and tibia are used to evaluate for meniscal tears. As with many musculoskeletal disorders, no single finding has the accuracy of the orthopedist's examination, which factors in the history and a variety of clinical findings.

The shoulder examination is directed toward determining range of motion, maneuvers that cause discomfort, and assessment of functional disability.

Hip osteoarthritis is detected by evidence of restriction of internal rotation and abduction of the affected hip. Generalist physicians often rely on radiographs to determine the need for referral to orthopedic physicians, but routine radiographs are not needed early in the course of shoulder or hip disorders. The degree of pain and disability experienced by the patient may prompt confirmation of the diagnosis and referral.

The hands and feet may show evidence of osteoarthritis (local or as part of a systemic process) (Chapter 262), rheumatoid arthritis (Chapter 264), gout (Chapter 273), or other connective tissue diseases. In addition to regional musculoskeletal disorders, such as carpal tunnel syndrome, a variety of medical and neurologic conditions should prompt routine examination of the distal ends of the extremities to prevent complications (e.g., diabetes [neuropathy or ulcers] or hereditary sensorimotor neuropathy [claw toe deformity]).

Skin

The skin should be examined under good lighting (Chapter 436). It is best to ask the patient to point out any spots on the skin of concern. Examiner agreement on some of the most important features of melanoma (asymmetry, haphazard color, border irregularity) is fair to moderate (Chapter 203). A lesion that is symmetrical, has regular borders, is only one color, is 6 mm or smaller, or has not enlarged in size is unlikely to represent a melanoma (LR 0.07). However, an increasing number of findings greatly enhance the likelihood of melanoma (LR 2.6 for two or more findings and LR 98 for the presence of all five findings) (Chapter 203).

Basal cell carcinoma and squamous cell carcinoma occur more frequently than melanoma (Chapter 203). These lesions can be detected during routine examination by paying careful attention to sun-exposed areas of the nose, face, forearms, and hands.

Neurologic Examination

Full details of the neurologic examination are given in Chapter 396.

Psychiatric Evaluation

During the general examination, much of the psychiatric assessment (including cognition) is accomplished while eliciting the routine history and performing the review of systems (Chapter 397). Observation of the patient's mannerisms, affect, facial expression, and behavior may suggest underlying psychiatric disturbances. When a screening survey and review of systems are obtained by a questionnaire completed by the patient, the clinician should review the responses carefully to determine whether the patient exhibits symptoms of depression. Specific questioning for symptoms of depression is appropriate for all adult patients. Military veterans should be screened for post-traumatic stress disorder and possible prior traumatic brain injuries that may affect their behaviors. Delirium (Chapter 28) is common in both medical and surgical inpatients and is recognized by fluctuating mental status. Delirium should be suspected when the patient has trouble carrying on a normal conversation during bedside rounds; but the patient's nurse and visitors may detect delirium before the physician, so their report may contribute to diagnosis.[12]

Genitalia and Rectum

Pelvic Examination

A complete examination includes a description of the external genitalia, appearance of the vagina and cervix as seen through a speculum, and bimanual palpation of the uterus and ovaries (Chapters 199 and 237). About 10 to 15% of asymptomatic women have some abnormality on examination, and 1.5% have abnormal ovaries. However, screening for ovarian cancer is limited by the low sensitivity of the physical examination for detecting early-stage ovarian carcinoma (Chapter 199). In the emergency setting, all women of reproductive age with vaginal bleeding and pelvic pain should have a pregnancy test and an ultrasound to evaluate them for a possible ectopic pregnancy.[13]

Male Genitalia

Examination of the male genitalia should begin with a description of whether the penis is circumcised and whether there are any visible skin lesions (e.g., ulcers or warts). Palpation should confirm the presence of bilateral testes in the scrotum. The epididymis and testes should be palpated for nodules. The low incidence of testicular carcinoma means that most nodules are benign (Chapter 200).

The prostate should be examined in all quadrants, with attention focused on surface irregularities or differences in consistency throughout the prostate (Chapter 201). An estimate of prostate size may be confounded by the size of the examiner's fingers. It may be best to estimate the size of the prostate in centimeters of width and height.

Rectum

Patients can be examined while lying on their side, although this approach may place the examiner in an awkward stance (Chapters 132 and 145). The rectal examination in women can be performed as part of a bimanual examination, with the index finger in the vagina and the third finger in the rectum to permit palpation of the rectovaginal vault. Men may be asked to stand and lean over the examining table; alternatively, they may be examined while on their back with their hips and knees flexed. This latter maneuver is not used often, although it may facilitate examination of the prostate, which falls into the finger in this position.

The rectal examination begins with inspection of the perianal area for skin lesions. A well-lubricated, gloved finger is placed on the anus, and while applying gentle pressure, the examiner asks that the patient bear down as though having a bowel movement. This maneuver facilitates entry of the finger into the rectum. A normal rectal response includes tightening of the anal sphincter around the finger. The examiner should palpate circumferentially around the length of the fully inserted finger for masses. On withdrawing the gloved finger, the finger should be wiped on a stool guaiac card for fecal blood testing to assess for acute blood loss. As a screening test for colorectal carcinoma (Chapter 193), digital examination does not replace the need for testing stool samples collected by the patient (or using alternative screening strategies, such as flexible sigmoidoscopy or colonoscopy).

SUMMARIZING THE FINDINGS FOR THE PATIENT

The physician should summarize the pertinent positive and negative findings for the patient and be willing to express uncertainty to the patient, provided that it is accompanied by a plan of action (e.g., "I will reexamine you on your next visit"). The rationale for subsequent laboratory, imaging, or other tests should be explained. A plan should be established for providing further feedback and results to the patient, especially when there is a possibility that bad news may need to be delivered. Some physicians ask the patient if there is "anything else" to be covered. Patients who express additional new concerns at the end of the visit may have been fearful to address them earlier (e.g., "by the way, doctor, I'm getting a lot of chest pain"); when the problems seem non-urgent, it is acceptable to reassure the patient and offer the promise of evaluating the patient in a follow-up phone call or at the next visit.

FUTURE DIRECTIONS

The common assumption that physicians' diagnostic skills are deteriorating is not supported by evidence. There is considerable evidence that the scientific approach to understanding what is worthwhile and what is not worthwhile during the clinical examination identifies a core set of skills for clinical diagnosticians. Because good patient outcomes at good value are driven primarily by the quality of the information obtained during the clinical examination, continued application of scientific principles to the history and physical examination should improve diagnostic skills.

REVIEW QUESTIONS

1. A 24-year-old-woman with right lower quadrant abdominal pain and vaginal bleeding has a positive home pregnancy. Before a pelvic ultrasound is ordered, the pelvic examination is performed and reveals cervical motion tenderness. Cervical motion tenderness has the following diagnostic characteristics for an ectopic pregnancy: sensitivity 45%, specificity 91%, likelihood ratio positive (LR+) 4.9, LR negative (LR−) 0.62, positive predictive value (PPV) 46%. Which of these values is most helpful for assessing the probability that she has an ectopic pregnancy?

A. Sensitivity
B. Specificity
C. Likelihood ratio positive
D. Likelihood ratio negative
E. Positive predictive value

Answer: C The sensitivity is the percentage of patients who have cervical motion tenderness among women with an ectopic pregnancy. The specificity is the percentage of patients who do not have cervical motion tenderness among women without an ectopic pregnancy. These individual values are not helpful for this particular patient (Crochet JR, Bastian LA, Chireau MV. does this woman have an ectopic pregnancy? The rational clinical examination systematic review. *JAMA*. 2013;309:1722-1729) because without knowing whether or not she has an ectopic pregnancy, we do not know which result applies. The PPV describes the probability of ectopic pregnancy when there is cervical motion tenderness. To use the PPV for this patient requires knowing the prevalence of disease from which the PPV was derived. Without knowing that value, you cannot be certain whether the PPV is appropriate for your patient. The LR+ quantifies the increase in odds of disease among those with cervical motion tenderness, and the LR− quantifies the decrease in odds of disease when cervical motion tenderness is absent. Based on your assessment of the prior probability of ectopic pregnancy, which is 10 to 20% among all pregnant women with abdominal pain and/or vaginal bleeding, the LR+ is the most relevant value because it can be used to determine the increase in likelihood of ectopic pregnancy (Chapter 10).

2. The primary role of completing a review of systems in helping with clinical diagnosis during the clinical evaluation is which of the following?

A. To review symptoms associated with the presenting problem
B. To pick up the presence of concerns that were uncomfortable to address during the history of the present illness
C. To complete a record that enhances patient billing
D. To focus on the presence or absence of findings during a constrained time period
E. To allow open-ended questioning that enhances the patient's relationship with the physician

Answer: D A complete medical history should reveal the most important symptoms experienced by the patient that are pertinent to the presenting problems. Open-ended questioning should occur during elicitation of the medical history. Although completing a review of systems may be required for electronic medical records and billing, simply fulfilling that function does not help with diagnosis. However, about 10% of the time, the review of systems might pick up on an important finding that was not addressed during the rest of the evaluation. The main purpose of the review of systems is to use direct questioning to pick up on a limited set of symptoms, during a specified recent time interval (e.g., over the past week, or the past month). This approach helps the patient focus on a well-defined and recent time period that should enhance the reliability of their answers that pertain to their current condition.

3. While conducting your new patient evaluation on a 35-year-old male veteran who served in combat duty in Afghanistan, you note that he seems anxious and that he is questioning you frequently about a variety of difficulties in making his appointment and the attitudes of your office staff. You recognize the need to screen for post-traumatic stress disorder using a four-item screening instrument. You start by asking, "In your life, have you ever had an experience so horrible, frightening, or upsetting that, in the past month you …" All of the items below are part of the four-item screening instrument for post-traumatic stress disorder that follows this introduction except:

A. Have little interest or pleasure in doing things?
B. Have had nightmares about it or thought about it when you did not want to?
C. Tried hard not to think about it or went out of your way to avoid situations that reminded you of it?
D. Were constantly on guard, watchful, or easily startled?
E. Felt numb or detached from others, activities, or your surroundings?

Answer: A The loss of interest or pleasure in doing things is a symptom that suggests depression. The other symptom that is elicited in a two-item screener for depression asks the patient whether they feel down, depressed, or hopeless (Kroenke K, Spitzer RL, Williams JB. The Patient Health Questionnaire-2: validity of a two-item depression screener. *Med Care*. 2003;41:1284-1292). Patients who answer "yes" to at least one of the items have an LR+ of 2.7 for depression, whereas answering "no" to both questions makes depression much less likely with an LR of 0.14 (Williams JW Jr, Noël P, Cordes JA, et al. Is this patient clinically depressed? *JAMA*. 2002;287:1160-1170). Although it is important to screen for depression among patients with post-traumatic stress disorder (military related or not) (Campbell DG, Felker BL, Liu CF, et al. Prevalence of depression-PTSD comorbidity: implications for clinical practice guidelines and primary care-based interventions. *J Gen Intern Med*. 2007;22:711-718), screening for depression alone may not detect the associated post-traumatic stress disorder.

APPROACH TO THE PATIENT WITH ABNORMAL VITAL SIGNS

DAVID L. SCHRIGER

Care of the patient is guided by integration of the chief complaint, history, vital signs, and physical examination findings (Chapter 7). Physicians should be keenly aware of a patient's vital signs but should seldom make them the centerpiece of the evaluation.

TABLE 8-1 NORMAL AND PANIC RANGES FOR KEY VITAL SIGNS IN ADULTS*

	NORMAL	PANIC
Temperature	36°-38° C (96.8°-100.4° F)	40° C (104° F)
Pulse	60-100 beats/min	<45 beats/min, >130 beats/min
Respirations	12-20 breaths/min	<10 breaths/min, >26 breaths/min
Oxygen saturation	95-100%	<90%
Systolic blood pressure	90-130 mm Hg	<80 mm Hg, >200 mm Hg
Diastolic blood pressure	60-90 mm Hg	<55 mm Hg, >120 mm Hg

*Normal values are for healthy adults. Values outside these ranges are common in patients who are ill or are anxious about their health care encounter. Panic values demand the health care provider's attention in any adult patient. These values are specific (rarely present in healthy patients) but not sensitive (most ill patients' vital signs will not include panic values). All vital signs must be interpreted in the context of the patient's presentation (see text).

THE IMPORTANCE OF VITAL SIGNS

The importance of vital signs in medical care is a conundrum for proponents of an evidence-based approach to the care of patients. No experienced physician would be willing to care for patients without them, yet a formal evaluation of the utility of vital signs for making specific diagnoses would conclude that they are not particularly useful because their likelihood ratios are too close to 1 to differentiate those who have a specific condition from those who do not (Chapter 7). For uncommon conditions, their predictive value is even worse. For example, the probability of tachycardia in a patient in thyroid storm is high, yet the probability of thyroid storm in a patient with isolated tachycardia is low. This application of Bayes theorem (Chapter 10) demonstrates why there is no justification for ordering thyroid tests for every tachycardic patient and why attempts to say "When vital sign *x* is high [low], do *y*" fail. Each vital sign can be normal or abnormal in almost every acute condition (Table 8-1), and vital signs can be transiently abnormal in healthy individuals. An algorithmic approach to testing and treatment in response to abnormal vital signs would be too vague and too complex to be of use.

Predictive Value

How can it be that vital signs are poor predictors of diagnoses but central to the practice of medicine? First, although vital signs are insufficiently predictive to be of use in rigid algorithms, these algorithms are but one of several heuristics used by physicians to diagnose and to treat patients. Pattern recognition and the hypothetical-deductive model are heuristics that are based not on average tendencies of a single factor (e.g., hypotension is present in *x*% of cases of septic shock) or a small number of factors (hypotension and tachycardia are present in *y*% of cases of septic shock) but on the complex interaction of multiple factors (e.g., because this patient is an ill-appearing elderly man with an enlarged prostate and a history of urinary tract infections, is tachycardic and hypotensive, has clear lungs and an enlarged but nontender prostate, and has an oxygen saturation of 97%, he should be treated for urosepsis [Chapter 284] while awaiting results of urinalysis and urine culture). Thus, vital signs can play an important function in medical decision making even though their likelihood ratios for specific conditions are unimpressive.

Despite their poor predictive value for any single diagnosis, abnormal vital signs help identify patients who are sicker.[1] For example, even one abnormal vital sign in the emergency department significantly increases the likelihood of adverse outcomes in elderly patients by about 50%,[2] and abnormal vital signs after admission carry a 20-fold increased risk for subsequent important deterioration.[3] Abnormal vital signs are also a key predictor of which patients are at risk of dying soon after being sent home from an emergency department.[4]

The usefulness of vital signs is also evidenced by the finding that more severe abnormalities are associated with an even worse prognosis. For example, among hospitalized patients, one critically abnormal vital sign carries about a 1% risk for inpatient death, whereas three simultaneously abnormal vital signs carry nearly a 25% risk for inpatient death.[5]

Vital Signs as Symptoms

Abnormal vital signs are seldom the fundamental pathophysiologic problem. In shock (Chapter 106), hypotension and tachycardia are manifestations of pathophysiologic processes occurring at cellular and molecular levels. Given the circuitous links from clinical disease to fundamental pathophysiology to abnormal vital signs, it is not surprising that the relationships between the disease states and vital signs are not strong. Until new technologies enable direct measurement of primary pathologic processes, vital signs remain an important, albeit imperfect, proxy.

The five key vital signs are temperature, pulse, blood pressure, respiratory rate, and oxygen saturation (pulse oximetry). Pulse oximetry is included because it has become widely available in acute care settings, is noninvasive and relatively inexpensive, and provides information unique from the respiratory rate. Advocates have suggested that pain, smoking status, and weight be considered routine vital signs; although a case can be made for each, they are not considered here. Clinicians should never forget that the most important vital sign is what the patient looks like; general appearance is a sign that guides the intensity and urgency of the evaluation.

MEASURING VITAL SIGNS

Although obtaining vital signs is generally straightforward, the validity and reliability of measurement depend on proper technique and, for blood pressure and pulse oximetry, well-maintained equipment. Rectal and oral temperatures are generally accurate (Chapter 280), although oral temperatures can be falsely depressed in patients who breathe through their mouths. Axillary temperature is unreliable and should not be used. There is wide variability in the validity and reliability of measurements performed with tympanic membrane thermometers. A hypothermia thermometer is preferred in patients with suspected hypothermia, and core temperature should be measured with an esophageal, bladder, or rectal temperature sensor in patients with severe hypothermia or hyperthermia (Chapter 109).

Blood pressure must be measured with an appropriately sized cuff (Chapter 67). Automated blood pressure machines occasionally provide spurious results, and questionable values should be confirmed by manual auscultation and by checking other limbs. Pulse is best obtained by palpation because this technique provides the opportunity to assess regularity and contour; the pulse should be counted for sufficient time for an accurate rate to be obtained (at least 15 seconds). High heart rates on the digital readout of a cardiac monitor must be confirmed by palpation because these monitors can spuriously count large P waves, T waves, or pacemaker spikes as R waves, thereby reporting a heart rate double the actual rate. Orthostatic vital signs—the comparison of blood pressure and pulse in the supine, sitting, and standing positions—are advocated by some but have proved to be insensitive and nonspecific for hypovolemia.

Because the typical respiratory rate is between 12 and 20 breaths per minute and because there is considerable breath-to-breath variation, the respiratory rate should be assessed for at least 30 seconds and preferably 1 minute. New technologies purporting to measure the respiratory rate have not proved clinically useful. Oxygen saturation is dependent on technology, so an understanding of the idiosyncrasies of the device being used is critical; valid measurements are unlikely unless there is good correlation of the machine's pulse reading and the patient's pulse. The probe should be placed on a part of the body that is warm and well perfused. Pulse oximeters compare the absorption of light at two wavelengths, so readings may be spuriously high under conditions that change the color of oxygenated or deoxygenated hemoglobin, including carbon monoxide poisoning (Chapter 94), methemoglobinemia (Chapter 161), and some of the less common hemoglobinopathies.

ROLE OF VITAL SIGNS IN MANAGEMENT OF THE PATIENT

Abnormal vital signs should be remeasured. Certain abnormalities require prompt evaluation (Table 8-2). Other vital sign abnormalities should be rechecked in the future unless they have been previously noted, in which case a work-up can be initiated, guided by the patient's past history and physical examination findings. It is critical that the physician always "treat the patient, not the vital signs."

Patients without Systemic Complaints

In patients presenting for a routine evaluation or nonsystemic complaint (e.g., knee injury), an abnormal vital sign will seldom be the harbinger of acute illness. Most commonly, it will be a false reading or a transient finding due to random variation or anxiety that requires no evaluation or treatment and can be rechecked in the future. On occasion, it will be the only or most apparent manifestation of a chronic condition or risk factor. The

TABLE 8-2 ABNORMALITIES REQUIRING RAPID EVALUATION IN THE ASYMPTOMATIC PATIENT

An irregularly irregular rapid pulse (if it is not known to be chronic) should trigger an evaluation of the patient's rhythm so that atrial fibrillation can be identified, evaluated, and treated (Chapter 64), thereby decreasing the patient's risk of stroke.
A heart rate above 130 beats per minute warrants an electrocardiogram to determine the patient's rhythm and a consideration of the differential diagnosis of tachycardia (hypovolemia, anemia, and thyroid disease in particular).
A markedly elevated diastolic blood pressure (e.g., >115 mm Hg) should stimulate an evaluation for hypertensive urgencies (Chapter 67). Note that hypertension in the absence of signs of acute end-organ damage does not require acute treatment, which can reduce intracranial perfusion pressure and cause stroke. Patients with elevated blood pressure should be offered standard evaluation and treatment for chronic hypertension (Chapter 67).
Markedly low pulse or blood pressure in patients receiving cardioactive medications should lead to a confirmation that the patient is truly asymptomatic, an inquiry into the dosing of these medications, and a reconsideration of the regimen.
Markedly low pulse in elderly patients who are not receiving rate-controlling drugs should trigger an evaluation of the patient's cardiac conduction system.
Oxygen saturation below 93% in the absence of known pulmonary problems should prompt an evaluation of the patient's pulmonary status.

measurement of an elevated blood pressure leading to a diagnosis of hypertension is the classic example of the value of vital signs in such patients.

Patients Who Complain of Systemic Illness but Do Not Appear to Be Very Ill

Vital signs serve two additional roles in symptomatic patients who do not appear particularly ill. First, abnormalities in vital signs provide information that may suggest or support a diagnosis. The presence of elevated temperature in a patient with productive cough, shortness of breath, and localized rales and egophony supports a diagnosis of infectious pneumonia. Vital signs may also play a role in defining therapy and triage. For example, guidelines for patients with community-acquired pneumonia (Chapter 97) formally incorporate vital signs.

The second role of vital signs in the stable symptomatic patient is to provide warning that the patient is sicker than he or she appears. For example, the presence of hypotension in a well-appearing patient thought to have pyelonephritis may be an indication of sepsis or hypovolemia. For vital signs to be of use, the physician must be aware of them and must incorporate them explicitly into a thought process that considers the dangerous diagnoses associated with the abnormal vital sign. The physician then must decide whether the likelihood of each potentially dangerous diagnosis is high enough to warrant specific evaluation. Unfortunately, no quick or easy rules differentiate spurious abnormalities that can be ignored from those that should trigger additional testing or treatment. What can be said is that the well-trained physician who is aware of abnormal vital signs and is willing to contemplate a change in treatment or disposition in response to them is less likely to make mistakes.

A few specific points bear mention. First, for most vital signs, "normal" is relative. Blood pressure must be interpreted in the context of the patient. For example, a blood pressure of 88/64 mm Hg may be reasonable for an otherwise healthy, young 50-kg woman but should cause concern in a 90-kg middle-aged man. Similarly, a blood pressure of 128/80 mm Hg would be fine in a 60-year-old man but worrisome in a 34-week pregnant woman. Second, because vital signs are insensitive measures of disease, normal vital signs should not dissuade the physician from pursuing potentially critical diagnoses. For example, young, well-conditioned adults may maintain normal vital signs well into the course of shock.

Use of Vital Signs in Patients Who Appear to Be Ill

For some patients, abnormal vital signs are expected on the basis of their appearance and their symptoms. For patients in extremis, care should proceed according to established guidelines such as Advanced Cardiac Life Support (Chapter 63), Advanced Trauma Life Support, and algorithms for the treatment of shock (Chapters 107 and 108). For other ill-appearing patients, two processes must occur. In one, the physician, armed with knowledge of the differential diagnosis of each abnormal vital sign and the ability to take a thorough history and to perform an appropriate physical examination, narrows the list of potential diagnoses and decides which are of sufficient probability to warrant evaluation. Simultaneously, the physician considers the list of treatment options for all diagnoses associated with the abnormal vital sign and, before establishing a diagnosis, initiates those treatments for which the potential benefit of prompt administration exceeds potential harms. For example, antibiotics for febrile patients at risk for bacterial infection, hydrocortisone for hypotensive patients at risk for hypoadrenalism, and thiamine for hypothermic patients at risk for Wernicke encephalopathy may improve outcome and are unlikely to cause harm even if the patient does not have the suspected condition. Although early presumptive treatment can be life-saving in selected patients, it should not be abused; physicians must avoid knee-jerk responses that can cause harm.

Differential Diagnosis and Treatment Options

Single Abnormal Vital Signs

Because vital signs can be abnormal in virtually any disease process, no differential diagnosis can be encyclopedic. The physician should focus initially on common diseases and diseases that require specific treatment. The thought process should begin with the chief complaint and history and then incorporate information about the vital signs and the remainder of the physical examination.

Multiple Abnormal Vital Signs

Patients who are acutely ill are likely to have several abnormal vital signs. Although certain patterns of abnormal vital signs predominate in specific conditions (e.g., hypotension, tachycardia, and hypothermia in profound sepsis), no pattern can be considered pathognomonic. The physician's goal is to work toward a diagnosis while simultaneously providing treatments whose benefits outweigh potential harms.

Fever is generally accompanied by tachycardia, with the general rule of thumb that the heart rate will increase by 10 beats per minute for every 1° C increase in temperature. The absence of tachycardia with fever is known as pulse-temperature dissociation and has been reported in typhoid fever (Chapter 308), legionnaires disease (Chapter 314), babesiosis (Chapter 353), Q fever (Chapter 327), infection with *Rickettsia* spp (Chapter 327), malaria (Chapter 345), leptospirosis (Chapter 323), pneumonia caused by *Chlamydia* spp (Chapter 318), and viral infections such as dengue fever (Chapter 382), yellow fever (Chapter 381), and other viral hemorrhagic fevers (Chapter 381), although the predictive value of this finding is unknown.

Much can be learned by comparing the respiratory rate with pulse oximetry. Hyperventilation in the presence of high oxygen saturation suggests a central nervous system process or metabolic acidosis rather than a cardiopulmonary process. Low respiratory rates in the presence of low levels of oxygen saturation suggest central hypoventilation, which may respond to narcotic antagonists.

Hypertension and bradycardia in the obtunded or comatose patient are known as the Cushing reflex, a relatively late sign of elevated intracranial pressure. Physicians should strive to diagnose and treat this condition before the Cushing reflex develops.

Approach to Abnormalities of Specific Vital Signs

Elevated Temperature

Normal temperature is often cited as 37° C (98.6° F), but there is considerable diurnal variation and variation among individuals, so 38° C is the most commonly cited threshold for fever. Fever thought to be due to infection should be treated with antipyretics and appropriate antimicrobials (Chapter 280). The importance of early administration of antibiotics to potentially septic patients cannot be overstated (Chapters 280 and 281). Hyperthermia (temperature above 40° C) should be treated with cooling measures such as ice packs, cool misting in front of fans, cold gastric lavage, and, for medication-related syndromes, medications such as dantrolene (Chapter 109). Most hospital anesthesia departments will have a designated kit for the treatment of malignant hyperthermia (Chapters 432 and 434).

Low Temperature

The treatment of hypothermia is guided by its cause (Chapter 109). The body's temperature decreases when heat loss exceeds heat production. Every logically possible mechanism for this phenomenon has been observed. Decreased heat production can result from endocrine hypofunction (e.g., Addison disease [Chapter 227], hypopituitarism [Chapter 224], hypothyroidism [Chapter 226]) and loss of the ability to shiver (e.g., drug-induced or neurologic paralysis or neuromuscular disorders). Malfunction of the hypothalamic regulatory system can be due to hypoglycemia (Chapter 229) and a variety of central nervous system disorders (Wernicke encephalopathy

[Chapter 416], stroke [Chapter 407], tumor [Chapter 189], and trauma [Chapter 399]). Resetting of the temperature set point can occur with sepsis. Increased heat loss can be due to exposure, behavioral and physical disorders that prevent the patient from sensing or responding to cold, skin disorders that decrease its ability to retain heat, and vasodilators (including ethanol). A careful history and physical examination should illuminate which of these possibilities is most likely.

Several considerations are worthy of emphasis. The spine of an obtunded hypothermic patient who is "found down" must be protected and evaluated because paralysis from a fall may have prevented the patient from seeking shelter and may have diminished the ability to produce heat. The physician should not forget to administer antibiotics to patients who may be septic (Chapter 108), thiamine to those who may have Wernicke encephalopathy (Chapter 416), hydrocortisone to those who may be hypoadrenal (Chapter 227), and thyroid hormone to those who may have myxedema coma (Chapter 226). Severely hypothermic patients (Chapter 109) should be treated gently because any stimulation may trigger ventricular dysrhythmias; even in the absence of pulses, cardiopulmonary resuscitation should be used only in patients with ventricular fibrillation or asystole.

Elevated Heart Rate

The rate, rhythm, and electrocardiogram differentiate sinus tachycardia from tachyarrhythmias (Chapters 62 to 65). Tachyarrhythmias can be instigated by conditions that may require specific treatment (e.g., sepsis [Chapter 108], electrolyte disorders [Chapters 116, 117, and 118], endocrine disorders [Chapter 221], and poisonings [Chapters 22 and 110]) before the arrhythmia is likely to resolve. For sinus tachycardia, treatment of the underlying cause is always paramount. Treatments may include antipyretics (for fever); anxiolytics; oral or intravenous fluids (for hypovolemia); nitrates, angiotensin-converting enzyme inhibitors, and diuretics (for heart failure and fluid overload [Chapter 59]); oxygen (for hypoxemia); α-blockers (for stimulant overdose); β-blockers (for acute coronary syndromes [Chapters 72 and 73] or thyroid storm [Chapter 226]); and anticoagulation (for pulmonary embolism [Chapter 98]). Tachycardia is often an appropriate response to a clinical condition and should not be treated routinely unless it is causing or is likely to cause secondary problems.

Low Pulse

Bradycardia can be physiologic (athletes and others with increased vagal tone), due to prescribed cardiac medications (e.g., β-blockers, calcium-channel blockers, digoxin), overdoses (e.g., cholinergics, negative chronotropic agents), disease of the cardiac conducting system, electrolyte abnormalities (severe hyperkalemia), and inferior wall myocardial infarction (Chapters 64 and 73). Asymptomatic patients do not require immediate treatment. The goal of therapy is to produce a heart rate sufficient to perfuse the tissues and alleviate the symptoms (Chapter 63). Overdoses should be treated with specific antidotes (Chapter 110). Endocrine disorders should be treated with replacement therapy. In patients with acute coronary syndrome (Chapter 72), the goal is to restore perfusion and alleviate the ischemia. Patients with profound bradycardia or hypotension may require chronotropic drugs to increase perfusion even if these agents increase myocardial oxygen demand. In normotensive patients with milder bradycardia, chronotropic agents should be used only if symptoms and ischemia cannot be resolved by other means. Atropine is the primary therapy for bradycardia; isoproterenol and cardiac pacing are reserved for those who do not respond (Chapter 63).

Elevated Blood Pressure

Elevated blood pressure does not require acute treatment in the absence of symptoms or signs of end-organ damage (Chapter 67). In patients whose blood pressure is markedly above their baseline, the history and physical examination should assess for the conditions that define "hypertensive emergency": evidence of encephalopathy, intracranial hemorrhage, ischemic stroke, heart failure, pulmonary edema, acute coronary syndrome, aortic dissection, renal failure, and preeclampsia. In the absence of these conditions, treatment should consist of restarting or adjusting the medications of patients with known hypertension and initiating a program of blood pressure checks and appropriate evaluation for those with no prior history of hypertension (Chapter 67).

The patient with a true hypertensive emergency should be treated with agents appropriate for the specific condition. Because rapid decreases in blood pressure can be as deleterious as the hypertensive state itself, intravenous agents with short half-lives, such as nitroprusside, labetalol, nitroglycerin, and esmolol, are preferred (Chapter 67).

Low Blood Pressure

Low blood pressure must be evaluated in the context of the patient's symptoms, general appearance, and physical examination findings. Treatment depends on context. The same blood pressure value may necessitate intravenous inotropic agents in one patient and no treatment in another.

In tachycardic hypotensive patients, the physician must rapidly integrate all available evidence to determine the patient's volume state, cardiac function, vascular capacitance, and primary etiology (Chapter 106). Not all patients with hypotension and tachycardia are in shock, and not all patients in shock will have hypotension and tachycardia. Patients in shock should be treated on the basis of the cause (Chapters 106 to 108).

Symptomatic hypotensive patients thought to be intravascularly volume depleted should receive intravenous fluid resuscitation with crystalloid or blood, depending on their hemoglobin level (Chapter 106). In patients with known heart disease, patients who are frail or elderly, and patients whose volume status is uncertain, small boluses of fluid (e.g., 250 mL of normal saline), each followed by reassessment, are preferred so that iatrogenic heart failure may be avoided. Inotropic support should be reserved for patients who do not respond to fluid resuscitation. High-output heart failure should be kept in mind in patients with possible thyroid storm or stimulant overdose.

Increased Respiratory Rate

Tachypnea is a normal response to hypoxemia (see later). Treatment of tachypnea in the absence of hypoxemia is directed at the underlying cause, which often is pain (Chapter 30). Anxiolytics (e.g., diazepam, 5 to 10 mg PO or IV; lorazepam, 1 to 2 mg PO, IM, or IV) or reassurance can calm patients with behavioral causes of hyperventilation. Breathing into a paper bag has been shown to be an ineffective treatment. Pulmonary embolism (Chapter 98) does not necessarily reduce the oxygen saturation or cause a low P_{O_2} and should always be considered in at-risk patients with unexplained tachypnea.

Decreased Respiratory Rate

Any perturbation of the respiratory center in the central nervous system can slow the respiratory drive (Chapter 86). Narcotics and other sedatives and neurologic conditions are common causes of a decreased respiratory rate. The primary treatment of apnea is mechanical ventilation (Chapter 105), but narcotic antagonists can be tried in patients with a history or physical examination findings (miosis, track marks, opiate patch) suggestive of narcotic use or abuse (Chapter 34). In nonapneic patients, mechanical ventilation is indicated for patients who are breathing too slowly to maintain an acceptable oxygen saturation and for patients who are retaining carbon dioxide in quantities sufficient to depress mental function. Patients who are unable to protect their airway should be intubated. Oxygen should be administered to all hypopneic patients who are hypoxemic (see earlier). Patients with chronic hypoventilation (Chapter 86) may have retained HCO_3^- to compensate for an elevated P_{CO_2} and so may depend on hypoxia to maintain respiratory drive; in these patients, overaggressive administration of oxygen can decrease the respiratory rate, increase the P_{CO_2}, and increase obtundation (Chapter 104).

Decreased Oxygen Saturation

In hypopneic patients, initial efforts should try to increase the respiratory rate (see earlier) and tidal volume. Regardless of etiology, oxygen, in amounts adequate to restore adequate oxygen saturation (P_{O_2} > 60 mm Hg, oxygen saturation >90%), is the mainstay of therapy. When oxygen alone fails, noninvasive methods for improving ventilation or tracheal intubation are required (Chapter 104). Oxygen should increase the P_{O_2} in all patients except those who have severe right-to-left shunting (Chapter 69). Treatment of conditions that cause hypoxemia includes antibiotics (pneumonia), bronchodilators (asthma, chronic obstructive pulmonary disease), diuretics and vasodilators (pulmonary edema), anticoagulants (pulmonary embolism), hyperbaric oxygen (carbon monoxide poisoning), methylene blue (methemoglobinemia, sulfhemoglobinemia), and transfusion (anemia).

REVIEW QUESTIONS

1. A patient presents with malaise, cough, and shortness of breath. Vital signs include temperature 40° C, blood pressure 120/74 mm Hg, respiratory rate 18 breaths per minute, pulse 70 beats per minute, and oxygen saturation 97%. This presentation could be consistent with:

A. Streptococcal pneumonia
B. Pyelonephritis due to *Escherichia coli*
C. Legionella pneumonia
D. Influenza-like illness
E. Mycoplasma pneumonia

Answer: C This patient is exhibiting a pulse-temperature dissociation because the pulse (70) is far lower than one would expect given that the patient is febrile to 40° C. This phenomenon is seen in a number of conditions, including typhoid fever and legionella infection. The other conditions would all be expected to produce tachycardia unless the patient could not become tachycardic because of medications (e.g., β-blockers) or cardiac conduction problems.

2. An 88-year-old man presents from a nursing home with slight agitation and vital signs that include temperature 38.7° C, blood pressure 96/64 mm Hg, respiratory rate 22 breaths per minute, pulse 94 beats per minute, and oxygen saturation 96%. Physical examination reveals dry mucous membranes, clear lungs, a soft abdomen, an indwelling Foley catheter, and slightly cool but noncyanotic extremities. The patient should be given:

A. Antipyretics (e.g., acetaminophen)
B. Intravenous normal saline, 500 mL with additional boluses as tolerated
C. Intravenous antibiotics
D. All of the above
E. Only A and B until urine culture results are available

Answer: D This case is an example of how vital signs can guide treatment in the absence of a firm diagnosis. The patient meets all three of the physical examination criteria for the systemic inflammatory response syndrome (SIRS) and is likely septic. The physician should not wait for his white blood cell count or other laboratory results to initiate antibiotic treatment because evidence suggests that early antibiotics are a crucial step in preventing morbidity and mortality. Although antibiotics should not be overused, the early provision of appropriate broad-spectrum antibiotics before the confirmation of a specific diagnosis is prudent and may be life-saving for this patient.

3. An intern is awakened at 3 AM by the ward nurse regarding a patient who is postoperative day 2 from a hip replacement and is newly tachycardic. Vital signs include temperature 36° C, blood pressure 146/82 mm Hg, respiratory rate 18 breaths per minute, pulse 112 beats per minute, and oxygen saturation 97% on room air. The intern drowsily orders a 1000-mL normal saline fluid challenge for dehydration. Later that morning, the patient is acutely intubated for respiratory distress. What most likely went wrong?

A. The intern failed to consider pulmonary embolism as a possible cause for the tachycardia.
B. The intern failed to consider fat embolism in a patient who had recently undergone hip surgery.
C. The intern failed to consider sepsis in the differential diagnosis.
D. The intern failed to consider failure of the patient controlled anesthesia (PCA) pump in the differential diagnosis.
E. The intern failed to realize that tachycardia can be present in both dehydration and heart failure.

Answer: E First and foremost, the intern's main mistake was not getting out of bed to evaluate the patient in person. Vital signs alone are not sufficient data on which to base an important clinical decision. Although choices A and B are certainly possible in a postoperative orthopedic patient, heart failure is a more likely diagnosis. There is little clinical support for the other choices.

4. A patient arrives in the emergency department comatose with decreased respiratory rate in the winter. Vital signs are temperature 36° C, blood pressure 128/68 mm Hg, respiratory rate 10 breaths per minute, pulse 100 beats per minute, and oxygen saturation 100% on room air. Pupils are 6 mm and reactive, and lungs are clear. What is the single most important initial treatment?

A. High-flow O_2 administered by non-rebreather mask
B. Intravenous normal saline, 1000 mL with additional boluses as tolerated
C. Intravenous antibiotics
D. Naloxone, 0.8 mg IV
E. Immediate endotracheal intubation

Answer: A This patient may have carbon monoxide poisoning. It is winter, a time when people use heating devices that may have incomplete combustion. The pupillary examination is not suggestive of opiate intoxication (D), and no other diagnosis is apparent. Because oxygen is the best treatment for this condition and is generally harmless in adults, it makes sense to initiate this therapy while efforts (e.g., blood gas analysis with co-oximetry) are made to confirm the diagnosis. There is no basis for thinking this patient is dehydrated (B) or infected (C), and intubation would be premature (E). Remember that pulse oximetry is falsely elevated in carbon monoxide poisoning, so the 100% oxygen saturation means nothing.

9 STATISTICAL INTERPRETATION OF DATA

THOMAS B. NEWMAN AND CHARLES E. MCCULLOCH

ROLE AND LIMITATIONS OF STATISTICS

Much of medicine is inherently probabilistic. Not everyone with hypercholesterolemia who is treated with a statin is prevented from having a myocardial infarction, and not everyone not treated does have one, but statins reduce the *probability* of a myocardial infarction in such patients. Because so much of medicine is based on probabilities, studies must be performed on *groups* of people to estimate these probabilities. Three component tasks of statistics are: selecting a sample of subjects for study, describing the data from that sample, and drawing inferences from that sample to a larger population of interest.[1]

SAMPLING: SELECTING SUBJECTS FOR A STUDY

The goal of research is to produce generalizable knowledge, so that measurements made by researchers on samples of individuals will eventually help draw inferences to a larger group of people than was studied. The ability to draw such inferences depends on how the subjects for the study (the sample) were selected. To understand the process of selection, it is helpful to begin by identifying the group to which the results are to be generalized and then work backward to the sample of subjects to be studied.

Target Population

The *target population* is the population to which it is hoped the results of the study will be generalizable. For example, to study the efficacy of a new drug to treat obesity, the target population might be all people with a certain level of obesity (e.g., body mass index [BMI] of ≥30 kg/m^2) who might be candidates for the drug.

Sampling

The *intended sample* is the group of people who are eligible to be in the study based on meeting *inclusion criteria,* which specify the demographic, clinical, and temporal characteristics of the intended subjects, and not meeting *exclusion criteria,* which specify the characteristics of subjects whom the investigator does not wish to study. For example, for the study of a new obesity drug, the intended sample (inclusion criteria) might be men and women 18 years or older who live in one of four metropolitan areas, who have a BMI of 30 kg/m^2 or higher, and who have failed an attempt at weight loss with a standard diet. Exclusion criteria might include an inability to speak English or Spanish, known alcohol abuse, plans to leave the area in the next 6 months, and being pregnant or planning to become pregnant in the next 6 months.

In some cases, particularly large population health surveys such as the National Health and Nutrition Examination Survey (NHANES), the intended sample is a *random* sample of the target population. A *simple random sample* is a sample in which every member of the target population has an equal chance of being selected. Simple random samples are the easiest to handle statistically but are often impractical. For example, if the target population is the entire population of the United States (as is the case for NHANES), a simple random sample would include subjects from all over the country. Getting subjects from thousands of distinct geographic areas to examination sites would be logistically difficult. An alternative, used in NHANES, is *cluster* sampling, in which investigators take a random sample of "clusters" (e.g., specific census tracts or geographic areas) and then try to study all or a sample of the subjects in each cluster. Knowledge of the cluster sampling process must then be used during analysis of the study (see later) to draw inferences correctly back to the target population.

Regardless of the method used to select the intended sample, the *actual sample* will almost always differ in important ways because not all intended subjects will be willing to enroll in the study and not all who begin a study will complete it. In a study on treatment of obesity, for example, those who consent to be in the study probably differ in important, but difficult-to-quantify ways from those who do not (and may be more likely to do well with treatment). Furthermore, subjects who respond poorly to treatment may drop out, thus making the group that completes the study even less representative.

Statistical methods address only some of the issues involved in making inferences from a sample to a target population. Specifically, *most statistical methods address only the effect of random variation on the inference from the intended sample to the target population.* Estimating the effects of differences between the intended sample and the actual sample depends on the quantities being estimated and content knowledge about whether factors associated with being in the actual sample are related to those quantities. One rule of thumb about generalizability is that *associations between variables* are more often generalizable than measurements of single variables. For instance, subjects who consent to be in a study of obesity may be more motivated than average, but this motivation would be expected to have less effect on the *difference* in weight loss between groups than on the average weight loss in either group.

DESCRIBING THE SAMPLE

Types of Variables

A key use of statistics is to describe sample data. Methods of description depend on the *type of variable* (E-Table 9-1). *Numerical* variables include *continuous* variables (those that have a wide range of possible values), *count* variables (e.g., the number of times a woman has been pregnant), and *time-to-event* variables (e.g., the time from initial treatment to recurrence of breast cancer). Whereas *numerical* variables describe the data with numbers, *categorical* variables consist of named characteristics. Categorical variables can be further divided into *dichotomous* variables, which can take on only two possible values (e.g., alive/dead); *nominal* variables, which can take on more than two values but have no intrinsic ordering (e.g., race); and *ordinal* variables, which have more than two values and an intrinsic ordering of the values (e.g., tumor stage). Numerical variables are also ordinal by nature and can be made binary by breaking the values into two disjointed categories (e.g., systolic blood pressure >140 mm Hg or not), and thus sometimes methods designed for ordinal or binary data are used with numerical variable types, often for ease of interpretation.

Univariate Statistics for Numerical Variables: Mean, Standard Deviation, Median, and Percentiles

When describing data in a sample, it is a good idea to begin with *univariate* (one variable at a time) statistics. For numerical variables, univariate statistics typically measure *central tendency* and *variability.* The most common measures of central tendency are the *mean* (or average, i.e., the sum of the observations divided by the number of observations) and the *median* (the 50th percentile, i.e., the value that has equal numbers of observations above and below it).

One of the most commonly used measures of variability is the *standard deviation* (SD). The SD is defined as the square root of the *variance,* which is calculated by subtracting each value in the sample from the mean, squaring that difference, totaling all of the squared differences, and dividing by the number of observations minus 1. Although this definition is far from intuitive, the SD has some useful mathematical properties, namely, that if the distribution of the variable is the familiar bell-shaped, *normal,* or *Gaussian* distribution, about 68% of the observations will be within 1 SD of the mean, about 95% within 2 SD, and about 99.7% within 3 SD. Even when the distribution is not normal, these rules are often approximately true.

For variables that are not normally distributed, including most count and time-to-event variables, the mean and SD are not as useful for summarizing the data. In that case, the median may be a better measure of central tendency because it is not influenced by observations far below or far above the center. Similarly, the range and pairs of percentiles, such as the 25th and 75th percentiles or the 15th and 85th percentiles, will provide a better description of the spread of the data than the SD will. The 15th and 85th percentiles are particularly attractive because they correspond, in the Gaussian distribution, to about −1 and +1 SD from the mean, thus making reporting of the 50th, 15th, and 85th percentiles roughly equivalent to reporting the mean and SD.

Univariate Statistics for Categorical Variables: Proportions, Rates, and Ratios

For categorical variables, the main univariate statistic is the *proportion* of subjects with each value of the variable. For dichotomous variables, only one proportion is needed (e.g., the proportion female); for nominal variables and ordinal variables with few categories, the proportion in each group can be provided. Ordinal variables with many categories can be summarized by

E-TABLE 9-1 TYPES OF VARIABLES AND COMMONLY USED STATISTICAL METHODS

		ASSOCIATED STATISTICAL METHODS	
TYPE OF OUTCOME VARIABLE	**EXAMPLES**	**BIVARIATE**	**MULTIVARIATE**
Categorical (dichotomous)	Alive; readmission to the hospital within 30 days	2×2 table, chi-square analysis	Logistic regression
Categorical (nominal)	Race; cancer, tumor type	Chi-square analysis	Nominal logistic regression
Categorical (ordinal)	Glasgow Coma Scale	Mann-Whitney-Wilcoxon, Kruskal-Wallis	Ordinal logistic regression
Numerical (continuous)	Cholesterol; SF-36 scales*	*t* Test, analysis of variance	Linear regression
Numerical (count)	Number of times pregnant; number of mental health visits in a year	Mann-Whitney-Wilcoxon, Kruskal-Wallis	Poisson regression, linear models
Time to event regression	Time to breast cancer; time to viral rebound in HIV-positive subjects	Log rank	Cox proportional hazards

*Numerical scores with many values are often treated as though they were continuous. HIV = human immunodeficiency virus; SF-36 = short-form 36-item health survey.

using proportions or by using medians and percentiles, as with continuous data that are not normally distributed.

It is worth distinguishing among *proportions, rates,* and *ratios* because these terms are often confused. *Proportions* are unitless, always between 0 and 1 inclusive, and express what fraction of the subjects have or develop a particular characteristic or outcome. Strictly speaking, *rates* have units of inverse time; they express the proportion of subjects in whom a particular characteristic or outcome develops over a specific time period. The term is frequently misused, however. For example, the term *false-positive rate* is widely used for the proportion of subjects without a disease who test positive, even though it is a proportion, not a rate. *Ratios* are the quotients of two numbers; they can range between zero and infinity. For example, the male-to-female ratio of people with a disease might be 3 : 1. As a rule, if a ratio can be expressed as a proportion instead (e.g., 75% male), it is more concise and easier to understand.

Incidence and Prevalence

Two terms commonly used (and misused) in medicine and public health are *incidence* and *prevalence. Incidence* describes the number of subjects who *contract* a disease *over time* divided by the population at risk. Incidence is usually expressed as a rate (e.g., 7 per 1000 per year), but it may sometimes be a proportion if the time variable is otherwise understood or clear, as in the lifetime incidence of breast cancer or the incidence of diabetes during pregnancy. *Prevalence* describes the number of subjects who *have* a disease at *one point in time* divided by the population at risk; it is always a proportion. At any point in time, the prevalence of disease depends on how many people contract it and how long it lasts: prevalence = incidence × duration.

Bivariate Statistics

Bivariate statistics summarize the relationship between two variables. In clinical research, it is often desirable to distinguish between *predictor* and *outcome variables.* Predictor variables include treatments received, demographic variables, and test results that are thought possibly to predict or cause the *outcome variable,* which is the disease or (generally bad) event or outcome that the test should predict or treatment prevent. For example, to see whether a bone mineral density measurement (the predictor) predicts time to vertebral fracture (the outcome), the choice of bivariate statistic to assess the association of outcome with predictor depends on the types of predictor and outcome variables being compared.

Dichotomous Predictor and Outcome Variables

A common and straightforward case is when both predictor and outcome variables are dichotomous, and the results can thus be summarized in a 2 × 2 table. Bivariate statistics are also called *measures of association* (E-Table 9-2).

Relative Risk

The *relative risk* or *risk ratio* (RR) is the ratio of the proportion of subjects in one group in whom the outcome develops divided by the proportion in the other group in whom it develops. It is a general (but not universal) convention to have the outcome be something bad and to have the numerator be the risk for those who have a particular factor or were exposed to an intervention. When this convention is followed, an RR greater than 1 means that exposure to the factor was (on average) bad for the study subjects (with respect to the outcome being studied), whereas an RR less than 1 means that it was good. That is, risk factors that cause diseases will have RR values greater than 1, and effective treatments will have an RR less than 1. For example, in the Women's Health Initiative (WHI) randomized trial, conjugated equine estrogen use was associated with an increased risk for stroke (RR = 1.37) and decreased risk for hip fracture (RR = 0.61).

Relative Risk Reduction

The *relative risk reduction* (RRR) is 1 − RR. The RRR is generally used only for effective interventions, that is, interventions in which the RR is less than 1, so the RRR is generally greater than 0. In the aforementioned WHI example, estrogen had an RR of 0.61 for hip fracture, so the RRR would be 1 − 0.61 = 0.39, or 39%. The RRR is commonly expressed as a percentage and used only when it is positive.

Absolute Risk Reduction

The *risk difference* or *absolute risk reduction* (ARR) is the difference in risk between the groups, defined as earlier. In the WHI, the risk for hip fracture was 0.11% per year with estrogen and 0.17% per year with placebo. Again, conventionally the risk is for something bad, and the risk in the group of interest is subtracted from the risk in a comparison group, so the ARR will be positive for effective interventions. In this case, the ARR = 0.06% per year, or 6 in 10,000 per year.

Number Needed to Treat

The *number needed to treat* (NNT) is 1/ARR. To see why this is the case, consider the WHI placebo group and imagine treating 10,000 patients for a year. All but 17 would not have had a hip fracture anyway because the fracture rate in the placebo group was 0.17% per year, and 11 subjects would sustain a fracture despite treatment because the fracture rate in the estrogen group was 0.11% per year. Thus, with treatment of 10,000 patients for a year, 17 − 11 = 6 fractures prevented, or 1 fracture prevented for each 1667 patients treated for 1 year. This calculation is equivalent to 1/0.06% per year.

Risk Difference

When the treatment *increases* the risk for a bad outcome, the difference in risk between treated and untreated patients should still be calculated, but it is usually just called the risk difference rather than an ARR (because the "reduction" would be negative). In that case, the NNT is sometimes called the number needed to harm. This term is a bit of a misnomer. The reciprocal of the risk difference is still a number needed to treat; it is just a number needed to treat per person harmed rather than a number needed to treat per person who benefits. In the WHI, treatment with estrogens was estimated to cause about 12 additional strokes per 10,000 women per year, so the number needed to be treated for 1 year to cause a stroke was about 10,000/12, or 833.

Odds Ratio

Another commonly used measure of association is the *odds ratio* (OR). The OR is the ratio of the *odds* of the outcome in the two groups, where the definition of the odds of an outcome is $p/(1-p)$, with p being the probability of the outcome. From this definition it is apparent that when p is very small, $1-p$ will be close to 1, so $p/(1-p)$ will be close to p, and the OR will closely approximate the RR. In the WHI, the ORs for stroke (1.37) and fracture (0.61) were virtually identical to the RRs because both stroke and fracture were rare. When p is not small, however, the odds and probability will be quite different, and ORs and RRs will not be interchangeable.

Absolute versus Relative Measures

RRRs are usually more generalizable than ARRs. For example, the use of statin drugs is associated with about a 30% decrease in coronary events in a wide variety of patient populations (Chapter 206). The ARR, however, will usually vary with the baseline risk, that is, the risk for a coronary event in the absence of treatment. For high-risk men who have already had a myocardial infarction, the baseline 5-year risk might be 20%, which could be reduced to 14% with treatment, an ARR of 6%, and an NNT of about 17 for approximately 5 years. Conversely, for a 45-year-old woman with a high low-density lipoprotein cholesterol level but no history of heart disease, in whom the 5-year risk might be closer to 1%, the same RRR would give a 0.7% risk with treatment, a risk difference of 0.3%, and an NNT of 333 for 5 years.

The choice of *absolute* versus *relative measures* of association depends on the intended use of the measure. As noted earlier, RRs are more useful as summary measures of effect because they are more often generalizable across a wide variety of populations. RRs are also more helpful for understanding causality. However, absolute risks are more important for questions about clinical decision making because they relate directly to the tradeoffs between risks and benefits—specifically, the NNT, as well as the costs and side effects that need to be balanced against potential benefits. RRRs are often used in advertising because they are generally more impressive than ARRs. Unfortunately, the distinction between relative and absolute risks may not be appreciated by clinicians, thereby leading to higher estimates of the potential benefits of treatments when RRs or RRRs are used.

Risk Ratios versus Odds Ratios

The choice between RRs and ORs is easier: RRs are preferred because they are easier to understand. Because ORs that are not equal to 1 are always farther from 1 than the corresponding RR, they may falsely inflate the perceived importance of a factor. ORs are, however, typically used in two circumstances. First, in case-control studies (Chapter 11), in which subjects with and without the disease are sampled separately, the RR cannot be

E-TABLE 9-2 COMMONLY USED MEASURES OF ASSOCIATION FOR DICHOTOMOUS PREDICTOR AND OUTCOME VARIABLES*

	OUTCOME		
PREDICTOR	***Yes***	***No***	***Total***
Yes	a	b	**a + b**
No	c	d	**c + d**
Total	**a + c**	**b + d**	***N***
Risk ratio or relative risk (RR)	$\frac{a}{(a+b)} \div \frac{c}{(c+d)}$		
Relative risk reduction (RRR)	1 – RR		
Risk difference or absolute risk reduction (ARR)	$\frac{a}{(a+b)} - \frac{c}{(c+d)}$		
Number needed to treat (NNT)	$\frac{1}{ARR}$		
Odds ratio (OR)	$\frac{ad}{bc}$		

*The numbers of subjects in each of the cells are represented by a, b, c, and d. Case-control studies allow calculation of only the odds ratio.

calculated directly. This situation does not usually cause a problem, however, because case-control studies are generally performed to assess rare outcomes, for which the OR will closely approximate the RR. Second, in observational studies that use a type of multivariate analysis called *logistic regression* (see later), use of the OR is convenient because it is the parameter that is modeled in the analysis.

Dichotomous Predictor Variable, Continuous Outcome Variable

Many outcome variables are naturally continuous rather than dichotomous. For example, in a study of a new treatment of obesity, the outcome might be change in weight or BMI. For a new diuretic, the outcome might be change in blood pressure. For a palliative treatment, the outcome might be a quality-of-life score calculated from a multi-item questionnaire. Because of the many possible values for the score, it may be analyzed as a continuous variable. In these cases, dichotomizing the outcome leads to loss of information. Instead, the *mean difference* between the two groups is an appropriate measure of the effect size. When the outcome is itself a difference (e.g., change in blood pressure over time), the effect is measured by the difference in the *within*-group differences *between* the groups.

Most measurements have units (e.g., kg, mm Hg), so differences between groups will have the same units and be meaningless without them. If the units of measurement are familiar (e.g., kg or mm Hg), the difference between groups will be meaningful without further manipulation. For measurements in unfamiliar units, such as a score on a new quality-of-life instrument, some benchmark is useful to help judge whether the difference between groups is large or small. In that case, authors typically express the difference in relation to the spread of values in the study by calculating the *standardized mean difference* (SMD), which is the difference between the two means divided by the SD of the measurement. It is thus expressed as the number of SDs by which the two groups are apart. To help provide a rough feel for this difference, a 1-SD difference between means (SMD = 1) would be a 15-point difference in IQ scores, a 600-g difference in birthweight, or a 40-mg/dL difference in total cholesterol levels.

Continuous Predictor Variable

When predictor variables are continuous, the investigator can either group the values into two or more categories and calculate mean differences or SMDs between the groups as discussed earlier or use a *model* to summarize the degree to which changes in the predictor variable are associated with changes in the outcome variable. Use of a model may more compactly describe the effects of interest but involves assumptions about the way the predictor and outcome variables are related. Perhaps the simplest model is to assume a linear relationship between the outcome and predictor. For example, one could assume that the relationship between systolic blood pressure (mm Hg) and salt intake (g/day) was linear over the range studied:

$$\mathrm{SBP}_i = a + (b \times \mathrm{SALT}_i) + \varepsilon_i$$

where SBP_i is the systolic blood pressure for study subject *i*, SALT_i is that subject's salt intake, and ε_i is an error term that the model specifies must average out to zero across all of the subjects in the study. In this model, *a* is a constant, the *intercept,* and the strength of the relationship between the outcome and predictor can be summarized by the slope *b,* which has units equal to the units of SBP divided by the units of SALT, or mm Hg per gram of salt per day in this case.

Note that without the units, such a number is meaningless. For example, if salt intake were measured in grams per week instead of grams per day, the slope would only be one seventh as large. Thus, when reading an article in which the association between two variables is summarized, it is critical to note the units of the variables. As discussed earlier, when units are unfamiliar, they are sometimes standardized by dividing by the SDs of one or both variables.

It is important to keep in mind that use of a model to summarize a relationship between two variables may not be appropriate if the model does not fit. In the preceding example, the assumption is that salt intake and blood pressure have a linear relationship, with the slope equal to *b* mm Hg/g salt per day. The value of *b* is about 1 mm Hg/g salt per day for hypertensive patients. If the range of salt intake of interest is from 1 to 10 g/day, the model predicts that blood pressure will increase 1 mm Hg as a result of a 1-g/day increase in salt intake whether that increase is from 1 to 2 g/day or from 9 to 10 g/day. If the effect of a 1-g/day change in salt intake differed in subjects ingesting low- and high-salt diets, the model would not fit, and misleading conclusions could result.

When the outcome variable is dichotomous, the relationship between the probability of the outcome and a continuous predictor variable is often modeled with a *logistic* model:

$$\Pr\{Y_i = 1\} = \frac{1}{1 + e^{-(a + bx_i)}}$$

where the outcome Y_i is coded 0 or 1 for study subject *i,* and x_i is that subject's value of the predictor variable. Once again, *a* is a constant, in this case related to the probability of the disease when the predictor is equal to zero, and *b* summarizes the strength of the association; in this case, it is the natural logarithm of the OR rather than the slope. The OR is the OR *per unit change* in the predictor variable. For example, in a study of lung cancer, an OR of 1.06 for pack years of smoking would indicate that the odds of lung cancer increase by 6% for each pack year increase in smoking.

Because the outcome variable is dichotomous, it has no units, and "standardizing" it by dividing by its SD is unnecessary and counterproductive. On the other hand, continuous predictor variables do have units, and the OR for the logistic model will be per unit change in the predictor variable or, if standardized, per SD change in the predictor variable. Re-expressing predictors in standardized or at least more sensible units is often necessary. For example, suppose 10-year mortality risk decreases by 20% (i.e., RR = 0.8) for each increase in gross income of $10,000. The RR associated with an increase in gross income of $1 (which is what a computer program would report if the predictor were entered in dollars) would be 0.99998, apparently no effect at all because a change of $1 in gross income is negligible and associated with a negligible change in risk. To derive the coefficient associated with a $1 change, the coefficient for a $10,000 change is raised to the $^{1}/_{10,000}$ power: $0.8^{(1/10{,}000)} = 0.99998$.

Multivariable Statistics

In many cases, researchers are interested in the effects of multiple predictor variables on an outcome. Particularly in observational studies, in which investigators cannot assign values of a predictor variable experimentally, it will be of interest to estimate the effects of a predictor variable of interest *independent* of the effects of other variables. For example, in studying whether breastfeeding reduces the mother's risk for subsequent breast cancer, investigators would try to take differences in age, race, family history, and parity into account. Trying to stratify by all these variables would require a massive data set. Instead, models are used because they enable the information about individual predictors to be summarized by using the full data set. In this way, the estimated coefficients from the model are powerful descriptive statistics that allow a sense of the data in situations in which simpler methods fail. These models are similar to those described earlier but include terms for the additional variables.

Multiple Linear Regression

The multiple linear regression model for an outcome variable Y as function or predictor variables x_1, x_2, and so forth is as follows:

$$Y_i = a + (b_1 \times x_{1i}) + (b_2 \times x_{2i}) + \ldots + (b_k \times x_{ki}) + \varepsilon_i,$$

where the subscripts 1, 2, …, k are for the first, second, … k^{th} variables of the model, and the *i* subscripts are for each individual. As before, the relationships between each of these predictor variables and the outcome variable are summarized by coefficients, or slopes, which have units of Y divided by the units of the associated predictor. In addition, the linear combination of predictor variables adds a major simplifying constraint (and assumption) to the model: it specifies that the effects of each variable on the outcome variable are the same regardless of the values of other variables in the model. Thus, for example, if x_1 is the variable for salt intake and x_2 is a variable for sex (e.g., 0 for females and 1 for males), this model assumes that the average effect of a 1-g increase in daily salt intake on blood pressure is the same in men and women. If such is not believed to be the case, either based on previous information or from examining the data, the model should include *interaction* terms, or separate models should be used for men and women.

Multiple Logistic Regression

The logistic model expands to include multiple variables in much the same way as the linear model:

$$\Pr\{Y_i = 1\} = \frac{1}{1 + e^{-(a + b_1 i + b_2 x_{2i} + \ldots + b_k x_{ki})}}$$

Again, the additional assumption when more than one predictor is included in the model is that in the absence of included interaction terms,

the effect of each variable on the odds of the outcome is the same regardless of the values of other variables in the model. Because the logistic model is multiplicative, however, the effects of different predictors on the odds of the outcome are multiplied, not added. Thus, for example, if male sex is associated with a doubling of the odds for heart disease, this doubling will occur in both smokers and nonsmokers; if smoking triples the odds, this tripling will be true in both men and women, so smoking men would be predicted to have $2 \times 3 = 6$ times higher odds of heart disease than nonsmoking women.

Recursive Partitioning

Recursive partitioning, or "*classification and regression trees,*" is a prediction method often used with dichotomous outcomes that avoids the assumptions of linearity. This technique creates prediction rules by repeatedly dividing the sample into subgroups, with each subdivision being formed by further separating the sample on the value of one of the predictor variables. The optimal choice of variables and cut points may depend on the relative costs of false-positive and false-negative predictions, as set by the investigator. The end result is a set of branching questions that forms a treelike structure in which each final branch provides a yes/no prediction of the outcome. The methods of fitting the tree to data (e.g., cross-validation) help reduce overfitting (inclusion of unnecessary predictor variables), especially in cases with many potential predictors.

Proportional Hazards (Cox) Model

A multivariate model often used in studies in which subjects are monitored over time for development of the outcome is the *Cox* or *proportional hazards* model. Like the logistic model, the Cox model is used for continuous or dichotomous predictor variables, but in this case with a time-to-event outcome (e.g., time to a stroke). This approach models the *rate* at which the outcome occurs over time by taking into account the number of people still at risk at any given time. The coefficients in the Cox model are logarithms of *hazard ratios* rather than ORs, interpretable (when exponentiated) as the effect of a unit change in predictors on the *hazard* (risk in the next short time period) of the outcome developing. Like the logistic model, the Cox model is multiplicative; that is, it assumes that changes in risk factors multiply the hazard by a fixed amount regardless of the levels of other risk factors. A key feature of the Cox model and other *survival analysis* techniques is that they accommodate censored data (when the time to event is known only to exceed a certain value). For example, if the outcome is time to stroke, the study will end with many subjects who have not had a stroke, so their time to stroke is known only to exceed the time to their last follow-up visit.

INFERRING POPULATION VALUES FROM A SAMPLE

The next step after describing the data is drawing inferences from a sample to the population from which the sample was drawn. Statistics mainly quantify random error, which arises by chance because even a sample randomly selected from a population may not be exactly like the population from which it was drawn. Samples that were not randomly selected from populations may be unrepresentative because of *bias,* and statistics cannot help with this type of systematic (nonrandom) error.

Inferences from Sample Means: Standard Deviation versus Standard Error

The simplest case of inference from a sample to a population involves estimating a population mean from a sample mean. Intuitively, the larger the sample size, *N*, the more likely it will be that the sample mean will be close to the population mean, that is, close to the mean that would be calculated if every member of the population were studied. The more variability there is in the population (and hence the sample), the less accurate the sample estimate of the population mean is likely to be. Thus, the precision with which a population mean can be estimated is related to both the size of the sample and the SD of the sample. To make inferences about a population mean from a sample mean, the *standard error of the mean* (SEM), which takes both of these factors into account, is as follows:

$$\text{SEM} = \frac{\text{SD}}{\sqrt{N}}$$

To understand the meaning of the SEM, imagine that instead of taking a single sample of *N* subjects from the population, many such samples were taken. The mean of each sample could be calculated, as could the mean of those sample means and the SD of these means. The SEM is the best estimate from a single sample of what that SD of sample means would be.

Confidence Intervals

The SEM expresses variability of sample means in the same way that the SD expresses variability of individual observations. Just as about 95% of *observations* in a population are expected to be within ±1.96 SD of the mean, 95% of *sample means* are expected to be within 1.96 SEM of the population mean, thereby providing the 95% confidence interval (CI), which is the range of values for the population mean consistent with what was observed from the sample.

CIs can similarly be calculated for other quantities estimated from samples, including proportions, ORs, RRs, regression coefficients, and hazard ratios. In each case, they provide a range of values for the parameter in the target population consistent with what was observed in the study sample.

Significance Testing and *P* Values

Many papers in the medical literature include *P* values, but the meaning of *P* values is widely misunderstood and mistaught. *P* values start with calculation of a *test statistic* from the sample that has a known distribution under certain assumptions, most commonly the *null hypothesis,* which states that there is no association between variables. *P* values provide the answer to the question, "If the null hypothesis were true, what would be the probability of obtaining, by chance alone, a value of the test statistic this large or larger (suggesting an association between groups of this strength or stronger)?" When the *P* value is small, there are two possible explanations. First, something with a small possibility of occurring actually happened; or second, the null hypothesis is false, and there is a true association. Values of *P* less than 0.05 are customarily described as "statistically significant."

There are a number of common pitfalls in interpreting *P* values. The first is that because *P* values less than .05 are customarily described as being "statistically significant," the description of results with *P* values less than .05 sometimes gets shortened to "significant" when in fact the results may not be clinically significant (i.e., important) at all. A lack of congruence between clinical and statistical significance most commonly arises when studies have a large sample size and the measurement is of a continuous or frequently occurring outcome.

A second pitfall is concluding that no association exists simply because the *P* value is greater than .05. However, it is possible that a real association exists, but that it simply was not found in the study. This problem is particularly likely if the sample size is small because small studies have low *power,* defined as the probability of obtaining statistically significant results if there really is a given magnitude of difference between groups in the population. One approach to interpreting a study with a nonsignificant *P* value is to examine the power that the study had to find a difference. A better approach is to look at the 95% CI. If the 95% CI excludes all clinically significant levels of the strength of an association, the study probably had an adequate sample size to find an association if there had been one. If not, a clinically significant effect may have been missed. In "negative" studies, the use of CIs is more helpful than power analyses because CIs incorporate information from the study's results.

Finally, a common misconception about *P* values is that they indicate the probability that the null hypothesis is true (e.g., that there is no association between variables). Thus, it is not uncommon to hear or read that a *P* value less than .05 implies at least a 95% probability that the observed association is not due to chance. This statement represents a fundamental misunderstanding of *P* values. Calculation of *P* values is *based on the assumption* that the null hypothesis is true. The probability that an association is real depends not just on the probability of its occurrence under the null hypothesis but also on the probability of another basis for the association (see later)—an assessment that depends on information from outside the study, sometimes called the *prior probability* of an association (of a certain magnitude) estimated before the study results were known and requiring a different approach to statistical inference. Similarly, CIs do not take into account previous information on the probable range of the parameter being estimated. Bayesian methods, which explicitly combine prior knowledge with new information, are beginning to enter the mainstream medical literature.[2]

Appropriate test statistics and methods for calculating *P* values depend on the type of variable, just as with descriptive statistics (see E-Table 9-1). For example, to test the hypothesis that the mean values of a continuous variable are equal in two groups, a *t* test would be used; to compare the mean values across multiple groups, analysis of variance would be used. Because there are many different ways for the null hypothesis to be false (i.e., many different ways that two variables might be associated) and many test statistics that could be calculated, there are many different ways of calculating a *P* value for

the association of the same two variables in a data set, and they may not all give the same answer.

Meta-analysis

Statistical techniques for inferring population values from a sample are not restricted to samples of individuals. *Meta-analysis* is a statistical method for drawing inferences from a sample of *studies* to derive a summary estimate and confidence interval for a parameter measured by the included studies, such as a risk ratio for a treatment effect.[3] Meta-analysis allows the formal combination of results while estimating and accommodating both the within-study and between-study variations. Meta-analysis is most often done when raw data from the studies are not available, as is typically the case when synthesizing information from multiple published results. For example, the previously cited estimate that a 1-g/day change in salt intake is associated with a 1-mm Hg change in blood pressure was obtained from a meta-analysis of randomized trials of low-salt diets in adults.

INFERRING CAUSALITY

In many cases, a goal of clinical research is not just to identify associations but also to determine whether they are *causal,* that is, whether the predictor causes the outcome. Thus, if people who take vitamin E live longer than those who do not, it is important to know whether it is *because* they took the vitamin or for some other reason.

Determination of causality is based on considering alternative explanations for an association between two variables and trying to exclude or confirm these alternative explanations. The alternatives to a causal relationship between predictor and outcome variables are *chance, bias, effect-cause,* and *confounding. P* values and CIs help assess the likelihood of *chance* as the basis for an association. *Bias* occurs when systematic errors in sampling or measurements can lead to distorted estimates of an association. For example, if those making measurements of the outcome variable are not blinded to values of the predictor variable, they may measure the outcome variable differently in subjects with different values of the predictor variable, thereby distorting the association between outcome and predictor.

Effect-cause is a particular problem in cross-sectional studies, in which (in contrast to longitudinal studies) all measurements are made at a single point in time, thereby precluding demonstration that the predictor variable preceded the outcome—an important part of demonstrating causality. Sometimes biology provides clear guidance about the direction of causality. For example, in a cross-sectional study relating levels of urinary cotinine (a measure of exposure to tobacco smoke) to decreases in pulmonary function, it is hard to imagine that poor pulmonary function caused people to be exposed to smoke. Conversely, sometimes inferring causality is more difficult: are people overweight because they exercise less, or do they exercise less because they are overweight (or both)?

Confounding

Confounding can occur when one or more extraneous variables are associated with both the predictor of interest and the outcome. For example, observational studies suggested that high doses of vitamin E might decrease the risk for heart disease. However, this association seems to have been largely due to confounding: people who took vitamin E were different in other ways from those who did not, including differences in factors causally related to coronary heart disease. If such factors are known and can be measured accurately, one way to reduce confounding is to *stratify* or *match* on these variables. The idea is to assemble groups of people who did and did not take vitamin E but who were similar in other ways. Multivariate analysis can accomplish the same goal—other measured variables are held constant statistically, and the effect of the variable of interest (in this case the use of vitamin E) can be examined. Multivariate analysis has the advantage that it can control simultaneously for more potentially confounding variables than can be considered with stratification or matching, but it has the disadvantage that a model must be created (see earlier), and this model may not fit the data well.

A new technique that is less dependent on model fit but still requires accurate measurements of confounding variables is the use of *propensity scores.* Propensity scores are used to assemble comparable groups in the same way as stratification or matching, but in this case the comparability is achieved on the basis of the *propensity* to be exposed to or be treated with the predictor variable of primary interest. Although propensity scores can adjust only for known confounders and are more subject to manipulation by investigators, systematic reviews suggest that they usually give answers that are generally similar to those of randomized trials addressing the same question.[4]

A major limitation of these methods of controlling for confounding is that the confounders must be known to the investigators and accurately measured. In the case of vitamin E, apparent favorable effects persisted after controlling for known confounding variables. It is for this reason that randomized trials provide the strongest evidence for causality. If the predictor variable of interest can be randomly assigned, confounding variables, both known and unknown, should be approximately equally distributed between the subjects who are and are not exposed to the predictor variable, and it is reasonable to infer that any significant differences in outcome that remain in these now comparable groups would be due to differences in the predictor variable of interest. In the case of vitamin E, a recent meta-analysis of randomized trials found no benefit and in fact suggested harm from high doses.

OTHER COMMON STATISTICAL PITFALLS

Missing Data

Research on human subjects is challenging. People drop out of studies, refuse to answer questions, miss study visits, and die of diseases that are not being studied directly in the protocol. Consequently, missing or incomplete data are a fact of medical research. When the particular data that are missing are unrelated to the outcome being studied (which might be true, for example, if the files storing the data got partially corrupted), analyses using only the data present (sometimes called a complete case analysis) are unlikely to be misleading. Unfortunately, such is rarely the case. Subjects refusing to divulge family income probably have atypical values, patients not coming for scheduled visits in a study of depression may be more or less depressed, and patients in an osteoporosis study who die of heart disease probably differ in many ways from those who do not.

Whenever a sizable fraction of the data is missing (certainly if it is above 10 or 15%), there is the danger of substantial bias from an analysis that uses only the complete data. This is the gap noted earlier between the intended and actual samples. Any study with substantial missing data should be clear about how many missing data there were and what was done to assess or alleviate the impact; otherwise, the critical consumer of such information should be suspicious. Multiple imputation is a technique of using observations with nonmissing data to estimate missing values; it can produce less biased estimates than simply excluding the observations with missing data.[5] In a randomized trial, the general rule is that the primary analysis should include all subjects who were randomized, regardless of whether they followed the study protocol, in an *intention-to-treat* analysis.

Clustered or Hierarchical Data

Data are often collected in a clustered (also called hierarchical) manner; for example, NHANES used a cluster sample survey, and a study of patient outcomes might be conducted at five hospitals, each with multiple admission teams. The cluster sample or the clustering of patients within teams within hospitals leads to correlated data. Said another way, and other things being equal, data collected on the same patient, by the same admission team, or in the same cluster are likely to be more similar than data from different patients, teams, or clusters. Failure to use statistical methods that accommodate correlated data can seriously misstate standard errors, widths of CIs, and *P* values, most often leading to overly optimistic estimates, that is, standard errors and *P* values that are incorrectly too small and CIs that are incorrectly too narrow. Statistical methods for dealing with correlated data include *generalized estimating equations* and the use of *robust standard errors* and *frailty models* (for time-to-event data). Studies with obvious hierarchical structure that fail to use such methods may be in serious error.

Multiple Hypothesis Testing

The "multiple hypothesis testing" or "multiple comparisons" issue refers to the idea that if multiple statistical tests are conducted, each at a significance level of .05, the chance that at least one of them will achieve a *P* value of less than .05 is considerably larger than .05, even when all the null hypotheses are true. For example, when comparing the mean value of a continuous variable across many different groups, analysis of variance is a time-tested method of performing an overall test of equality and avoiding making a large number of pairwise comparisons.

Because most medical studies collect data on a large number of predictor variables, performing a test on the association of each one with the outcome may generate false-positive results. The risk for falsely positive results is especially high with genomic studies, in which a researcher may test a million single-nucleotide polymorphisms for association with a disease.

A typical method for dealing with the problem of multiple testing is the *Bonferroni correction,* which specifies that the *P* value at which the null hypothesis will be rejected (e.g., .05) should be *divided by the number of hypothesis tests performed*. Although simple to use, a problem with this approach is that it is overly conservative. Studies with many listed or apparent outcomes or predictors (or both) are subject to inflation of the error rate to well above the nominal .05. Automated stepwise regression methods for choosing predictors in regression models typically *do not* alleviate and may exacerbate this problem. If no adjustment or method for dealing with multiple comparisons is used, the high probability of false-positive results should be kept in mind.

REVIEW QUESTIONS

1. A study of 105 vegan Buddhist nuns randomly sampled from monasteries around Ho Chi Minh City found that the average femoral neck bone mineral density was 0.62 g/cm^2, with a standard deviation of 0.11 g/cm^2 (Ho-Pham LT, Nguyen PL, Le TT, et al. Veganism, bone mineral density, and body composition: a study in Buddhist nuns. *Osteoporos Int.* 2009;20:2087-2093). Which of the following statements about this result is correct?

A. The 95% confidence interval for the mean bone mineral density in these women is about 0.4 to 0.84 g/cm^2.
B. If bone mineral density is normally distributed, we would expect about 10% of the women in the sample to have bone mineral density outside of the interval: 0.4 to 0.84 g/cm^2.
C. The 95% confidence interval for the mean bone mineral density in these women is about 0.60 to 0.64 g/cm^2.
D. Because the women were sampled randomly, there is a 95% chance that a randomly selected woman from the *population* would have a bone mineral density between 0.60 and 0.64 g/cm^2.
E. Because the women were sampled randomly, there is a 95% chance that a randomly selected woman from the *sample* would have a bone mineral density between 0.60 and 0.64 g/cm^2.

Answer: C We would expect about 95% of *observations* to be within 2 standard deviations of the sample mean, leaving 5% out, so choice B is incorrect. The 95% confidence interval for a sample mean is about mean ± 2 standard errors of the mean (SEM), where the $\text{SEM} = \frac{\text{SD}}{\sqrt{N}}$. In this case, the SD is 0.11 g/cm^2, and the N is about 100, so the SEM will be about 0.11/10 = 0.01 g/cm^2, and the 95% CI will be about 0.60 to 0.64 g/cm^2, as indicated in choice C. Choices D and E are incorrect because the range given is too narrow: it is ± 2 SEM when it should be ± 2 SD.

2. A study of data collected through the Get with the Guidelines-Stroke Program examined the time from onset of stroke symptoms to treatment with tissue-type plasminogen activator (tPA) among 58,353 patients with acute ischemic stroke treated within 4.5 hours of the onset of symptoms (Saver JL, Fonarow GC, Smith EE, et al. Time to treatment with intravenous tissue plasminogen activator and outcome from acute ischemic stroke. *JAMA.* 2013;309:2480-2488). The authors reported that "faster onset-to treatment time, in 15-minute increments, was associated with … increased achievement of independent ambulation at discharge (OR, 1.04; 95% CI 1.03-1.05; P < 0.001) … ." Which of the following is a correct interpretation of these findings?

A. In this study, the effect of a 15-minute reduction in onset-to treatment time was associated with a 4 % (relative) increase in the odds of independent ambulation at discharge.
B. Because the odds ratio is very close to 1.0, the results are not statistically significant.
C. Because the odds ratio is very close to 1.0, the results, although highly statistically significant, are not clinically significant.
D. The 4% increase in odds of independent ambulation translates into a number-needed-to treat (NNT) of 25.
E. None of the above is correct.

Answer: A Choice A exactly expresses the meaning of the odds ratio for this study. Choices B and C are incorrect because the proximity of the odds ratio to 1 is in this case based partly on the choice of the authors to express it per 15 minutes onset-to-treatment time. This illustrates the importance of knowing the units of the predictor variable when it is not dichotomous. If the authors had expressed the difference per hour instead of per 15 minutes, the odds ratios would have been taken to the fourth power, that is, the odds ratio for independent ambulation at discharge would have been about $1.04^4 = 1.17$. Choice D is incorrect because estimation of the NNT requires knowing the absolute risk reduction, which was not provided in this case.

3. Assume a study of both smoking and nonsmoking mothers reports that the effect of smoking on birthweight is about a 32-g decrease in birthweight per cigarette smoked per day during pregnancy (similar to what is reported by Juarez SP, Merlo J. Revisiting the effect of maternal smoking during pregnancy on offspring birthweight: a quasi-experimental sibling analysis in Sweden. *PLoS One.* 2013;8:e61734.). Which of the following statements about this finding is NOT correct?

A. The result is based on a *model*, in which the predicted birthweight is linearly related to the number of cigarettes smoked per day.
B. This model predicts that the difference in birthweight between a baby whose mother did not smoke and one who smoked 5 cigarettes per day is the same as the difference between babies of mothers who smoked 20 and 25 cigarettes per day.
C. The model predicts the same effect of smoking on birthweight, regardless of the mother's age and prepregnancy weight.
D. This model predicts that cutting cigarette smoking in half will lead to a 64-g expected weight increase in the baby.
E. The model could include additional terms that would reflect the effect of mother's age and prepregnancy weight.

Answer: D Choices A, B and C accurately describe characteristics of a linear model for the effect of smoking on birthweight. Choice D is not consistent with a linear model. Choice E reflects that the effects of other variables can be taken into account, while still maintaining a linear model for the effect of cigarettes smoked on birthweight.

4. A case-control study of the relationship of breast cancer and the use of COX-2 inhibitors found that the odds ratio and confidence interval relating cancer to use of baby aspirin were OR = 0.77 and 95% CI (0.42-1.41) (Harris RE, Beebe-Donk J, Alshafie GA. Reduction in the risk of human breast cancer by selective cyclooxygenase-2 [COX-2] inhibitors. *BMC Cancer.* 2006;6:27). The authors then stated, "Neither acetaminophen nor baby aspirin had any effect on the relative risk of breast cancer." This is incorrect because of which of the following?

A. The confidence interval crosses 1.
B. The authors do not give the *P* value.
C. The confidence interval has a lower limit of 0.42.
D. Odds ratios are inappropriate for this study.
E. The authors should have used a higher level of confidence.

Answer: C C is correct because the confidence interval allows for a 58% reduction (from [1 to 0.42]*100%) in the chance of breast cancer associated with the use of baby aspirin, a potentially important effect. Choice A is incorrect because it merely indicates a lack of a statistically significant result and does not bear on the size of the effect. Choice B is incorrect because CIs are more useful for ruling out important effects. Odds ratios are especially useful in case-control studies, so D is incorrect. And E is incorrect because a higher level of confidence would make the CI even wider.

5. In a randomized trial of an intervention to reduce hypertension, researchers selected subjects from a single antihypertensive patient club in Shanghai (Xue F, Yao W, Lewin RJ. A randomised trial of a 5 week, manual based, self-management programme for hypertension delivered in a cardiac patient club in Shanghai. *BMC Cardiovasc Disord.* 2008;8:10). About one third of those approached agreed to be randomized. The results of this study can be safely generalized to which of the following?

A. All hypertensives
B. All hypertensives in China
C. All hypertensives in Shanghai
D. All hypertensives belonging to the single club in Shanghai
E. None of the above.

Answer: E Because two thirds of the participants refused to participate, the extrapolation of the effect of the intervention might not even apply to the particular club in which the study was conducted, much less a broader population.

10 USING DATA FOR CLINICAL DECISIONS

THOMAS H. LEE

TABLE 10-1 KEY DEFINITIONS*

Probability	A number between 0 and 1 that expresses an estimate of the likelihood of an event
Odds	The ratio of [the probability of an event] to [the probability of the event's not occurring]
TEST PERFORMANCE CHARACTERISTICS	
Sensitivity	Percentage of patients with disease who have an abnormal test result
Specificity	Percentage of patients without disease who have a normal test result
Positive predictive value	Percentage of patients with an abnormal test result who have disease
Negative predictive value	Percentage of patients with a normal test result who do not have disease
BAYESIAN ANALYSIS	
Pretest (or prior) probability	The probability of a disease before the information is acquired
Post-test (or posterior) probability	The probability of a disease after new information is acquired
Pretest (or prior) odds	(Pretest probability of disease)/(1 – pretest probability of disease)
Likelihood ratio	(Probability of result in diseased persons)/(Probability of result in nondiseased persons)

**Disease* can mean a condition, such as coronary artery disease, or an outcome, such as postoperative cardiac complications.

Key functions in the professional lives of all physicians are the collection and analysis of clinical data. Decisions must be made on the basis of these data, including which therapeutic strategy is most appropriate for the patient and whether further information should be gathered before the best strategy can be chosen. This decision-making process is a blend of science and art in which the physician must synthesize a variety of concerns, including the patient's most likely outcome with various management strategies, the patient's worst possible outcome, and the patient's preferences among these strategies.

Only rarely does the physician enjoy true certainty regarding any of these issues, so a natural inclination for physicians is to seek as much information as possible before making a decision. This approach ignores the dangers inherent in the collection of information. Some of these dangers are immediate, such as the risk of cerebrovascular accident associated with coronary angiography. Some dangers are delayed, such as the risk of a malignant neoplasm due to radiation exposure from diagnostic tests. And some dangers are subtle, such as the risk of unnecessary anguish for patients due to delays, uncertainty, and confusion.

An additional concern is the cost of information gathering, including the direct costs of the tests themselves and the indirect costs that flow from decisions made on the basis of the test results. Substantial data demonstrate marked variation in use of tests among physicians located in different regions and even within the same group practice. Standards of medical professionalism endorse the need for physicians to exert their influence to minimize inefficiency, but this challenge grows increasingly complex as medical progress leads to proliferation of alternative testing strategies.

For the physician, there are three key questions in this sequence: Should I order a test to improve my assessment of diagnosis or prognosis? Which test is best? Which therapeutic strategy is most appropriate for this patient?

SHOULD I ORDER A TEST?

The decision of whether to order a test depends on the physician's and the patient's willingness to pursue a management strategy with the current degree of uncertainty.[1] This decision is influenced by several factors, including the patient's attitudes toward diagnostic and therapeutic interventions (e.g., a patient with claustrophobia might prefer an ultrasound to magnetic resonance imaging) and the information provided by the test itself. The personal tolerance of the patient and physician for uncertainty also frequently influences test-ordering approaches. A decision to watch and wait rather than to obtain a specific test also should be considered an information-gathering alternative because the information obtained while a patient is being observed often reduces uncertainty about the diagnosis and outcome. In other words, the "test of time" should be recognized as one of the most useful tests available when this tactic does not seem inappropriately risky.

Most tests do not provide a definitive answer about diagnosis or prognosis but instead reduce uncertainty. Accordingly, the impact of information from tests often is expressed as *probabilities* (Table 10-1). A probability of 1.0 implies that an event is certain to occur, whereas a probability of 0 implies that the event is impossible. When all the possible events for a patient are assigned probabilities, these estimates should sum to 1.0.

It is often useful to use *odds* to quantify uncertainty instead of probability. Odds of 1 : 2 suggest that the likelihood of an event is only half the likelihood that the event will not occur, or a probability of 0.33. The relationship between odds and probability is expressed in the following formula:

$$\text{Odds} = P/(1-P)$$

where P is the probability of an event.

Performance Characteristics

Sensitivity and *specificity* are key terms for the description of test performance. These parameters describe the test and are in theory true regardless of the population of patients to which the test is applied. Research studies that describe test performance often are based, however, on highly selected populations of patients; test performance may deteriorate when tests are applied in clinical practice. The result of a test for coronary artery disease, such as an electron beam computed tomography scan, rarely may be abnormal if it is evaluated in a low-risk population, such as high-school students. False-positive abnormal results secondary to coronary calcification in the absence of obstructive coronary disease are common when the test is performed in middle-aged and elderly people. Another increasingly appreciated factor that can distort the performance of screening tests is the phenomenon of "overdiagnosis," in which the "disease" that is detected would not have led to clinical harm if it had not been found.[2]

Although researchers are interested in the performance of tests, the true focus of medical decision making is the patient. Physicians are more interested in the implications of a test result on the probability that a patient has a specific disease or outcome, that is, the predictive values of abnormal or normal test results. These predictive values are extremely sensitive to the population from which they are derived (Table 10-2; see also Table 10-1). An abnormal lung scan result in an asymptomatic patient has a much lower positive predictive value than that same test result in a patient with dyspnea and diminished oxygen saturation. Bayes theorem (see later) provides a

TABLE 10-2 EXAMPLE OF ODDS RATIO FORM OF BAYES THEOREM

Question: What is the probability of coronary disease for a patient with a 50% pretest probability of coronary disease who undergoes an exercise test if that patient develops (a) no ST segment changes, (b) 1 mm of ST segment depression, or (c) 2 mm of ST segment depression?

Step 1. Calculate the pretest odds of disease:

$$P/(1-P) = 0.5/(1-0.5)$$
$$= 0.5/0.5$$
$$= 1$$

Step 2. Calculate the likelihood ratios for the various test results, using the formula LR = sensitivity/(1 − specificity). (Data from pooled literature.)

TEST RESULT	SENSITIVITY	SPECIFICITY	LIKELIHOOD RATIO
No ST segment changes	0.34	0.15	0.4
1-mm ST segment depression	0.66	0.85	4.4
2-mm ST segment depression	0.33	0.97	11

Step 3. Calculate the post-test odds of disease and convert those odds to post-test probabilities.

TEST RESULT	PRETEST ODDS	LIKELIHOOD RATIO	POST-TEST ODDS	POST-TEST PROBABILITY
No ST segment changes	1	0.4	0.4	0.29
1-mm ST segment depression	1	4.4	4.4	0.81
2-mm ST segment depression	1	11	11	0.92

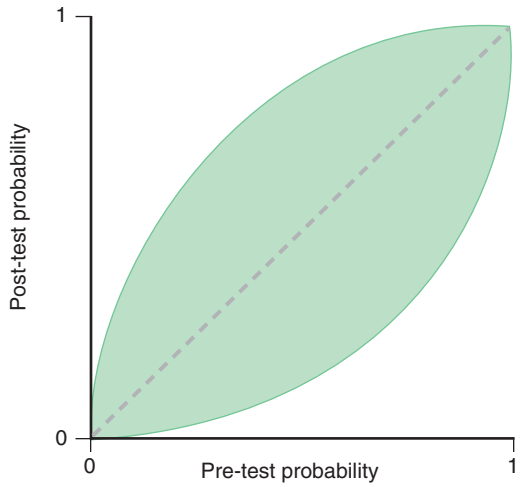

FIGURE 10-1. Impact of various test results on the patient's probability of disease. The *x*-axis depicts a patient's probability of disease before a test. If the test is of no value, the post-test probability (*dotted line*) is no different from the pretest probability. An abnormal test result raises the post-test probability of disease, as depicted by the concave downward arc, whereas a normal test result lowers the probability.

framework for analyzing the interaction between test results and a patient's pretest probability of a disease.

As useful as the performance characteristics may be, they are limited by the fact that few tests truly provide dichotomous (i.e., positive or negative) results. Tests such as exercise tests have several parameters (e.g., ST segment deviation, exercise duration, hemodynamic response) that provide insight into the patient's condition, and the normal range for many blood tests (e.g., a serum troponin level) varies markedly according one's willingness to "miss" patients with disease. Tests that require human interpretation (e.g., radiologic studies) are particularly subject to variability in the reported results.

Bayes Theorem

The impact of a test result on a patient's probability of disease was first quantified by Bayes, an 18th century English clergyman who developed a formula that describes the probability of disease in the presence of an abnormal test result. The classic presentation of Bayes theorem is complex and difficult to use. A more simple form of this theorem is known as the *odds ratio* form, which describes the impact of a test result on the pretest odds (see Table 10-1) of a diagnosis or outcome for a specific patient.

To calculate the post-test odds of disease, the pretest odds are multiplied by the *likelihood ratio* (LR) for a specific test result. The mathematical presentation of this form of Bayes theorem is as follows:

$$\text{Post-test odds} = (\text{Pretest odds}) \times (\text{LR})$$

The LR is the probability of a particular test result in patients with the disease divided by the probability of that same test result in patients without disease. In other words, the LR is the test result's sensitivity divided by the false-positive rate. A test of no value (e.g., flipping a coin and calling "heads" an abnormal result) would have an LR of 1.0 because half of patients with disease would have abnormal test results, as would half of patients without disease. This test would have no impact on a patient's odds of disease. The further an LR is above 1.0, the more that test result raises a patient's probability of disease. For LRs less than 1.0, the closer the LR is to 0, the more it lowers a patient's probability of disease.

When it is displayed graphically (Fig. 10-1), a test of no value (*dotted line*) does not change the pretest probability, whereas an abnormal or normal result from a useful test moves the probability up or down. For a patient with a high pretest probability of disease, an abnormal test result changes the patient's probability only slightly, but a normal test result leads to a marked reduction in the probability of disease. Similarly, for a patient with a low pretest probability of disease, a normal test result has little impact, but an abnormal test result markedly raises the probability of disease.

Consider how various exercise test results influence a patient's probability of coronary disease (see Table 10-2). For a patient whose clinical history, physical examination, and electrocardiographic findings suggest a 50% probability of disease, the pretest odds of disease are 1.0. LRs for various test results are developed by pooling data from published literature. The sensitivity of an exercise test with any amount of ST segment changes is the rate of such test results in patients with coronary disease, and the specificity is the percentage of patients without coronary disease who do *not* have this test result. The LR for no ST change is less than 1, whereas the LRs for patients with ST changes are greater than 1 (see Table 10-2). Therefore, when the LRs for various test results are multiplied by the pretest odds to calculate post-test odds, the odds decrease for patients without ST segment changes but increase for patients with 1 or 2 mm of ST segment change. Post-test odds can be converted to post-test probabilities according to the following formula:

$$\text{Probability} = \text{Odds}/(1+\text{odds})$$

The calculations quantify how the absence of ST segment changes reduces a patient's probability of disease, whereas ST segment depression raises the probability of disease.

This form of Bayes theorem is useful for showing how the post-test probability of disease is influenced by the patient's pretest probability of disease. If a patient's clinical data suggest a *probability* of coronary disease of only 0.1, the *pretest odds* of disease would be only 0.11. For such a low-risk patient, an exercise test with no ST segment changes would lead to post-test probability of coronary disease of 4%, whereas 1-mm or 2-mm ST segment changes would lead to a post-test probability of disease of 33% or 55%, respectively.

Even if clinicians rarely perform the calculations that are described in Bayes theorem, there are important lessons from this theorem that are relevant to principles of test ordering (Table 10-3). The most crucial of these lessons is that the interpretation of test results must incorporate information about the patient. An abnormal test result in a low-risk patient may not be a true indicator of disease. Similarly, a normal test result in a high-risk patient should not be taken as evidence that disease is not present.

Figure 10-2 provides an example of the post-test probabilities for positive and negative results for a test with a sensitivity of 85% and a specificity of 90% (e.g., radionuclide scintigraphy for diagnosis of coronary artery disease). In a high-risk population with a 90% prevalence of disease, the positive predictive value of an abnormal result is 0.99 compared with 0.31 for the same test result obtained in a low-risk population with a 5% prevalence of disease. Similarly, the negative predictive value of a normal test result is greater in the low-risk population than in the high-risk population.

TABLE 10-3 PRINCIPLES OF TEST ORDERING AND INTERPRETATION

The interpretation of test results depends on what is already known about the patient.
No test is perfect; clinicians should be familiar with its diagnostic performance (see Table 10-1) and never believe that a test "forces" them to pursue a specific management strategy.
Tests should be ordered if they may provide *additional* information beyond that already available.
Tests should be ordered if there is a reasonable chance that the data will influence the patient's care.
Two tests that provide similar information should not be ordered.
In choosing between two tests that provide similar data, use the test that has lower costs or causes less discomfort and inconvenience to the patient.
Clinicians should seek all of the information provided by a test, not just an abnormal or normal result.
The cost-effectiveness of strategies using noninvasive tests should be considered in a manner similar to that of therapeutic strategies.

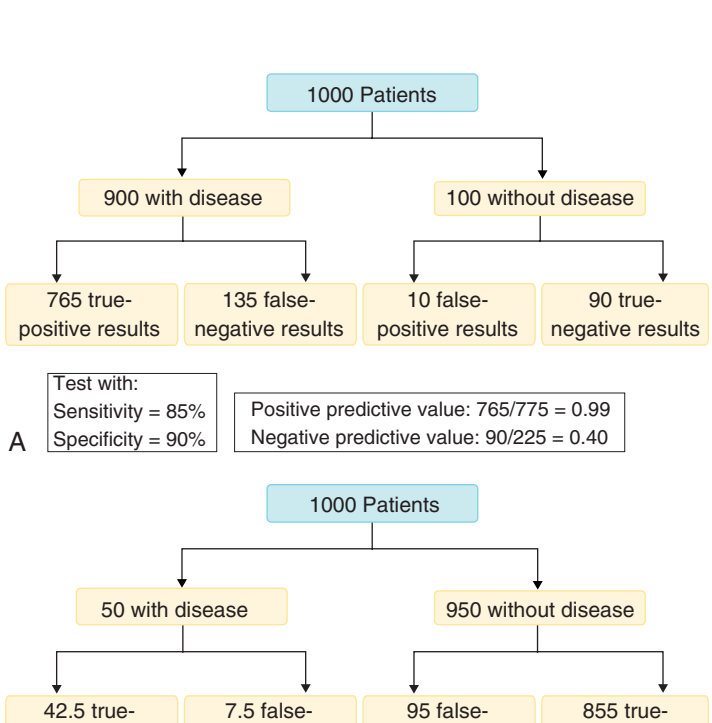

FIGURE 10-2. Interpretation of test results in high-risk and low-risk patients. A, High-risk population (90% prevalence of disease). B, Low-risk population (5% prevalence of disease).

Multiple Testing

Clinicians frequently obtain more than one test aimed at addressing the same issue and at times are confronted with conflicting results. If these tests are truly independent (i.e., the tests do not have the same basis in pathophysiology), it may be appropriate to use the post-test probability obtained through performance of one test as the pretest probability for the analysis of the impact of the second test result.

If the tests are not independent, this strategy for interpretation of serial test results can be misleading. Suppose a patient with chronic obstructive pulmonary disease and a history vaguely suggestive of pulmonary embolism is found to have an abnormal lung ventilation-perfusion scan. Obtaining that same test result over and over would not raise that patient's probability of pulmonary embolism further and further. In this extreme case, the tests are identical; serial testing adds no information. More commonly, clinicians are faced with results from tests with related but not identical bases in pathophysiology, such as ventilation-perfusion scintigraphy and pulmonary angiography.

Regardless of whether tests are independent, the performance of multiple tests increases the likelihood that an abnormal test result will be obtained in a patient without disease. If a chemistry battery includes 20 tests and the normal range for each test has been developed to include 95% of healthy individuals, the chance that a healthy patient will have a normal result for any specific test is 0.95. However, the probability that all 20 tests will be normal is $(0.95)^{20}$, or 0.36. Most healthy people can be expected to have at least one abnormal result. Unless screening test profiles are used thoughtfully, false-positive results can subject patients to unnecessary tests and procedures.

Threshold Approach to Decision Making

Even if a test provides information, that information may not change management for an individual patient. Lumbar spine radiographs of a patient who is not willing to undergo surgery may reveal the severity of disease but expose the patient to needless radiation. Similarly, a test that merely confirms a diagnosis that already is recognized is a waste of resources (see Table 10-3).

Before ordering a test, clinicians should consider whether that test result could change the choice of management strategies. This approach is called the *threshold approach to medical decision making*, and it requires the physician to be able to estimate the threshold probability at which one strategy will be chosen over another. The management of a clinically stable patient with a high probability of coronary disease might not be changed by any of the post-test probabilities shown in Table 10-2. If that patient had no ST segment changes, the post-test probability of 0.29 still would be too high for a clinician to consider that patient free of disease. An abnormal test result that strengthened the diagnosis of coronary disease might not change management unless it suggested a greater severity of disease that might warrant another management strategy.

Testing for Peace of Mind

Physicians frequently order tests even when there is little chance that the outcomes will provide qualitatively new insights into a patient's diagnosis or prognosis or alter a patient's management. In such cases, the cited goal for testing may be to improve a patient's peace of mind. Although a decrease in uncertainty can improve quality of life for many patients, individuals with hypochondriasis and somatization disorders rarely obtain comfort from normal test results; instead, their complaints shift to a new organ system, and their demands focus on other tests. For such patients, management strategies using frequent visits and cognitive tactics are recommended.

WHICH TEST IS BEST?

If the clinician decides that more information is needed to reduce uncertainty, and if it appears possible that tests might lead to a change in management strategies, the question arises as to which test is most appropriate. Note that just because guideline development committees have concluded that a specific test is "appropriate" in a given clinical context, it does not mean that this test is the *most* appropriate option. Several factors influence the choice among diagnostic strategies, including the patient's preferences, the costs and risks associated with the tests, and the diagnostic performance of alternative tests.

Diagnostic performance of a test often is summarized in terms of sensitivity and specificity,[3] but as shown in the example in Table 10-2, these parameters depend on which threshold (e.g., 1 mm vs. 2 mm of ST segment change) is used. A low threshold for calling a test result abnormal might lead to excellent sensitivity for detecting disease but at the expense of a high false-positive rate. Conversely, a threshold that led to few false-positive results might cause a clinician to miss many cases of true disease.

The receiver operating characteristic (ROC) curve is a graphic form of describing this tradeoff and providing a method for comparing test performance (Fig. 10-3). Each point on the ROC curve describes the sensitivity and the false-positive rate for a different threshold for abnormality for a test. A test of no value would lead to an ROC curve with the course of the dotted line, whereas a misleading test would be described by a curve that was concave upward (not shown).

The more accurate the test, the closer its ROC curve comes to the upper left corner of the graph, which would indicate a test threshold that has excellent sensitivity and a low false-positive rate. The closer an ROC curve comes to the upper left corner, the greater the area under the curve. The area under ROC curves can be used to compare the information provided by two tests.

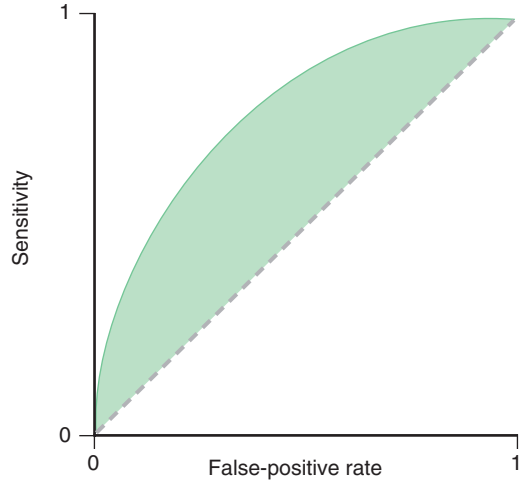

FIGURE 10-3. Receiver operating characteristic curve. The points on the curve reflect the sensitivity and false-positive (1 – specificity) rates of a test at various thresholds. As the threshold is changed to yield greater sensitivity for detecting the outcome of interest, the false-positive rate rises. The better the test, the closer the curve comes to the upper left corner. A test of no value (e.g., flipping a coin) would lead to a curve with the course of the dotted line. The area under the curve is used often to compare alternative testing strategies.

Even if one test is superior to another as shown by a greater area under its ROC curve, the question still remains as to what value of that test should be considered abnormal. The choice of threshold depends on the purpose of testing and on the consequences of a false-positive or false-negative diagnosis. If the goal is to screen the population for a disease that is potentially fatal and potentially curable, a threshold with excellent sensitivity is appropriate even if it leads to frequent false-positive results. In contrast, if a test is used to confirm a diagnosis that is likely to be treated with a high-risk invasive procedure, a threshold with high specificity is preferred. Only 1 mm of ST segment depression might be the appropriate threshold when exercise electrocardiography is used to evaluate the possibility of coronary disease in a patient with chest pain. If the question is whether to perform coronary angiography in a patient with stable angina in search of severe coronary disease that might benefit from revascularization, a threshold of 2 mm or more would be more appropriate.

CHOOSING A STRATEGY

Physicians and patients ultimately must use clinical information to make decisions. These choices usually are made after consideration of a variety of factors, including information from the clinical evaluation, patients' preferences, and expected outcomes with various management strategies. Insight into the impact of these considerations can be improved through the performance of decision analysis (Table 10-4).

The first step in a decision analysis is to define the problem clearly; this step often requires writing out a statement of the issue so that it can be scrutinized for any ambiguity. After the problem is defined, the next step is to define the alternative strategies.

Consider the question of which test is most appropriate to screen patients for breast cancer: mammography with or without breast magnetic resonance imaging—a technology that is highly sensitive for detecting breast cancer but is more costly and less specific. The expected outcomes for these strategies depend on each test's sensitivity and specificity for detecting breast cancer, which is influenced in turn by other factors, such as the frequency with which the test is performed. Patients' outcomes also are influenced by their underlying risk for breast cancer and the likelihood that earlier detection of tumors reduces the risk for death.

Each of these variables must be known or estimated for calculations to be made of each strategy's predicted life expectancy and direct medical costs. These outcomes differ for patients according to age, medical history, family history, and presence or absence of genetic markers such as *BRCA* mutations. Optimal strategies for an elderly patient with a short life expectancy and low clinical risk of cancer are unlikely to be the same as those for a younger patient with inherited mutations of the *BRCA1* or *BRCA2* gene, indicating a cumulative lifetime risk of breast cancer of 50 to 85% (Chapter 198).

TABLE 10-4 STEPS IN PERFORMANCE OF DECISION ANALYSIS

Frame the question.
Create the decision tree.
Identify the alternative strategies.
List the possible outcomes for each of the alternative strategies.
Describe the sequence of events as a series of decision nodes and chance nodes.
Choose a time horizon for the analysis.
Determine the probability for each chance outcome.
Assign a value to each outcome.
Calculate the expected utility for each strategy.
Perform sensitivity analysis.

The credibility of the decision analysis depends on the credibility of these estimates. Published reports often do not provide information on the outcomes of interest for specific subsets of patients, or there may not have been sufficient statistical power within subsets of patients for the findings to be statistically significant. Randomized trial data are relevant to the populations included in the trial; the extension of the findings to other genders, races, and age groups requires assumptions by individuals performing the analysis. For many issues, expert opinion must be used to derive a reasonable estimate of the outcome.

For many diseases, the potential outcomes are more complex than perfect health or death. With chronic diseases, patients may live many years in a condition somewhere between these two, and the goal of medical interventions may be to improve quality of life rather than to extend survival. The value of life in imperfect health must be reflected in decision analyses. These values by convention are expressed on a scale of 0 to 100, where 0 indicates the worst outcome and 100 indicates the best outcome.

Life-expectancy and quality-of-life estimates are combined in many decision analyses to calculate *quality-adjusted life years.* A strategy that leads to a 10-year life expectancy with such severe disability that utility of the state of health is only half that of perfect health would have a quality-adjusted life expectancy of 5 years. With such adjustments to life-expectancy data, the impact of interventions that improve quality of life but do not extend life can be compared with interventions that extend life but do not improve its quality or perhaps even worsen it.[4]

After the value and the probability of the various outcomes have been estimated, the expected utility of each strategy can be calculated. In comparing the different strategies available at a decision node, the analysis generally selects the option with the highest expected utility. At chance nodes, the expected utility is the weighted average of the utility of the various possible branches.

After the analysis has been performed with the baseline assumptions, *sensitivity analyses* should be performed in which these assumptions are varied over a reasonable range. These analyses can reveal which assumptions have the most influence over the conclusions and identify threshold probabilities at which the conclusions would change. For example, the threshold at which breast magnetic resonance imaging should be added to mammography is likely to be influenced by the cost of the magnetic resonance imaging and the accuracy of the radiologists who interpret the images.

Cost-Benefit and Cost-Effectiveness Analyses

For clinicians and health care policymakers, the choices that must be addressed go beyond the choices within any single decision analysis. Because resources available for health care are limited, policymakers may have to choose among many competing options for "investments" in health. Although such decisions frequently are made on the basis of political considerations, cost-benefit and cost-effectiveness analyses can be informative in making the choices.

The methodology of these techniques is similar to that of decision analysis except that costs for the various possible outcomes and strategies also are calculated. *Discounting* is used to adjust the value of future benefits and costs because resources saved or spent currently are worth more than resources saved or expended in the future. In *cost-benefit* analyses, all benefits are expressed in terms of economic impact. Extensions in life expectancy are translated into dollars by estimating societal worth or economic productivity.

Because of the ethical discomfort associated with expressing health benefits in financial terms, *cost-effectiveness* analyses are used more commonly

TABLE 10-5 ESTIMATED COST-EFFECTIVENESS OF SELECTED HEALTH INTERVENTIONS

INTERVENTION	COST PER QUALITY-ADJUSTED LIFE YEAR (QALY) (2010 DOLLARS)
Treating rheumatoid arthritis with drugs that slow disease progression	Saves money and improves health
Using warfarin for 70-year-olds with atrial fibrillation	$3,000 per QALY
Daily dialysis for 60-year old critically ill men with kidney injury	$6,000 per QALY
Using an implantable cardioverter-defibrillator to prevent sudden cardiac death in high-risk patients	$38,000 per QALY
Treating spinal stenosis and leg pain with spine surgery	$90,000 per QALY
Screening 60-year-old heavy smokers with annual CT scans	$140,000 per QALY
Annual HIV screening for people with a low to moderate risk	Increases costs and makes health worse

Modified from the CEA Registry.[6]

than cost-benefit analyses. In these analyses, the ratio of costs to health benefits is calculated; one frequently used method for evaluating a strategy is calculation of cost per quality-adjusted life year.[5] These estimates can be used to identify strategies that are both cost-saving and health-improving, to compare strategies by which the health care system can "purchase" additional quality-adjusted life years, and even to caution about strategies that increase costs while worsening health (Table 10-5).[6]

Cost-effectiveness analyses can provide important insights into the relative attractiveness of different management strategies and can help guide policymakers in decisions about which technologies to make available on a routine basis. No medical intervention can have an attractive cost-effectiveness if its effectiveness has not been proved. The cost-effectiveness of an intervention depends heavily on the population of patients in which it is applied. An inexpensive intervention would have a poor cost-effectiveness ratio if it were used in a low-risk population unlikely to benefit from it. In contrast, an expensive technology can have an attractive cost-effectiveness ratio if it is used in patients with a high probability of benefiting from it. Table 10-5 shows cost-effectiveness estimates from published literature for some selected medical interventions. Such estimates should be used only with understanding of the population for which they are relevant.

REVIEW QUESTIONS

1. A 53-year-old man presents to his primary care physician with a chief complaint of chest pain for the past 2 weeks. The pain is described as intermittent, usually exertional, midline, and aching in nature. His electrocardiogram is completely normal. Which one of the following is the most appropriate next step?

A. Watch and wait
B. Exercise electrocardiography
C. B-type natriuretic peptide
D. Exercise nuclear scintigraphy
E. Coronary angiography

Answer: B The immediate question is whether this patient's symptoms represent new ischemic heart disease. His clinical presentation suggests a moderate probability of coronary artery disease, so watch-and-wait is probably too risky a strategy. At the same time, he does not appear to have unstable ischemic disease, so there is no need to proceed immediately to coronary angiography in preparation for coronary revascularization. Measurement of B-type natriuretic peptide would not alter management. Of the two noninvasive tests for ischemic heart disease, exercise electrocardiography is the least expensive, is the most convenient, and carries no radiation exposure. Guidelines would thus suggest that answer B is the most appropriate next step.

2. A patient undergoes an exercise test and has 2 mm of ST-segment depression on electrocardiogram. In which one of these patients would this finding be most likely to change management?

A. A healthy 19-year-old volunteer in a research study
B. A 62-year-old woman who is completely asymptomatic
C. A 62-year-old woman with frequent nonexertional aching chest pain
D. A 62-year-old woman with recent myocardial infarction and chest pain at rest
E. A 62-year-old woman who is completely symptom free 4 months after coronary artery bypass graft surgery

Answer: C Patients A and B have a sufficiently low probability of coronary disease that the exercise test abnormality is highly likely to be a false-positive result. Patient D has an extremely high probability of coronary disease and likely needs coronary angiography and revascularization as next steps; she does not need exercise electrocardiography because the test is unlikely to change this management plan. Patient E's care is also not likely to be influenced by an exercise test result because she is asymptomatic after major coronary revascularization surgery. Patient C has a low to moderate probability of coronary disease, and this abnormal exercise test result moves her into a mid-range probability. Thus, she is likely to undergo either further testing, initiation of antianginal therapy, or both as a result of this exercise test result.

3. Which one of the following is NOT an important consideration when weighing whether to order a test for a patient?

A. Test may influence decision making for patient's care
B. Test is less expensive than alternative strategies
C. Test is safer than alternative strategies
D. Test reduces patient's or clinician's uncertainty
E. Test is expected to be abnormal in presence of patient's already confirmed diagnosis

Answer: E Tests should be ordered when they are expected to change care and should be chosen on basis of safety, cost, and impact. They should not be ordered simply because they can confirm an already known diagnosis.

11

MEASURING HEALTH AND HEALTH CARE

CAROLYN M. CLANCY AND ERNEST MOY

Physicians routinely quantify a variety of health measures, including symptoms, vital signs, and findings on physical examination, to improve diagnosis, treatment, and prognostication. Similarly, the efficacy and quality of health care also can and should be measured for several reasons.

First, the quality of care delivered is often suboptimal.[1] Persistent variations in practice for patients with the same diagnosis reflect a combination of clinical uncertainty, individualized practice styles, patients' preferences and characteristics (age, race, ethnicity, education, income), and other factors. Both suboptimal care and varied care for the same condition undermine the historical assumption that a combination of highly trained health professionals and accredited facilities is sufficient to ensure consistent high-quality care.

A second major trend is attributable to the successes of biomedical science: the major challenge in health care today is the management of chronic disease for a population with increased life expectancy. For chronic conditions, health benefits are increasingly measured in improvements in functional status or quality of life, rather than simply using mortality rates or life expectancy.

A third trend relates directly to how the increasing costs of health care are now threatening public budgets and investments in other social goals, such as education. Although the United States spends more per capita on health care than any other developed nation (Chapter 5), the outcomes achieved lag far behind.

Finally, advances in communication and information technologies have inspired more people to play an active role in their health and health care. These innovations have accelerated demands for transparency and shared decision making.

As health insurance and health care regulation have expanded, requirements to track and justify health care services have grown. Intensifying urgency to improve the quality of health care, reduce disparities, control costs, and enhance transparency will likely lead patients and insurers to demand more data and to link quality measures to payments for services.

Fortunately, modern technology can help to meet the demand for data. Patients can record and submit their health parameters using hand-held devices connected to personal health records. Automated billing programs can track health care services, while electronic health records can assess the quality of physician care. Ultimately, fully integrated health information systems will allow patient information to be retrieved instantly and seamlessly wherever and whenever it is needed. In addition to assessing care quality today, these tools offer enormous promise for learning as a byproduct of care delivery.

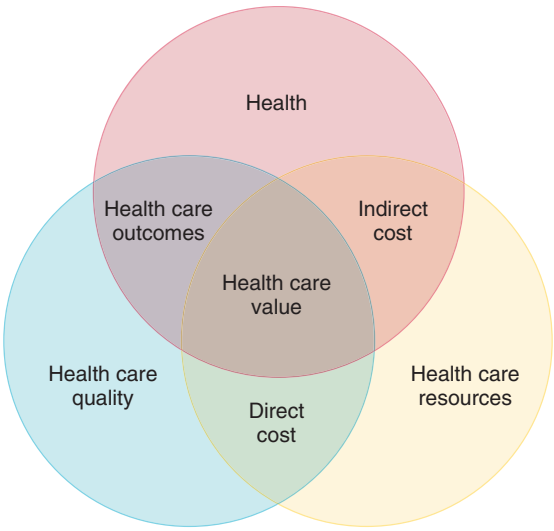
HOW ARE HEALTH AND HEALTH CARE MEASURED?

Three types of measures typically assess health and health care. Measures of *health* quantify the sickness or well-being of a person. Measures of *health care quality* quantify the extent to which a patient receives needed care and does not receive unnecessary care. Health care quality is assessed using measures of *structure* (e.g., education and credentialing of clinicians), *process* (adherence to professional standards and evidence-based recommendations), and *outcomes* (or end results of care, including how patients experience their care and their self-reported health and function). Measures of *health care resources* quantify the resources used (e.g., radiographs, surgery, medication, intensive care) to improve the health of a patient.[2] All measures can be summed up across populations within a practice or community (Table 11-1).

Measures of health and health care often overlap (E-Fig. 11-1). Health measures that can be improved by health care, such as blood pressure or blood glucose levels, are often used as health care quality outcome measures. The delivery of quality health care requires the use of resources and the generation of direct health care costs, which may or may not improve health care at the margins of spending. Impaired health that reduces the ability to do work and earn wages but that could have been prevented by the delivery of health care contributes to the indirect costs of health care. At the intersection of health, health care quality, and health care resources are measures of health care value. These measures compare the health benefits of specific health care services with their costs.[2]

WHERE DO MEASURES OF HEALTH AND HEALTH CARE COME FROM?

Most researchers, provider groups, insurers, regulators, and credentialing organizations that develop measures consult with physicians to ensure that their metrics are consistent with professional standards. Insurers may create measures to allocate health care resources, to plan for future needs, and to identify efficient physicians for inclusion on panels or to be rewarded with performance bonuses. Regulators may develop measures to establish licensure requirements and to identify physicians who might benefit from remedial instruction. Credentialing organizations may construct measures to demonstrate the superior performance of physicians who meet their high standards. For example, the National Committee for Quality Assurance maintains the Healthcare Effectiveness Data and Information Set that is widely used to accredit health plans, and the American Board of Internal Medicine and other specialty boards include measures of practice performance as well as measures of medical knowledge for the maintenance of certification.



E-FIGURE 11-1. Type of measures of health and health care.

TABLE 11-1 MEASURES OF HEALTH AND HEALTH CARE

MEASURES OF HEALTH

- *Mortality:* rates of death typically adjusted for age and sex
- *Morbidity:* incidence and prevalence rates of diseases and their sequelae
- *Functional status:* assessments of a patient's ability to perform various actions such as activities of daily living or instrumental activities of daily living as observed by a provider or reported by the patient
- *Self-reported health status:* a patients' assessment of their health and well-being

MEASURES OF HEALTH CARE QUALITY

- *Health care outcomes:* the end results or health benefits derived from good health care or the health loss attributable to poor health care
- *Health care processes:* assessments of whether the right care was delivered at the right time and in the right way
- *Health care infrastructure:* the availability of resources needed to deliver good health care
- *Patient perceptions of health care:* a patient's assessment of health care received, usually emphasizing patient-provider communication and shared decision making
- *Access to health care:* the ability of patients to gain entry into health care and navigate to needed resources

MEASURES OF HEALTH CARE RESOURCES

- *Health care utilization:* the quantity of health care services that are used
- *Direct costs:* the costs of providers, supplies, and equipment needed to deliver health care
- *Indirect costs:* the costs of lost wages and decreased productivity due to illness or injury that could have been prevented by appropriate health care
- *Nonmedical costs:* the costs of health care not related to the delivery of services, such as administration, advertising, research, and profits earned by health industries

TYPE OF MEASURE	EXAMPLE
HEALTH	
Mortality	Deaths due to colorectal cancer per 100,000 population
Morbidity	New AIDS cases per 100,000 population
Functional status	% of people unable to perform one or more activities of daily living
Self-reported health status	% of people reporting that their overall health is excellent
HEALTH CARE QUALITY	
Health care outcomes	Death per 1000 hospitalizations with pneumonia
Intermediate outcomes	% of adults with diabetes whose blood pressure is <140/80 mm Hg
Health care processes	% of children who were given all recommended vaccinations
Health care infrastructure	% of office-based physicians with computerized systems for recording clinical notes
Patient perceptions of health care	% of patients who always reported good communication with their regular providers
Access to health care	% of patients who were unable or delayed in receiving medical care
HEALTH CARE RESOURCES	
Health care utilization	% of people with an emergency department visit in the past year
Direct costs	Expenditures for the treatment of depression
Indirect costs	Lost wages and productivity while caring for children with asthma
Nonmedical costs	Profits earned by pharmaceutical companies

WHY MEASURE HEALTH AND HEALTH CARE?

Measures of health and health care can be used for many purposes by different stakeholders (Table 11-2). Patients can use their own health information to track their progress, adjust their lifestyle, and plan for their future health care needs. Patient-level measures are important to physicians, hospitals, health plans, and policymakers, whether they are used to identify sentinel events that represent quality defects (e.g., amputating the wrong leg or giving a patient the wrong medication) or to initiate root cause analyses to improve health care quality.

Hospitals and health plans aggregate measures over their practices to identify opportunities for raising quality, improving efficiency, and reducing care disparities. For measures for which physicians are primarily accountable, these data can be used to acknowledge and reward high-performing physicians, select physicians for inclusion on a panel, and produce report cards to inform the public. Patients can use these report cards to select physicians and health plans that best match their health care needs. Measures that are aggregated to the community level can help policymakers allocate health care resources to locales with the greatest need and assess the success of any interventions.

WHAT ARE THE LIMITATIONS OF HEALTH AND HEALTH CARE MEASURES?

Historically, physicians recorded information on paper and had tremendous autonomy with respect to the level of detail and accuracy. Now, however, diverse stakeholders have a shared interest in standardizing measurements to facilitate fair comparisons. Detailed chart reviews largely have been replaced by data gathered for electronic medical records and by appropriately detailed registries composed of patients with a common condition or intervention. Examples of registries that have been used as platforms for assessing health care quality include the registry developed by the Society for Thoracic Surgeons to improve the quality of cardiothoracic surgery and the National Surgical Improvement Program registry, which was initially developed within the Veterans Health Administration, to assess processes and outcomes of major surgical procedures. Both registries rely on meticulous manual data, collected by trained nurses, that facilitate professional efforts to improve outcomes of care.

SELECTING MEASURES BASED ON EVIDENCE

Data used to measure the structure, process, and outcomes of health care can be gathered as part of rigorous hypothesis-driven research or from secondary sources of data initially collected for routine clinical care billing. The data's rigor and integrity are critical to the reliability of analyses performed on them.

In addition to the quality of the data themselves, however, the method of study design is also critical to the validity of reported findings. The most robust measures are supported by the concurrence of evidence derived from different research methodologies. In randomized controlled trials, random assignment of the intervention ensures that patients who do and do not receive it are as similar as possible. In double-blind studies, neither the patient nor the patient's physician knows the assigned treatment. For more complex interventions, such as the use of a team to manage depression, blinding is impractical. In all settings, controls typically receive the best standard care. In some situations, patients may serve as their own controls in a time-series randomized trial.

Although the randomized trial is a rigorous way to assess treatment effects, enrollment is often limited to selected individuals who meet strict entry criteria. This approach enhances a trial's internal validity but limits its generalizability. As a result, randomized trials are ideal for establishing an intervention's efficacy, which is its potential benefit under ideal conditions, but not necessarily its *effectiveness* in the real world. *Cluster randomized trials*, which randomize the level of the provider or system, represent a practical approach to determining effectiveness.

Although randomized trials are critical for assessing efficacy and effectiveness, *observational* and *case-control* studies are also important. In a *cohort study*, persons or patients are followed to determine their outcomes as a function of whether or not they possess a particular attribute or have been exposed to a particular condition or intervention. Cohort studies can provide a direct estimate of the absolute risk for an outcome in exposed patients but cannot guarantee whether such differences are related to interventions that were not randomly allocated.

In *case-control studies*, cases are defined based on having experienced an outcome not experienced by controls. Information that is gleaned from existing records or interviews can determine the proportion of case and control patients who experienced an exposure of interest. Case-control studies can achieve the same or higher statistical power as cohort studies despite enrolling fewer subjects, so they are especially attractive for investigating uncommon outcomes, such as serious adverse effects of medications when the events are too rare to study with clinical trials or cohort studies. Case-control studies are subject to the misclassification bias and recall bias, and they provide estimates of relative risk but not absolute risk.

TABLE 11-2 USES OF HEALTH AND HEALTH CARE MEASURES BY USER AND UNIT OF ANALYSIS

	USES BY PROVIDERS	USES BY POLICYMAKERS	USES BY PATIENTS
Patient-level measures	Diagnosis and prognosis Monitoring treatment response and compliance	Identifying sentinel events	Tracking health and health needs Retirement and estate planning
Provider practice or health plan–level measures	Improving quality Improving efficiency Reducing disparities	Public reporting Paying for performance Provider credentialing	Selecting providers and health plans
Community-level measures	Selecting practice location	Resource allocation Policy evaluation	Selecting place to live

TABLE 11-3 ATTRIBUTES OF MEASURES OF HEALTH AND HEALTH CARE

MEASURE ATTRIBUTES	CRITERIA FOR PROVIDERS	CRITERIA FOR POLICYMAKERS	CRITERIA FOR PATIENTS
Measure is scientifically sound			
Based on strong evidence	Based on high-quality studies?		
Valid	Measures what is intended and includes key elements?		
Reliable	Reproducible by different measurers and providers?		
Clearly specified	Numerator, denominator, exclusions, and risk adjustment defined?		
Endorsed by independent experts	Well accepted by scientific and medical communities?		
Condition is important			
Affects many people Causes high mortality or morbidity Costs a lot Is very unequal across populations	Important for my practice or the population I serve?	Important for population that will be affected by my policy?	Important to me?
Data collection is feasible			
Already available Could be collected at low cost relative to potential benefit Auditable	Available for my practice or the population I serve?	Available before and after policy implementation for affected population?	Available to me?
Findings are actionable			
Can be understood Can be improved Have been used successfully Have few unintended consequences	Do I know what actions I must change to improve quality? Used in practices like mine to improve quality with few unintended consequences?	Do I know what policies I must change to improve quality? Used for policies like mine to improve quality with few unintended consequences?	Do I know what actions I must take to improve my health? Used by patients like me to improve health with few unintended consequences?
When used as part of measure set, measures are:	Represents multiple conditions, settings of care, populations, types of data (survey, administrative data, medical records), types of measures (structure, process, outcomes), and perspectives (patient, provider, system, society) as appropriate?		
Balanced Able to be disaggregated	Identifies individual measures that can be improved?		

Cross-sectional studies collect data at just one point in time. They can be used to estimate the prevalence of a condition or outcome but not to make valid inferences about whether a given outcome is related to any causal attribute or event.

There are additional methodologic issues beyond the credibility and quality of the source of data for quality measures. When presented with reports suggesting less-than-perfect performance, many physicians believe that their patients are sicker or are less likely to adhere to treatment recommendations. To address these concerns, risk adjustment for severity of illness, accurate identification of patient characteristics, and assessment of outcomes over time are all critical. Case-mix adjustment methods commonly use sophisticated statistical approaches in an attempt to adjust for such potential differences and to estimate whether observed differences result from differing patient populations rather than true differences in quality of care.

The precision of specific measures is also a challenge. Many stakeholders, especially payers and policymakers, are increasingly impatient and are generally more enthusiastic about use of measures that are only "pretty good" than are providers whose care is being judged.

SELECTING MEASURES: WHICH MEASURES ARE RIGHT FOR WHAT PURPOSE?

Creating measures is different from selecting which are most important and meaningful. Numerous publicly available sources provide a wealth of health and health care information (E-Table 11-1). The most prominent consensus-based organization that endorses measures is the National Quality Forum, which convenes panels of experts to assess the quality of a proposed measure based on criteria that include importance, scientific acceptability, feasibility, and usability. Endorsed measures are reassessed periodically to ensure they remain up to date and applicable.

The National Institutes of Health Patient Reported Outcomes Measurement Information System (http://www.nihpromis.org) is a repository of standardized patient-reported health status measures and collection instruments. Domains include physical, mental, and social well-being. The Agency for Healthcare Research and Quality National Quality Measures Clearinghouse (http://www.qualitymeasures.ahrq.gov) is an inventory of evidence-based measures of health care quality. Domains include clinical quality, efficiency, and population health. Also related are the National Guidelines Clearinghouse (http://www.guideline.gov) and the Health Care Innovations Exchange (http://www.innovations.ahrq.gov), collections of clinical guidelines and descriptions of successful uses of measures, respectively.

Potential users should examine the attributes of specific measures to ensure that they are appropriate for their intended application (Table 11-3). A number of organizations have developed scales or rating systems that summarize performance across multiple dimensions. Sometimes referred to as composite measures (e.g., a letter grade from the Leapfrog Group for hospital safety), these scales vary in comprehensiveness with little consensus regarding how components of a summary scale should be weighted. Indeed, it is not uncommon for a hospital to receive an "F" from one group and be rated a "top performer" by another. Thus, although appealing in their simplicity, the optimal use of these approaches remains unresolved.

12 QUALITY OF CARE AND PATIENT SAFETY

ROBERT M. WACHTER

During the past two decades, scores of studies have demonstrated that the quality and safety of modern health care leave much to be desired, despite the fact that most physicians are well trained and work very hard. Yet the evidence is undeniable, with clear documentation of stunning variations in patterns of care that are neither supported by evidence nor justified by outcomes, major gaps between evidence-based best practices and current practice, and staggering numbers of serious medical errors. The recognition of these quality and safety problems has catalyzed a major transformation in thinking and practice, with new technologies, regulations, training models, incentive systems, and more.

To appreciate the problem and how to address it requires an understanding of quality measurement and improvement, the safety of patients, and value, which is the confluence of safety, quality, and cost.[1]

QUALITY

Definition

Quality of care has been defined by the Institute of Medicine as "the degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge." It includes six aims for a quality health care system, emphasizing that quality involves more than the delivery of evidence-based care (Table 12-1). Nevertheless, evidence-based medicine (Chapter 10) provides much of the scientific underpinning for quality measurement and improvement.[2] Previously, the lack of clinical evidence and the apprenticeship model of medical training promoted an idiosyncratic practice style by which a senior clinician or a marquee medical center determined the standard of care—a tradition now sometimes termed *eminence-based medicine*. Without discounting the value of experience and mature clinical judgment, the modern paradigm for determining optimal practice has changed, driven by the explosion in clinical research during the past 30 years; for example, the number of randomized clinical trials grew from 350 per year in 1970 to more than 27,000 per year in 2012. This research has helped define "best practices" in many areas of medicine, from preventive strategies for a healthy 62-year-old outpatient (Chapters 14 and 15) to the treatment of a patient with acute myocardial infarction and cardiogenic shock (Chapters 73 and 107).

Donabedian triad, which divides quality measures into *structure* (how care is organized), *process* (what is done), and *outcomes* (what happens to the patient), represents the most popular construct for quality measurement. Each element of the triad has important advantages and disadvantages as a quality measure (Table 12-2). Many of the widely used quality measures are process measures for which clinical research has established a link between such processes and improved outcomes. An example is the rate at which aspirin or a β-blocker is given to survivors of a myocardial infarction before hospital discharge (Chapter 73). However, when processes are less relevant and the science of case-mix adjustment is suitably advanced (e.g., cardiac bypass surgery; Chapter 74), outcome measurement (e.g., risk-adjusted mortality rate or 30-day readmission rate) is increasingly used. In other areas involving complex processes, structural measures are used as proxies for quality; examples here include the presence of intensivists to staff critical care units, a dedicated stroke service, and computerized physician order entry systems.

TABLE 12-1 THE INSTITUTE OF MEDICINE'S SIX QUALITY AIMS

Patient safety
Patient centeredness
Effectiveness
Efficiency
Timeliness
Equity

From Committee on Quality of Health Care in America, Institute of Medicine. Crossing the Quality Chasm: A New Health System for the 21st Century. Washington, DC: National Academy Press; 2001.

The Epidemiology of Quality-Related Problems

It is now well established that there are large and clinically indefensible variations in care from one city to another. Furthermore, U.S. practice adheres to the best evidence only slightly more than 50% of the time, even when adherence is known to correlate with ultimate clinical outcomes.

Levers for Change

For physicians, policymakers, administrators, and patients, evidence of major problems with quality has led to the recognition of structural problems that prevent the delivery of the highest quality of care. These problems include the lack of information regarding the performance of a provider or institution, the absence of incentives for quality improvement, the challenge for practicing physicians to stay abreast of modern evidence-based medicine, and the absence of an information technology support system for quality.

The first step in quality improvement is the creation of practice standards against which to measure quality. Scores of such measures have been promulgated by a variety of organizations, including payers (such as the Centers for Medicare and Medicaid Services), accreditors (such as the Joint Commission), and medical societies. These measures have identified many opportunities for improvement among individual physicians, practices, and hospitals.

Given the volume of new literature published each year, it is impossible for an individual physician to keep up with all the evidence-based advances in his or her field. *Practice guidelines,* such as those for the treatment of community-acquired pneumonia (Chapter 97) or the prophylaxis of deep venous thrombosis (Chapter 81), aim to synthesize evidence-based best practices into a set of summary recommendations.[3] Although concerns about "cookbook medicine" linger, there is a growing consensus that best practices should be "hard wired" if possible. The major challenges are to update guidelines as new knowledge accumulates and to recognize the complexity of guidelines when patients have multiple, potentially overlapping illnesses. *Clinical pathways* are similar to guidelines but attempt to codify a series of steps, usually temporally (on day 1, do the following; on day 2, do the

TABLE 12-2 COMPARISON OF THREE MEASURES OF CLINICAL QUALITY: THE DONABEDIAN TRIAD

MEASURE	SIMPLE DEFINITION	ADVANTAGES	DISADVANTAGES
Structure	How was care organized?	May be highly relevant in a complex health system	May fail to capture the quality of care by individual physicians Difficult to determine the "gold standard"
Process	What was done?	More easily measured and acted on than outcomes May not require case-mix adjustment No time lag—can be measured when care is provided May directly reflect quality (if carefully chosen)	A proxy for outcomes Not all may agree on "gold standard" processes May promote "cookbook" medicine, especially if physicians and health systems try to "game" their performance
Outcomes	What happened to the patient?	What we really care about	May take years to occur May not reflect quality of care Requires case-mix and other adjustment to prevent "apples-to-oranges" comparisons

Modified from Donabedian A. The quality of care. How can it be assessed? JAMA. 1988;270:1743-1748; and Shojania KG, Showstack J, Wachter R. Assessing hospital quality: A review for clinicians. Eff Clin Pract. 2001;4:82-90.

following; and so forth), making them more useful for stereotypical processes such as the postoperative management of patients after hip replacement. As more health care delivery organizations become computerized, pathways and guidelines are often translated into *order sets* or *clinical decision support systems* to guide clinicians at the point of care.

Although professionalism (Chapter 1) should be a sufficient incentive for physicians to provide high-quality care, reaching this goal typically depends on the existence of a system organized to translate research into practice and to deliver the right care every time. Such a system requires significant investments (in educating physicians, hiring case managers or clinical pharmacists, building information systems, and developing guidelines). The historical payment system, which compensates physicians and hospitals on the basis of volume rather than quality, provides no incentive to make the requisite investments, but this situation is changing rapidly.

The Changing Environment for Quality

The recent recognition of major gaps in quality and of the need for systemic change to improve quality has led to a variety of initiatives to catalyze quality improvement. Virtually all involve several steps: defining reasonable quality measures (evidence-based measures; capturing appropriate structures, process, or outcomes), measuring the performance of providers or systems, and using these results to promote change. This final imperative creates the greatest degree of uncertainty and experimentation.

Although one might hope that simply giving a physician information about prior performance would generate meaningful improvement, this strategy yields only modest change at best. Increasingly, a more aggressive and transparent strategy, such as disseminating the results of quality measurement to key stakeholders, is being adopted. In some cases, simple transparency is the main strategy—the rationale being that providers will find the exposure of their gaps in quality to be sufficiently concerning or embarrassing to motivate improvement. Although there is little evidence that patients use such data to choose among physicians or hospitals, transparency itself has frequently resulted in impressive improvements in some publicly reported quality measures.

The newest strategy in the United States is to tie payments for service to quality performance (pay for performance, or P4P). A number of P4P programs are under way, but early results indicate that differential payment leads to surprisingly modest gains beyond the improvements achieved by simple transparency.[4,5] P4P also raises a host of concerns, including whether presently captured quality data are accurate, whether payments should go to the best performers or those with the greatest improvements, whether existing measures adequately measure quality in patients with complex diseases, and whether P4P will create undue focus on certain measurable practices, leading to relative inattention to other important processes that are not being compensated. Another concern is that an overemphasis on "extrinsic" motivation (i.e., bonus payments) can actually extinguish "intrinsic" motivation (i.e., professionalism). One variation on the P4P theme is Medicare's "no pay for adverse events" program, in which hospital payments are withheld for certain "preventable" adverse events, such as injuries from falls or health care–associated infections. As with P4P more generally, the impact of such programs on quality and safety has been surprisingly modest.

Quality Improvement Strategies

Whether the motivation is professionalism, embarrassment, or economics, the next question is how actually to improve the quality of care. There is no simple answer; successful institutions and physicians have used a variety of strategies. In general, most use a variation of a "plan, do, study, act" (PDSA) cycle, recognizing that quality improvement activities must be carefully planned and implemented, that their impact needs to be measured, and that the results of these activities are often imperfect and require retooling.

In addition to the PDSA cycle, several other types of activities are useful. For quality improvement practices that require predictable repetition, efforts to "hard wire" the practice or to use alternative providers who focus on the activity are often beneficial. For example, the best strategy to increase the rate of pneumococcal vaccination (Chapter 18) among hospitalized patients with pneumonia is to embed it in a standard order set, either paper based or computerized. Another example is that having a nurse remove patients' shoes before the physician's entry can increase rates of diabetic foot examinations in an outpatient practice (Chapter 229).

In some areas, though, quality improvement involves much more complex and interdependent activities. In these circumstances, bringing teams together to examine their practices and to participate in a PDSA cycle is the most likely path to success. For example, a group of cardiac surgeons in the northeastern United States participated in an experiment in which they observed one another's practices, agreed on best practices, and measured one another's outcomes; the result was a 24% reduction in mortality with cardiac surgery. Many health care organizations are adopting one of the more sophisticated methodologies, such as Lean or Six Sigma, which involve mapping out all of the steps of a complex process (e.g., hospital admission) in an attempt to root out waste. For a hospital or clinic, the precise methodology chosen is probably less important than the decision to adopt a single way of approaching complex processes in need of improvement.

PATIENT SAFETY

Epidemiology

The concept of "first, do no harm" began more than 2 millennia ago, and many hospitals host periodic forums (e.g., morbidity and mortality conferences) to discuss errors. Until recently, however, there has been little teaching about the nature of medical mistakes, investment in safety research, regulation of safety standards, or emphasis on safety improvements, despite the fact that an estimated 44,000 to 98,000 Americans die each year of medical mistakes—the equivalent of a jumbo jet crashing each day. Such deaths may be related to medication errors, gaps in the discharge process, communication problems in intensive care units, or retained sponges in surgical patients—in short, virtually every aspect of modern medical care. Moreover, detailed clinical and statistical evidence of suboptimal safety has been reinforced by several high-profile and disquieting errors, sometimes apparently related to inadequate supervision and prolonged duty hours of trainees. These errors include the wrong patient getting a major procedure, the wrong limb being operated on, chemotherapy overdoses, mistaken mastectomies, and more. In the past few years, new classes of errors have emerged because of poorly designed health care information systems.[6] In addition, increasing attention is focusing on areas that were previously underemphasized, such as diagnostic errors.[7]

Because patients may be harmed despite receiving perfect care (i.e., from an accepted complication of surgery or a side effect of medication), it is important to separate *adverse events* from *errors.* The patient safety literature commonly defines an error as "an act or omission that leads to an unanticipated, undesirable outcome or to substantial potential for such an outcome." Adverse events, in contrast, are injuries due to medical management rather than the patient's underlying illness. This distinction is crucial. For example, when a patient who was appropriately prescribed warfarin for chronic atrial fibrillation develops a gastrointestinal bleed despite a therapeutic international normalized ratio, an adverse event, not a medical error, has occurred. Conversely, if the international normalized ratio was supratherapeutic because the physician prescribed a new medication without checking for possible drug interactions, a medical error would have occurred.

The Modern Approach to Patient Safety

The historical approach to medical errors often has been to blame the provider who was most proximate: whoever performed the surgery, hung the intravenous medication, or mixed the chemotherapy. It is now recognized that this approach fails to appreciate that most errors are committed by hard-working, well-trained individuals, and such errors are unlikely to be prevented by admonishing people to be more careful or by shaming and suing them. Instead, the modern approach, known as *systems thinking*, holds that humans will inevitably err and that safety depends on creating systems that anticipate errors and either prevent or catch them before they cause harm. Such an approach has been the cornerstone of safety improvements in other high-risk industries for some time.

The "Swiss cheese" model of accidents, drawn from innumerable investigations of accidents in commercial aviation and the nuclear power industry, for example, emphasizes that single errors by one individual working in an otherwise safety-conscious system rarely cause harm. Instead, such errors must penetrate multiple incomplete layers of protection ("layers of Swiss cheese") to cause terrible harm. The lesson is to focus not on the futile goal of trying to perfect human behavior but rather on creating multiple overlapping layers of protection to decrease the probability that the holes in the Swiss cheese will ever align, allowing an error to slip through.

How to Improve Patient Safety

Drawing on these models, modern thinking emphasizes efforts to design and implement systems to prevent or catch errors. For example, errors in

routine behaviors can best be prevented by building in redundancies and crosschecks in the form of checklists, read-backs, and other standardized safety procedures, such as counting sponges in the operating room, signing a surgical site before an operation, or asking patients their names before administering a medication. In recent years, the use of checklists for the placement of central lines and to prepare patients for surgery has resulted in remarkable reductions in morbidity and mortality.[8] One way to decrease errors at the person-machine interface is by the use of "forcing functions," engineering solutions that decrease the probability of human error. The classic example outside of medicine is the modification of automobile braking systems to make it impossible to place a car in reverse when the driver's foot is off the brake. In health care, forcing functions include changing the gas nozzles and connectors so that anesthesiologists cannot mistakenly hook up the wrong gas, such as nitrogen instead of oxygen, and administer it to a patient. Given the ever-increasing complexity of modern medicine, building in such forcing functions in intravenous pumps, defibrillators, mechanical ventilators, and computerized order entry systems will be crucial to safety.

In addition to better systems, communication and teamwork must be improved. All commercial pilots must take "crew resource management" courses, in which they train for emergencies with other crew members, learn to flatten hierarchies that might stifle open communication, communicate clearly with standard language, and use checklists and other systematic approaches. The evidence that such interventions in medical care will improve the safety of patients is increasingly persuasive.[9] For example, better coordinated pharmacy practices can reduce medication errors after hospital discharge,[A2] and team-based approaches can reduce falls among hospital inpatients.[A3] The goal is a "culture of safety"—an environment in which teamwork, clear communication, and openness about errors, both with other health care professionals and with patients, is the norm.

Another key principle in ensuring the safety of patients is to learn from one's mistakes. Safe systems have a culture in which errors are openly discussed, often in morbidity and mortality conferences. To be most useful, these discussions should be interdisciplinary (involving physicians and other health professionals), identify when the errors occurred, and emphasize systems thinking and solutions; they should not be punitive. In addition to open discussions during conferences, safe organizations build in mechanisms to hear about errors from frontline staff, often through "incident reporting systems"; they also perform detailed "root cause" analyses of major errors or "sentinel events" in an effort to define all the layers of Swiss cheese that need improvement. The importance of open communication extends to patients as well. Disclosure of errors is now required by the Joint Commission. Patients and families value such openness, and reasonably strong evidence indicates that disclosure of errors might decrease the chance of a malpractice suit.[10]

Finally, there is increasing appreciation of the importance of a well-trained, well-staffed, and well-rested work force for the delivery of safe care. Lower nurse-to-patient ratios,[11] long work hours for residents, and lack of board certification are all linked to poor outcomes for patients. Safer systems cannot be created if the providers are overextended or poorly trained or supervised. In the United States, the Accreditation Council for Graduate Medical Education has limited duty hours for residents and has prohibited first-year residents from working 24-hour shifts. Evidence so far confirms that these standards have improved residents' quality of life but not patient safety, probably because of the concomitant increase in risky handoffs.[12]

In the absence of comparative evidence and in light of the high cost of interventions such as improved staffing, computerized order entry, and teamwork training, even institutions committed to safety must often make difficult choices. Given the natural tendency to focus on practices that are measured, publicly reported, and compensated, institutions and physicians tend to focus first on areas that are subject to regulation or on initiatives with multiple potential benefits, such as computerization. For example, computerization has been promoted in the United States by a federal incentive program, which provides billions of dollars to hospitals and physicians that implement computer systems meeting certain "Meaningful Use" standards.

Because improving culture is difficult to measure and to regulate, there is concern that it will not be as high a priority as it should be. Moreover, a safe culture depends on balancing the imperative to improve systems with the need to define and enforce accountability. The safety field is increasingly emphasizing more active enforcement of policies that address problems such as disruptive behavior by clinicians and failure to adhere to evidence-based safety practices.

VALUE: CONNECTING SAFETY AND QUALITY TO COST

Outside of health care, most purchasing decisions are based on perceived value: (quality + safety) ÷ cost. Health care decisions historically have not been made this way, in part because of the limited ability of patients and payers to make rational judgments about the quality and safety of a given provider or system, and in part because health care insurance insulates patients from the full cost of care. In the United States, which spends nearly 20% of its Gross Domestic Product on health care, policy pressures are increasingly being brought to bear on the entire value equation, that is, promoting value, not volume. For example, Medicare's Value-based Purchasing program modifies hospital reimbursement on the basis of quality, safety, and patient satisfaction scores. The organization's readmission initiative threatens substantial cuts in reimbursement to hospitals with higher-than-expected 30-day readmission rates.[13] Other federal programs seek to drive physicians and hospitals into arrangements in which they accept a fixed payment to manage a population of patients (Accountable Care Organizations) or for an episode of illness (bundled payments). Although such programs are controversial and of unproven value, they are part of a growing focus on quality, safety, the patient's experience, and the costs of care.

REVIEW QUESTIONS

1. Which one of the following is the current number of randomized clinical trials published each year?

A. 1000
B. 5000
C. 13,000
D. 19,500
E. 27,000

Answer: E Without discounting the value of experience and mature clinical judgment, the modern paradigm for determining optimal practice has changed, driven by the explosion in clinical research during the past 30 years; for example, the number of randomized clinical trials grew from 350 per year in 1970 to more than 27,000 per year in 2012.

2. Which one of the following would *not* be characterized as process measures under Donabedian triad?

A. Fraction of patients with myocardial infarction who received β-blockers
B. Fraction of patients with stroke who died within 30 days (risk adjusted)
C. Fraction of hospitalized patients with pneumonia given pneumococcal vaccination
D. Fraction of hospitalized patients with heart failure with documented predischarge instructions
E. Fraction of diabetic outpatients who received eye examinations

Answer: B Many of the widely used quality measures are process measures for which clinical research has established a link between such processes and improved outcomes. An example is the rate at which aspirin or a β-blocker is given to survivors of a myocardial infarction before hospital discharge (Chapter 73). However, when processes are less relevant and the science of case-mix adjustment is suitably advanced (e.g., cardiac bypass surgery; Chapter 74), outcome measurement (e.g., risk-adjusted mortality rate or 30-day readmission rate) is increasingly used. In other areas involving complex processes, structural measures are used as proxies for quality; examples here include the presence of intensivists to staff critical care units, a dedicated stroke service, and computerized physician order entry (CPOE) systems.

3. Which of one the following is a policy lever that has been used to promote improved quality and safety?

A. Public reporting of performance
B. Pay for performance
C. No pay for errors
D. Appeal to professionalism
E. All of the above

Answer: E The recent recognition of major gaps in quality and of the need for systemic change to improve quality has led to a variety of initiatives to catalyze quality improvement. Virtually all involve several steps: defining reasonable quality measures (evidence-based measures; capturing appropriate structures, process, or outcomes), measuring the performance of providers or systems, and using these results to promote change. This final imperative creates the greatest degree of uncertainty and experimentation.

Although one might hope that simply giving a physician information about prior performance would generate meaningful improvement, this strategy yields only modest change at best. Increasingly, a more aggressive and transparent strategy, such as disseminating the results of quality measurement to key stakeholders, is being adopted. In some cases, simple transparency is the main strategy—the rationale being that providers will find the exposure of their gaps in quality to be sufficiently concerning or embarrassing to motivate improvement. Although there is little evidence that patients use such data to choose among physicians or hospitals, transparency itself has frequently resulted in impressive improvements in some publicly reported quality measures.

The newest strategy in the United States is to tie payments for service to quality performance (pay for performance, or P4P). A number of P4P programs are under way, and early results indicate that differential payment leads to surprisingly modest gains beyond the improvements achieved by simple transparency (Jha AK, Joynt KE, Orav EJ, Epstein AM. The long-term effect of Premier pay for performance on patient outcomes. *N Engl J Med*. 2012;366:1606-1615). P4P also raises a host of concerns, including whether presently captured quality data are accurate, whether payments should go to the best performers or those with the greatest improvements, whether existing measures adequately measure quality in patients with complex diseases, and whether P4P will create undue focus on certain measurable practices, leading to relative inattention to other important processes that are not being compensated. The behavioral economics literature also warns that an overemphasis on "extrinsic" motivation (i.e., bonus payments) can actually extinguish "intrinsic" motivation (i.e., professionalism). One variation on the P4P theme is Medicare's "no pay for adverse events" program, in which hospital payments are withheld for certain "preventable" adverse events such as injuries from falls or health care–associated infections (Jack BW, Chetty VK, Anthony D, et al. A reengineered hospital discharge program to decrease rehospitalizations: a randomized trial. *Ann Intern Med*. 2009;150:178-187). As with P4P more generally, the impact of such programs on quality and safety has been surprisingly modest.

4. The "Swiss cheese model" for patient safety refers to which one of the following?

A. The importance of ensuring that the workforce is well fed and rested
B. The ability of Swiss trains and watches to run on time
C. The observation that many errors relate to the failure of multiple incomplete layers of protection
D. The inadequate incentives to promote safety
E. The tendency for computer systems to create new classes of errors

Answer: C The "Swiss cheese" model of accidents, drawn from innumerable investigations of accidents in commercial aviation and the nuclear power industry, for example, emphasizes that single errors by one individual working in an otherwise safety-conscious system rarely cause harm. Instead, such errors must penetrate multiple incomplete layers of protection ("layers of Swiss cheese") to cause terrible harm. The lesson is to focus not on the futile goal of trying to perfect human behavior but rather on creating multiple overlapping layers of protection to decrease the probability that the holes in the Swiss cheese will ever align, allowing an error to slip through.

5. Which one of the following would be an accurate equation to capture health care "value"?

A. Quality × safety ÷ patient satisfaction × cost
B. Quality ÷ patient satisfaction × cost × safety
C. Cost ÷ quality
D. Quality × safety × patient satisfaction ÷ cost
E. Quality × cost ÷ patient satisfaction

Answer: D Outside of health care, most purchasing decisions are based on perceived value: (quality + safety) ÷ cost. Health care decisions historically have not been made this way, in part because of the limited ability of patients and payers to make rational judgments about the quality and safety of a given provider or system, and in part because health care insurance insulates patients from the full cost of care. In the United States, which spends nearly 20% of its Gross Domestic Product on health care, policy pressures are increasingly being brought to bear on the entire value equation ("promoting value, not volume"). For example, Medicare's Value-based Purchasing program modifies hospital reimbursement based on quality, safety, and patient satisfaction scores.

COMPREHENSIVE CHRONIC DISEASE MANAGEMENT

EDWARD H. WAGNER

The World Health Organization defines chronic disease as "health problems that require ongoing management over a period of years or decades." This definition encompasses a broad array of physical, mental, and behavioral health problems. Regardless of cause or pathophysiology, chronic conditions require ongoing attention and adjustments by patients and their loved ones as well as care by professionals. Improving care for chronic illnesses has been facilitated by the realization that individuals with a wide variety of chronic health problems have similar needs to minimize morbidity and to optimize quality of life (Table 13-1). Because these needs are shared across conditions, clinical management of these seemingly disparate illnesses requires similar practice capacities and functions. The design and organization of care that leads to better outcomes are remarkably similar for conditions as clinically different as diabetes, depression, and substance abuse disorders.

To live effectively with their health conditions and to manage their treatments, patients must have access to essential information, skills, and encouragement. They must also receive evidence-based therapy and preventive care over time to improve disease control and to reduce the risk of complications and exacerbations. Because chronic illnesses are rarely cured and often change over time, effective care involves continuous monitoring and adjustments by patients and caregivers alike. When chronically ill patients experience periods of increased severity and risk, they often benefit from an intensification of management and support. Care for the chronically ill generally involves multiple health professionals and care settings, and it must be coordinated effectively.

TABLE 13-1 COMMON NEEDS OF PATIENTS WITH CHRONIC ILLNESS

Support and information that enables patients to be competent self-managers of their health and illness
Effective clinical and behavioral treatment that keeps the condition under control and optimizes health status
Effective preventive care to reduce the risk of complications and other morbidity
Ongoing monitoring of the patient's condition to detect and to respond to problems early in their course
Intensification of management and support during high-risk periods
Coordination of care to increase the efficiency and effectiveness of referrals and to prevent the mishaps that commonly occur during care transitions

THE GOALS OF CHRONIC CARE MANAGEMENT

The goals of chronic care management are to meet the aforementioned needs of patients with chronic illness routinely and efficiently. Chronic conditions, whether medical or psychiatric, present challenges for patients and their caregivers very different from those of acute illnesses or injuries. The decisions and behaviors undertaken by patients to deal with their illness, generally called self-management, influence the course and outcomes of most chronic diseases in major ways. Patients make decisions and take action in dealing with symptoms, coping with the social and emotional impacts of illness, monitoring their condition, taking medications, adjusting lifestyle, and interacting with the health care system. Most need training and ongoing support to become competent managers of their health and their illness. The competence and confidence with which patients self-manage have a major impact on outcomes. For example, participants in diabetes or hypertension self-management training programs generally experience clinically significant reductions in hemoglobin A_{1c} or blood pressure levels without major changes in drug therapy.■ Self-management can be enhanced in patients of all socioeconomic groups by empowering, training, and supporting them. Modern self-management support is a collaborative rather than a didactic process that seeks concordance between providers' and patients' perspectives on the goals of treatment and the actions needed to reach those goals.[1]

Whereas the primary goals of acute disease care are cure and recovery, cure is not an option for most chronic diseases, which are often characterized by slowly progressive deterioration, even with excellent care. Nevertheless, control of the metabolic or physiologic abnormalities or symptoms resulting from the underlying pathophysiologic processes (disease control) is now possible for most chronic conditions. Drugs and other therapies attempt to minimize morbidity, to limit further organ damage, to reduce the risk of exacerbations and complications, and to maintain quality of life and function. The metabolic or physiologic abnormalities or symptoms used to assess disease control often serve as clinical targets to guide therapy and as performance indicators to monitor the progress and quality of care for populations of patients (e.g., the percentage of diabetic patients with blood pressure <130/80 mm Hg). Disease control for many conditions requires the rigorous application of evidence-based treatment protocols that carefully step up or intensify treatment until clinical targets are reached.■

Ongoing monitoring and assessment of chronically ill patients are essential to optimize treatment and to prevent losses to follow-up. Regular review of self-management activities reinforces their importance to the patient and to the overall management of the condition. Serious exacerbations and complications of common chronic illnesses are potentially preventable if they are identified early in their course and treated appropriately (e.g., recurrence of major depression, opportunistic infection in patients with HIV, foot ulcers among diabetic patients). The periodicity of assessments must change as the severity of illness waxes and wanes over time.

An increasingly important goal of effective chronic care management is to provide more intensive monitoring and management during periods of high risk, such as transitions from hospital to community or exacerbations. Clinical care or case management by nurses, pharmacists, or other nonphysician health professionals enables closer monitoring of patients, helps with medication adjustment, provides self-management support, and facilitates care coordination. Effective care management programs can reduce the likelihood of rehospitalization for chronically ill patients discharged from the hospital, reduce emergency department visits and hospitalizations among multiproblem ambulatory older adults, and improve disease control.

Chronically ill patients frequently receive medical and supportive services from multiple providers in different settings. Without good coordination, unnecessary hospital readmissions and emergency department visits, gaps and inefficiencies in care, and distress of the patient are all too common. Without assistance from their primary providers, patients or their loved ones must often assume responsibility for the onerous task of coordinating care.

MATCHING PATIENT NEEDS AND CARE DELIVERY

The percentage of chronically ill patients in good control varies widely from practice to practice, even after adjustment for patient differences. When individual practices are audited, failures to follow evidence-based guidelines or losses to follow-up appear almost randomly across different interventions and among patients within a practice, suggesting that they are related to flaws in care systems rather than to cognitive gaps. What, then, distinguishes practices that have high rates of control of major chronic conditions from the majority with much lower control rates?

Ambulatory care systems have for centuries been organized to react to acute problems, not to address the ongoing needs of the chronically ill. The focus on making a diagnosis and initiating treatment for the problem at hand leaves little time for addressing less urgent needs, such as medication adjustment, self-management support, and preventive care. Reimbursement systems that favor multiple short encounters aggravate the problem.

Failure to adhere to evidence-based guidelines and insufficient follow-up and attention to patient self-management are largely responsible for the poor control of chronic illness. The guidelines for most chronic conditions include recommendations to step up or to intensify therapy when clinical targets are not reached. Failure to intensify treatment in patients who have not achieved therapeutic targets, called clinical inertia, has been found in a large percentage of patients with uncontrolled diabetes, hypertension, depression, and other chronic illnesses. Clinicians have an understandable reluctance to increase drug doses or to add new drugs, but concerns about toxicity or nonadherence of the patient can be mitigated if practices have organized approaches to stepping up therapy and closely monitoring its impact.

Deficiencies in practice infrastructure and the professional environment compound the difficulties of meeting the needs of chronically ill patients. Despite electronic medical record systems, many practices still have difficulty in managing patient populations or measuring the quality of their care. Primary care physicians are increasingly uninvolved or even unaware when their patients are hospitalized. Efforts to improve the quality of chronic care must focus on improving the infrastructure and practice systems that busy clinicians require to meet the needs of their patients.

Interventions That Improve Care and Outcomes of Chronic Diseases

A wide array of systemic changes can improve the care and outcomes of major chronic diseases. These changes fall into four general categories. *Patient-directed interventions* try to enhance the knowledge of patients, increase their involvement in care, and alter their behavior. *Provider-directed interventions* give providers feedback about the quality of their care and try to change providers' knowledge and behavior through education and reminders. *Organizational changes* generally focus on the composition and functioning of the care team, the organization of patient encounters (e.g., planned visits), and the management of patients outside the office (e.g., follow-up, care management, and care coordination). *Information technology interventions* include the use of registries, computer reminders, and other decision support programs for management of populations and patients. Growing evidence suggests that the use of patient databases (registries) to measure performance, to identify individuals needing care, and to plan care of individual patients may be the information technology function that contributes the most to improving the care of the chronically ill.

Provider-directed interventions, especially educational programs, generally demonstrate weak effects. Conversely, interventions that promote the patient's self-management and change the composition or functioning of the practice team have the most salutary effects.■■ Across conditions, assigning responsibilities for care of patients to the nonphysician members of practice teams consistently leads to significant improvements in evidence-based care processes, disease control, and other outcomes. Better informed patients have better outcomes when they receive care from more informed providers who are supported by a well-organized clinical team and appropriate information technology.

The Chronic Care Model

Developed in the late 1990s, the chronic care model summarizes the basic elements for improving care of chronically ill individuals (Fig. 13-1). This

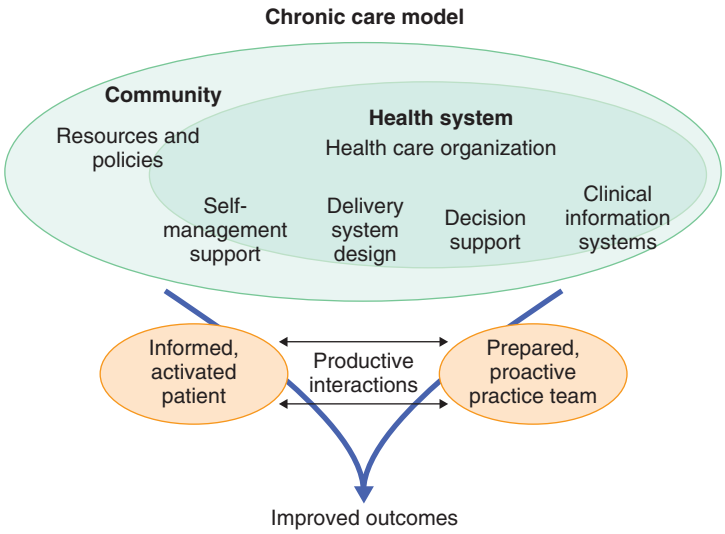

FIGURE 13-1. The chronic care model. (Modified from Wagner EH. Chronic disease management: what will it take to improve care for chronic illness? Eff Clin Pract. 1998;1:2-4. Chronic Care Model © American College of Physicians, Annals of Internal Medicine.)

model identifies six features of a health care system that facilitate high-quality chronic disease care: self-management support, delivery system design, decision support, clinical information systems, health care organization, and community resources. Evidence-based changes in these six areas foster productive interactions between informed patients who take an active part in their care and practice teams organized to meet their needs.

The chronic care model presumes that chronically ill patients have a primary care clinician, either a generalist or a specialist, who assumes responsibility for managing their care and coordinating the activities of other clinicians and institutions that provide advice and services. It posits that important patient outcomes, such as the prevention of morbidity, mortality, and avoidable emergency department visits and hospitalizations, can be affected by productive medical care. Accumulating evidence indicates that implementing the elements of the chronic care model is associated with improvements in the care and outcomes of chronic diseases.[1] Productive interactions are more likely when patients actively participate in their care. To do so, patients benefit from having the relevant information and skills needed to manage their illness as well as ongoing support and encouragement to overcome denial and passivity.

The other partner in productive interactions is the primary care clinician and the practice team. Before visits with chronically ill patients, practice teams should review accessible information to determine what services are needed, have clear assignments or standing orders for the delivery of those services, and include staff trained to perform them. Although all six elements of the chronic care model contribute to a delivery system that can effectively manage chronic illness, changes in two categories—delivery system design and self-management support—are essential to improve disease control and to reduce morbidity and mortality.

Self-Management Support

Didactic education of the patient alone has been demonstrated to have little if any impact on the patient's behavior or disease control. To change their lifestyle, to take medications as directed, to deal with symptoms and stress, and to address the other challenges of living with chronic illness, patients need to participate actively in their care, to understand and agree with the clinician's assessment of the problems and recommendations, and to learn the skills needed to carry out the recommendations. More active patients are more likely to engage in relevant self-management behaviors and to use health care more effectively,[2] so patients should be empowered to take an active role in their health care.

Group and individual interventions can help patients understand their illness and its treatment and give them the skills and confidence needed to be competent self-managers. In general, these programs share common features that include the teaching of critical skills (e.g., self-monitoring, use of medications), the collaborative development of realistic goals, and action plans for meeting these goals. Although self-management courses facilitated by peer or professional leaders improve disease control in diabetes, hypertension, and other chronic diseases, their effects diminish after termination of the program, so sustained follow-up and reinforcement are essential. Long-term self-management support is best accomplished by the primary care team in the context of ongoing chronic illness care. Although a physician's advice and encouragement are important, most primary care clinicians have neither the time nor the training to help patients set behavioral goals, to develop action plans, and then to follow up by telephone or e-mail. Clinical staff such as nurses or medical assistants with good communication skills and additional training in counseling methods can and should perform these functions.

Delivery System Design

Team Care

The goal of delivery system design is to match the organization of care delivery to the needs of the chronically ill. Without the help of a team, it is unlikely that physicians, in the course of a 15- to 20-minute visit, can effectively manage intercurrent problems, review and adjust treatment, provide recommended assessments and preventive care, discuss self-management goals and plans, and plan follow-up. Designing effective team care begins with a consideration of the various tasks required to meet the needs of the chronically ill and to ensure adherence to guidelines. Key tasks are allocated to the most appropriate members of the practice team. The team's routine involvement in patient visits is facilitated by protocols or standing orders that guide independent action by nonclinician staff. Brief meetings, often termed huddles, before clinic sessions allow practice teams to review key data (often from registries) of scheduled patients, to identify needed services, and to plan their delivery. The goal is to maximize the productivity of every patient interaction.

The specific practice change associated with the largest improvements in chronic disease outcomes is the increased involvement of the nonprovider members of practice teams in meeting the patient's clinical care needs.[3,4] For example, a recent trial showed that adding briefly trained lay "care guides" to primary care teams significantly increased the likelihood that patients would achieve disease-specific goals, such as diabetic retinal examinations and effective blood pressure control.[5]

Planned Interactions

Much of chronic care management involves predictable preventive care or disease management activities, which are often postponed when chronically ill patients seek care for an acute problem. The availability of key patient data gives practice teams the opportunity to update chronic illness care even during visits for more urgent problems. Armed with information from an electronic medical record's reminder systems, nonphysician staff can provide flu shots, diabetic foot examinations, and other evidence-based actions. Practices also can initiate planned visits for patients who are noncompliant with guidelines, have failed to reach treatment targets, or have been lost to follow-up. Another format for the delivery of planned care is the group visit, in which patients receive their primary medical care together as a group. Group sessions generally include the same check-in activities that occur during an individual visit, followed by brief individual communications between the primary care provider and each patient, opportunities for private consultations, and an educational session with ample opportunity for peer-to-peer interaction. Approximately 30 to 50% of patients offered group visits attend them, and many prefer to receive much of their care in this setting.

Follow-up and Case Management

Follow-up tailored to a patient's needs and the clinical severity of the disease is a critical component of effective chronic care management. Traditionally, follow-up consisted of periodic in-person physician visits whose frequency is limited by cost and convenience. Ample evidence indicates that follow-up by telephone, e-mail, or telemedicine can be cost-effective and far more flexible than total reliance on repeated face-to-face return visits. Nonphysician team members, guided by protocols with clear referral criteria, can effectively manage much of electronic follow-up. Self-monitoring by patients is an important component of the follow-up plans for many chronic illnesses and is especially useful when patients use the results to adjust their therapy[6] as well as to inform their practice team. Collecting self-monitoring data for the sole purpose of bringing them to the physician's office appears to be far less effective.

Chronically ill individuals at high risk of hospitalization, nursing home placement, major complications, or death often experience periods when more intensive monitoring and management would be helpful. Less severely

ill patients also need closer follow-up during exacerbations or intercurrent illnesses, after hospital discharge, or when medications are being titrated or changed. Severely ill patients commonly have multiple chronic conditions, which often are complicated further by depression and other psychosocial problems. In response to these needs, nurse care management programs that regularly communicate with patients electronically or in person have proliferated. These programs assess a patient's status, review and support self-management goals and action plans, help coordinate care among providers and care settings, and may help manage medications. Case management is more likely to be effective if the case manager collaborates closely with the primary care clinician, has specific management goals (e.g., improve disease control or improve function), influences the medication regimen directly or indirectly, and reviews his or her caseload regularly with clinician experts.[3,4]

Decision Support

Efforts to educate health professionals have a limited impact on clinical performance. Inserting information and alerts directly into the flow of decision making is more helpful, although "alert fatigue" has become a serious problem. Even the most carefully developed evidence-based guidelines will have no impact on practice if they are not integrated into clinical management through computer templates, alerts, protocols, standing orders, and other efforts to standardize practice.

Many chronically ill patients who are cared for by generalists benefit from the advice and involvement of medical specialists. Truly shared care involving interactive communication between primary care clinicians and specialists can improve outcomes.[A10] Interactive communication channels between generalists and specialists (Chapter 430) can be improved by creating systems whereby consultants respond to questions by secure messaging within an electronic medical record system or through a web-based referral system.

Clinical Information Systems

Well-maintained registries that are either independent or incorporated in an electronic medical record enable practices to identify patients who need additional services, to produce rapid summaries of key clinical data and services for future patient encounters, and to measure clinical performance. Registries allow practices both to monitor and to manage their chronically ill populations. For example, individuals overdue for important preventive interventions or who fail to keep appointments can be efficiently identified and contacted.

Electronic two-way communication between patients and providers is playing an increasing role in the management of chronic disease. Telehealth, web portals, and mobile device applications enable providers to obtain and to respond to clinical data from patients, and they give patients efficient mechanisms for addressing their questions and concerns.

Community Resources

Programs and organizations in patients' local communities can most effectively meet many of their needs. Such needs include transportation, homemaker services, smoking cessation (Chapter 32), exercise (Chapter 16), weight control (Chapter 220), peer support, caregiver support and respite, self-management training, and financial counseling and assistance. For commonly needed services, practices should at least be able to provide specific information to advise patients on their best options.

TRANSFORMING PRACTICE

Measures of disease control and other indicators of the quality of chronic care begin to improve only when practices have made system-wide changes in most of the elements of the chronic care model, such that the routine care of all their chronically ill patients has been affected.[5] Practice routines and culture must change in ways that are initially foreign and uncomfortable for many practitioners. Team care means more meetings, new roles, and additional training for staff. To have useful registries and to provide proactive care, busy practices must define their population of patients and learn to manipulate software and data to obtain the information they need. Some of the changes may require additional financial investment. For all these reasons and more, improving chronic care management requires highly motivated physicians and practices that actively engage in continuous quality improvement. Practices must develop approaches that fit their population of patients, resources, and practice style, and they must refine and adapt them using rapid cycle improvement methods.

Health Care Organization

Many practices caring for chronically ill individuals are parts of larger health care organizations that can either encourage and promote the improvement of chronic care or undermine and obstruct it. Helpful organizations promote continuous quality improvement, incorporate a trusted performance measurement system, and provide financial or nonfinancial incentives for high quality.

REVIEW QUESTIONS

1. An obese patient with type 2 diabetes consistently has HbA1c levels above 10%. There is strong evidence that he is not following diet or exercise recommendations. He has recently attended diabetes education classes at the local hospital. Which of the following is the most appropriate next step?

A. Collaboratively establish realistic goals and an action plan and monitor closely.
B. Remind him of the dangers of uncontrolled diabetes.
C. Increase his medications.
D. Refer him to a diabetologist.

Answer: A It is highly likely that this gentleman's poor diabetes control is heavily influenced by his poor self-management. Before changing or increasing drug therapy, it would be most appropriate to have him spend time with someone (preferably in the practice) trained to use effective counseling methods like motivational interviewing to try to motivate him, develop achievable behavioral goals and a realistic action plan, and then follow him closely.

2. A physician receives performance metrics about her care of diabetes and hypertension. She is disappointed to find that her measures are below the average for her practice, even for simple things that she thought she was diligent about—for example, flu shots and regular HbA1c testing. She can't work any harder. Which of the following is the most appropriate next step?

A. Increase the time allotted for visits by diabetic or hypertensive patients.
B. Try to increase the involvement of her medical assistant and other available staff in the performance of evidence-based care.
C. Hire a nurse to manage routine diabetes and hypertension visits.
D. Add more frequent alerts to her EMR.

Answer: B There is considerable evidence that the involvement of all members of the practice team in meeting patient needs is the intervention that leads to the largest improvements in the delivery of evidence-based services and disease control for hypertensive and diabetic patients. Medical assistants and LPNs can review patient records before visits to identify needed services and, with standing orders, perform all those functions that state regulations allow. They can also be trained to provide self-management support.

3. Local health plans are providing performance bonuses to practices that can demonstrate reductions in their readmission rates for chronically ill patients. Which of the following is most likely to help a practice reduce their readmission rate?

A. Have practice clinicians make hospital rounds.
B. Tell patients to call for an appointment after discharge.
C. Hire and/or train a nurse care manager in the practice to work with recently hospitalized patients.
D. Ask hospital discharge planners to alert the practice that their patient is ready for discharge.

Answer: C Hospital readmissions can be reduced by ensuring timely, coordinated, and appropriately intensive post-hospital care. Hospitals often don't or can't identify a patient's primary care provider, so community practices must proactively try to identify hospitalized patients and make certain that they receive appropriate follow-up care. A care manager working in or closely with primary care is the best option.

4. Major depression is a common problem seen primarily in primary care. A practice is trying to develop local guidelines for the management of patients with this condition. They are trying to take into account the evidence of effectiveness as well as patient preferences and costs. Which of the following is the best strategy for them to employ?

A. Refer all patients either to a psychiatrist or therapist depending on patient preference.
B. Refer patients that don't respond to initial therapy to a mental health provider.
C. Give all patients a trial of antidepressant medication.
D. Identify a mental health provider consultant and care manager within to practice to help the primary care physicians manage the patients.

Answer: D There is very strong evidence that collaborative care models are superior to other ways of managing depressed patients in primary care. These models include ensuring that primary care physicians understand treatment guidelines, that staff in the practice are trained to provide follow-up assessments for depressed patients, and that a mental health provider is available to provide information and support to the primary care physician or care manager, and to see patients if necessary.

COUNSELING FOR BEHAVIOR CHANGE

F. DANIEL DUFFY

Most medical care requires patients to change some behavior. For example, patients may need to keep appointments, stop an addictive behavior, eat different foods, take daily medications, monitor glucose levels, or increase their physical activity. The probability of effectuating change depends on the skills and language of the counselor, recognizing that clinicians typically see patients during brief and relatively infrequent visits for prevention and chronic care.

Behavior change counseling is talk therapy that engages patients in a partnership to execute a plan for change.[1] Behavior change counseling delivered by trained counselors is efficacious in sustaining healthy diets, increased physical activity, reduced alcohol and tobacco use, improved dental outcomes, reduced body weight, and self-care monitoring. Trained physicians who provide brief office-based counseling using patient-centered motivational methods can help patients successfully lose weight and improve diabetes self-care management. Modest success has been achieved with office-based counseling for medication adherence but not for heavy drinking or problem drug use.

MOTIVATIONAL INTERVIEWING

Motivational interviewing is an evidence-based therapy that has been adapted to the clinical setting to counsel patients about behavior change.[2] Using this approach, clinicians avoid giving advice and instead ask open-ended questions and then use "reflective listening" to uncover internal ambivalence that may restrain change. The verbal behaviors of trained clinicians include listening carefully and responding to patients' voiced desires, fears, and ambivalence about changing; using statements to affirm patients' autonomy and ability; summarizing patients' self-arguments for and against change; and helping patients intensify their motivation to make changes. With persistence, these conversations can convert patients' ambivalence into the belief and confidence that they can and will change. The overall advantage of motivational interviewing is about 50% greater than comparative counseling methods.[3]

Change counseling in medical care is based on the transtheoretical model of change (Fig. 14-1), which proposes that people change by moving through a cycle of five cognitive-experiential stages (Table 14-1): *precontemplation*, *contemplation*, *determination*, *action*, and *maintenance*,[4] often with a sixth stage (*relapse*). Many people cycle several times before adopting a new habit. By identifying a patient's stage along this continuum of change, a physician can select the most efficient counseling approach.

FITTING CHANGE COUNSELING INTO MEDICAL PRACTICE

The goal of change counseling is to help patients do what they need to do to achieve their own health goals. Physicians help but cannot make people change. Patients do the work, guided by clinicians who evoke their internal motivation to make the change.

To learn what behaviors patients need to change, the physician starts by taking a history of active problems, by performing an appropriate physical examination (Chapter 7), and by ordering any indicated diagnostic tests (Chapter 10). To optimize motivational interviewing, the history should rely primarily on open-ended questions so patients can tell their own stories. The physician's periodic reflections, expressions of empathy, and summaries of what patients say help patients believe they can and must change.

THE ASK-TELL-ASK APPROACH

The process of change counseling helps patients focus on their role in achieving their own health goals. In contrast to a paternalistic practice of making a diagnosis, ordering treatment, and giving expert advice, it promotes a patient's motivation, autonomy, and responsibility for making changes.

Iterative *ask-tell-ask* cycles remind clinicians first to *ask* patients to engage; second to *tell* information, answer questions, and correct misinformation; and third to *ask* patients to verbalize their understanding and intentions.

To use the ask-tell-ask strategy to initiate a conversation about the diagnosis and treatment, clinicians first ask permission to summarize their findings. Second, if patients agree, clinicians tell their diagnostic impressions and health assessments using clear and simple language. Third, clinicians ask an engaging follow-up question to clarify patients' understanding with a question such as, *What do you know about this situation*? The third ask may take the form of a reflective statement that invites patients to go deeper, affirm their courage, express empathy, or acknowledge nonverbal expressions of emotion. Usually, people know more than expected, thereby reducing the time needed for education of the patient.

To focus patients' attention on their role in making changes, clinicians might ask, *What ideas do you have about what you and I might do to improve your health*? Generating a list of hypothetical options may take several ask-tell-ask iterations. When a satisfactory list has been developed, the physician should summarize the patient's voiced health goals and the shared list of options for achieving them.

Clinicians then initiate change planning with a question such as, *What are you willing to do*? Patients' answers indicate their readiness to take action to change their behavior. Clinicians should guard against the "expert trap," in which patients skirt their own ambivalence for change and shift responsibility for change onto the clinician by stating, *You are the expert, and I'll do whatever you tell me to do.*

To avoid the trap, clinicians can estimate patients' motivational stages using a *conviction-confidence ruler* (Fig. 14-2). Clinicians show patients a ruler with markings from 1 to 10 and ask, *How convinced are you that it is important for you to do what is needed from 1 (not convinced at all) to 10 (totally convinced)*? They then ask, *Using the same scale, how confident are you that you will do it*?

Patients with low (0 to 2) scores are probably in the precontemplation stage. Midrange scores (3 to 7) suggest the contemplation stage. A high conviction score (8 to 10) implies determination to change, and moderate to high confidence scores (5 to 9) imply the preparation stage. High scores for conviction and confidence indicate action or maintenance stages. In the relapse stage, patients may have a low confidence score and, if very discouraged, a low conviction score as well. Scores of less than 7 on either question may indicate insufficient motivation for success.

The conviction-confidence scale can clarify patients' convictions about the importance of changing by asking, *Why four on conviction (or confidence) and not lower*? Or one might ask, *What would it take to raise your conviction (or confidence) score to a nine*? Voiced answers to these question help patients clarify their values and beliefs and see their strengths and resources to make needed changes.

STAGE-SPECIFIC CHANGE COUNSELING

A patient-centered change plan is far more comprehensive than a medical treatment plan, which forms only one part of a person's health plan. For example, filling a prescription is one step in a treatment plan, but remembering to take the medication several times a day, altering eating habits, monitoring medication effects, and quitting a self-destructive behavior are ongoing tasks in a change plan. The most common error in medical care is treating lifestyle changes as a simple prescription and being disappointed with the lack of patient adherence to recommendations. Nevertheless, physicians often must first focus the change plan on ensuring that patients take their medications before addressing more complex and time-consuming lifestyle changes.

Precontemplation stage counseling encourages patients to seek information from reading material and websites and to talk with family, friends, or others who have successfully made similar changes. This process highlights the conflict between the risks of the status quo and the benefits of new lifestyle behaviors. Precontemplation is not influenced by scare tactics, professional argument, or debate.

Contemplation stage counseling, which is more difficult, requires time and training. Trained physicians or counselors help patients explore and resolve the natural ambivalence that keeps them from doing the work needed to change. A *decisional balance table* (Table 14-2) can contrast a patient's reasons for sustaining current behaviors with the reasons for changing to healthier ones. Clinicians or counselors listen to what patients say and verbally reflect a patient's ambivalence to help patients begin to convince themselves to change. This approach helps patients "think out loud" about their conflicting desire to change and their simultaneous wish to sustain the status quo.

When momentum stalls or patients backslide from doing their part, physicians often blame patients for resisting change or label them noncompliant. More likely, the difficulty lies with insufficient resolution of the natural ambivalence about change and evolving discord in the physician-patient relationship. Physicians and patients begin talking at cross purposes, become

TABLE 14-1 STAGES OF CHANGE CHARACTERISTICS

STAGE OF CHANGE	PATIENT RESPONSE	PATIENT CHANGE TASKS	CLINICIAN COUNSELING TASKS	COUNSELING RESOURCES
Precontemplation	Surprise about problem Not thinking about changing Demoralized if in relapse	Learn about condition and change needed Develop self-awareness	Reflective listening Advise Inform	Information media Self-assessment logs or diary
Contemplation	Ambivalence Change talk—concern about health risks Sustain talk—prefers the status quo	Self–re-evaluation Raise conviction of importance of change Raise confidence in ability to change	Empathize with patient's ambivalence Open questions Affirm the positive Reflective listening Summarize patients' talking themselves into change	Conviction-confidence ruler Decisional balance Feedback logs Role models Referral for group training
Determination	I must change I can do it	Raise importance Raise confidence Develop action plan Pick start date Tell others	Support self-efficacy Facilitate action plan Anticipate problems Encourage social support	Menu of options Referral for formal counseling List of role models
Action	What will I do? Who or what might help? What problems might I have?	Take action steps to change Manage withdrawal from addiction	Manage cues to old behavior Be alert to positive effect of new behavior Reward self for change Manage withdrawal	Written plan Menu of cues Menu of consequences Menu of rewards Refer for counseling
Maintenance	Pleased with changed self Spontaneous talk about success and difficulties	Manage cues to go back to old behavior Manage bad effects of the new behavior Seek and use social support for change Become a role model to others	Discuss signs and times of danger for relapse Discuss "relapse thinking" Affirm new lifestyle habits	Role model for others Social support sources Referral for maintenance counseling
Relapse	Tells about thinking old behavior was no longer a concern Loss of control Demoralization	Learn the antecedents of relapse Recognize "relapse thinking" Keep open, do not hide Call for help	Reframe relapse to be a valuable lesson Evoke self-efficiency Move quickly back into action	Refer for formal relapse counseling Encourage finding role models who made change Frequent follow-up

Not at all convinced	0	1	2	3	4	5	6	7	8	9	10	Totally convinced
On a scale of 1–10, how *confident* are you that you have the ability to change … *(Name the behavior)* … ?"												
Not at all confident	0	1	2	3	4	5	6	7	8	9	10	Totally confident

FIGURE 14-2. Motivational counseling aid.

TABLE 14-2 DECISIONAL BALANCE

BEHAVIOR	REASONS NOT TO CHANGE	REASONS TO CHANGE
Unhealthy behavior	What do you like about it?	What are your concerns about it?
Healthy behavior	What are your concerns about it?	What do you like about it?

defensive, blame, interrupt, and disengage. Physicians might resolve the relational discord with an apology, by affirming patients' strengths, or by shifting the focus of counseling to empathy with the patient's ambivalence and encouragement to believe that she or he can change.

Determination and action stage counseling reinforces a patient's confidence. Counseling might begin with the question, *What are you going to do and when will you begin?* Picking a start date and committing to other people generates accountability and social support. Because it is difficult to change alone, asking *Who or what might help you?* encourages patients to solicit support from partners or others who are making similar changes. Patients may use reminders and rewards to reinforce the new behavior while avoiding situations that stir craving for the old behavior. To plan for relapse prevention and recovery and to handle problems and side effects, clinicians might ask, *What problems might arise and how might you handle them?* As with all change counseling, action plans work best when patients identify the people, resources, and coping strategies themselves. When the change involves quitting an addictive behavior, the plan also should include treatments to manage withdrawal and craving (Chapters 32, 33, and 34).

Maintenance stage counseling is frequently ignored on the assumption that once patients take action to change, the work is done. Moving from action to maintenance requires the new behavior to be internalized and to become routine, requiring little thought or effort. Counseling bolsters the new behavior when "change boredom" sets in, life stresses and competing priorities weaken commitment, or old behaviors become attractive and their consequences forgotten. Maintenance counseling keeps vigilance alive with

questions such as, *What is working*? or *Most people have difficulty; how has this change gone for you*? Physicians can talk about relapse with questions like, *Many people begin to think that after a while it's safe to . . . [return to the old habit] just one more time; if you have had these thoughts, how have you handled them*? To engage patients in creative problem solving, physicians might ask, *Who or what has helped you sustain your new behavior*? Planning for recovery after a lapse can be initiated by asking, *Should you slip, what will you do, or who will you call*? A suggestion to call immediately tells patients that relapse is common and can be remediated; it should not be considered a sign of failure. By reframing relapse as a learning opportunity, physicians also help patients reflect on how to strengthen their action plan.

COUNSELING TEAMWORK AND REFERRAL

Behavior change counseling helps patients move from precontemplation to maintaining new habits. This counseling is not a single intervention but rather an ongoing process with long-term follow-up at frequent intervals. Longer counseling visits are appropriate in the first few months for the precontemplation and contemplation stages. Face-to-face or telephone follow-up visits every week or two are useful during the determination and action stages. For the maintenance stage, monthly brief follow-up counseling in the office combined with almost daily contact with supporting persons or role models works well. When intensive help is needed, physicians may refer the patient to education classes, behavioral counseling professionals, or self-help support groups to augment the medical treatment. Medical home primary care practices also can provide counseling for proactive prevention and chronic illness care using multidisciplinary teams of nurse educators, nutritionists, physical therapists, psychologists, and pharmacists. Changing of addictive behaviors usually requires referral to a behavioral change specialist.

REVIEW QUESTIONS

1. Which of the following statements best describes the purpose of change counseling in the context of medical care?

A. To evoke patient self-motivation and to resolve ambivalence about changing
B. To advise patients of the evidence-based changes that are best for their health
C. To affirm and to support the autonomy of patients regardless of whether they change
D. To make patient-centered arguments to convince patients to change
E. To create a safe supportive environment that encourages patient change

Answer: A The principles of change counseling emphasize the importance of goal-directed counseling that ends in the patient's moving toward more healthy behaviors. The approach uses conversational counseling methods that evoke the patient's motivation and resolve natural ambivalence between the status quo and the effort needed to change. Therefore, A is the best answer. B is wrong because counseling is more than giving advice. C speaks to supporting the patient's autonomy, which is important, but not to making progress toward change. D is wrong because argument is specifically avoided in change counseling and is a sign of dysfunction in the patient-physician relationship. E is important for counseling, but it does not go far enough in defining the goals of change counseling.

2. Which of the following motivational interviewing skills are most useful in helping patients explore their ambivalence and talk themselves into changing?

A. Giving clear, simple explanations about medical conditions and the changes people can make to reduce the risks to their health
B. Using open questions and statements of affirmation and reflection to guess a patient's meaning and summarizing a patient's perspectives
C. Obtaining a complete assessment of risks, prior patient behaviors, and experiences with making other changes in their lives
D. Using the conviction-confidence ruler to assess the patient's reasons for changing and reasons for sustaining the status quo
E. Acknowledging nonverbal emotion caused by clinicians giving advice or telling patients what to do

Answer: B B is the correct answer because it states the four skills that characterize motivational and most patient-centered interviewing: open questions, affirmation, reflection, and summarization. Although a health risk assessment is an important starting point for change counseling, A is incorrect because it is limited to giving advice. C is incorrect because obtaining an assessment, although important, is only part of the task. D is incorrect because the purpose of the conviction-confidence ruler is to assess motivation, and D describes decisional ambivalence. Acknowledging emotions is an important engagement skill, but E is incorrect because the answer is limited to advice given by clinicians.

3. What is the purpose of a decisional balance tool in change counseling?

A. It shows the balance of risks of disease and benefits of treatment.
B. It documents the clinician's decisions for the changes patients need to make.
C. It tracks change in the patient's confidence during the course of counseling.
D. It demonstrates the patient's perceived importance of making a change.
E. It displays a patient's ambivalence between making change and sustaining the status quo.

Answer: E E is correct. The decisional balance is a counseling tool that displays a patient's ambivalence, showing the arguments for sustaining the status quo in one column and the arguments for change in an adjacent column. It is a potential starting point for change counseling in the precontemplation and contemplation stages. A is incorrect because the decisional balance is not about the clinician's decisions. B is not correct; although putting the decisional balance in the medical record documents its use and its results, decisional balance displays the patient's ambivalence, not the physician's decisions. C is wrong because the decisional balance displays ambivalence and does not track changes in commitment. D is partially correct because the decisional balance documents the patient's reasons for change, but it also documents the reasons for sustaining the status quo.

15

THE PERIODIC HEALTH EXAMINATION

DAVID ATKINS AND MARY BARTON

Primary and secondary prevention is an essential part of primary care and the patient-centered medical home (Chapter 13). The appropriate services and their frequency vary with the age, gender, and individual risk factors of each patient. A periodic health examination focusing on prevention increases the delivery of appropriate screening and lifestyle counseling. The most comprehensive prevention recommendations are produced by the U.S. Preventive Services Task Force (USPSTF), an ongoing panel of experts supported by the federal Agency for Healthcare Research and Quality (http://www.uspreventiveservicestaskforce.org).

USPSTF recommendations are used by major primary care subspecialty groups, many health plans, and quality organizations, and their A and B recommendations guide preventive services that are covered under the Affordable Care Act. The USPSTF bases its recommendations on two factors: an estimate of the *net benefits* (benefits minus harms) of a service, and an assessment of the *certainty* of that estimate, based on the rigor of supporting studies. Grade A recommendations require high certainty of a substantial net benefit, most often from large, prospective, controlled studies that measure morbidity or mortality. Grade B recommendations have high certainty of moderate net benefit or have moderate certainty for substantial benefit. USPSTF recommendations are thus more conservative than those of some subspecialty organizations that may give more weight to indirect evidence, such as earlier detection of disease, and less weight to potential harms of interventions. Clinicians can draw several general conclusions from an evidence-based approach to prevention: we should be selective in our use of screening tests, especially in older patients, and involve patients in decisions about specific services for which a small chance of benefit must be balanced against possible harm.

HISTORY AND RISK ASSESSMENT

The history and risk assessment are important tools to identify individuals who may need additional screening tests or immunizations not generally recommended for their age group or who may benefit from specific counseling to address unhealthy behaviors. Formal health risk appraisals should be linked to a system to provide specific feedback and targeted interventions.[1] Risk assessment should address the following:

- Use of tobacco, alcohol, and other drugs (especially injection drugs) (Chapters 32, 33, and 34)
- Diet (Chapters 213 and 220)
- Physical activity (Chapter 16)
- Sexual behavior that may increase the risk for sexually transmitted diseases or unintended pregnancy (Chapters 285, 384, and 387)
- Family history of cancer and heart disease
- Birthplace and current residence (community risk for infectious diseases)
- Presence of chronic diseases, such as diabetes, and of other cardiovascular risk factors

SCREENING FOR EARLY DISEASE OR ASYMPTOMATIC RISK FACTORS

Every year, new screening tests are introduced and marketed on the basis of their ability to detect unrecognized diseases or risk factors for disease. Other conditions need to be fulfilled for a screening test to be worthwhile for routine use, however (Table 15-1). Benefits of screening must be balanced against the potential harms, including false-positive results and the risks and costs of follow-up procedures or treatments. Even when tests have high specificity, the majority of positive results will be false-positive results if the test is used to screen healthy populations for uncommon conditions such as cancer (Chapter 10). There is growing evidence that cancer screening can lead to "overdiagnosis"—detection of slow-growing cancers that would never have caused clinical symptoms in a patient's lifetime.[2] Overdiagnosis subjects patients to the side effects of treatment with no benefits. A relatively small number of screening tests have been proved beneficial for the general population (Table 15-2), but additional tests are indicated for specific populations at risk (Table 15-3). Many commonly used tests are not recommended by the USPSTF (Table 15-4) because they provide little benefit or lack sufficient evidence to prove or disprove their value.

Depression

Depression is common and frequently undetected in primary care (Chapter 397). Simple screening instruments, including the following two questions—During the past 2 weeks, have you felt down, depressed, or hopeless? During the past 2 weeks, have you felt little interest or pleasure in doing things?—increase the detection of major depression. To improve outcomes, however, screening for depression must be linked to an organized system with staff support to ensure follow-up and treatment.[3]

High Blood Pressure, Abnormal Lipids, and Other Coronary Risk Factors

Overall cardiovascular risk, based on age, gender, blood pressure, lipid levels, and diabetes status, should be calculated at regular intervals to guide treatment decisions to reduce cardiovascular risk.[4] Blood pressure should be measured at least every 2 years (Chapter 67). The USPSTF recommends measuring total and high-density lipoprotein cholesterol, which can be done on fasting or nonfasting samples, beginning in middle age or earlier in the presence of other cardiovascular risk factors. Recommendations from the American Heart Association and American College of Cardiology favor fasting lipoprotein analysis, which will identify patients with severe LDL-C

TABLE 15-1 REQUIREMENTS OF AN EFFECTIVE SCREENING TEST

The disease being screened for is an important cause of morbidity and mortality.
Screening can detect disease in an early, presymptomatic phase.
Screening and treatment of patients with early disease or risk factors produce better health outcomes than does treatment of patients when they present with symptoms.
Screening test is acceptable to patients and clinicians—safe, convenient, acceptable false-positive rate, acceptable costs.
Benefits of early detection and treatment are sufficient to justify potential harms and costs of screening.

TABLE 15-2 PREVENTION RECOMMENDATIONS FOR THE GENERAL POPULATION: FROM THE U.S. PREVENTIVE SERVICES TASK FORCE AND OTHER SOURCES

SCREENING

Height, weight, and body mass index (BMI) calculation: periodically
Blood pressure: at least every 2 yr
Screen for alcohol misuse
Brief screen for depression*
Total blood cholesterol and HDL cholesterol: every 5 yr for men and women ≥20 yr with CHD risk factors and men ≥35 yr without CHD risk factors
Colorectal cancer screening: age ≥50 yr (see text for options)
Mammogram: at least every 2 yr for women ≥50 yr; discuss with women 40–49 yr
Papanicolaou (Pap) test: at least every 3 yr for sexually active women aged 21–29 yr; every 5 yr when combined with HPV testing in women 30-65 yr; in absence of HPV testing, continue every 3 yr until age 65
HIV test: at least once in all adults; repeat based on high-risk sexual activity
Chlamydia and gonorrhea: sexually active women ≤24 yr and older women at risk
Bone mineral density test: women ≥65 yr and high-risk women <65 yr

COUNSELING

Substance use
  Tobacco cessation
  Reduction of risky or harmful alcohol use
Diet and exercise
  Limit saturated fat; maintain calorie balance; emphasize grains, fruits, and vegetables‡
  Regular physical activity†
Sexual behavior
  Unintended pregnancy: contraception
  STD prevention: avoid high-risk behavior, use condoms or female barrier with spermicide†
Injury prevention
  Lap and shoulder belts
  Motorcycle, bicycle, and ATV helmets†
  Smoke detector†
Dental health
  Regular visits to dental care provider†
  Floss, brush with fluoride toothpaste daily†

IMMUNIZATIONS

Pneumococcal vaccine (once, age ≥65 yr)
Influenza vaccine (annual)
Tetanus-diphtheria (Td) boosters (every 10 yr)
Measles, mumps, rubella (MMR) vaccine (susceptible adults aged 19–49 yr)§
Varicella (two doses, susceptible adults aged 30–49 yr)§
Human papillomavirus (HPV) vaccine (three doses, women ≤26 yr)

CHEMOPREVENTION

Multivitamin with folic acid (women planning or capable of pregnancy)
Discuss benefits and harms of aspirin to prevent cardiovascular disease in middle-aged adults and others at increased risk for vascular disease

*Depression screening is most effective where systems exist to improve its management.
†The ability of clinician counseling to influence this behavior is uncertain.
‡Diet counseling is most effective when it targets at-risk groups (overweight or with CHD risk factors).
§Immunity can be verified by serologic testing, documented history of illness, or vaccination.
Other sources for Tables 15-2 and 15-3 include U.S. Department of Health and Human Services (diet, physical activity) and Centers for Disease Control and Prevention (injury prevention, immunizations, PPD).
ATV = all-terrain vehicle; CHD = coronary heart disease; HDL = high-density lipoprotein; STD = sexually transmitted disease.

TABLE 15-3 RECOMMENDED SCREENING AND INTERVENTIONS FOR HIGH-RISK POPULATIONS

POTENTIAL INTERVENTION	POPULATION
Ultrasound examination for abdominal aortic aneurysm	Current or former male smokers aged 65-75 yr
Low-dose computed tomography for lung cancer	Smokers with at least 30 pack-year smoking history (current smokers and those who quit smoking within past 15 years)
Hepatitis C test	Born 1945 to 1965; history of injection drug use or other high risk behaviors
Syphilis (RPR/VDRL)	High-risk sexual behavior; consider local epidemiology*
Gonorrhea screen	High-risk sexual behavior; consider local epidemiology*
PPD	Specific immigrant groups, prisoners, HIV patients
Hepatitis B vaccine	Exposure to blood products; IV drug use; high-risk sexual behavior; travelers to high-risk areas
Hepatitis A vaccine	Persons living in or traveling to high-risk areas; institutionalized persons and workers in these institutions; those with certain chronic medical conditions
Meningococcal vaccine	First-year college students in dormitories; military recruits; those with asplenia; travelers to high-risk areas
Varicella vaccine	Adults born after 1980 without evidence of immunity
Breast cancer chemoprevention	Women at increased risk for breast cancer and with low risk for thromboembolic complications
Diabetes screen	Persons at increased risk of diabetes

*Routine screening may be indicated in communities or settings where infection is prevalent.
HIV = human immunodeficiency virus; IV = intravenous; PPD = purified protein derivative; RPR = rapid plasma reagin; VDRL = Venereal Disease Research Laboratory.

TABLE 15-4 INTERVENTIONS NOT RECOMMENDED FOR ROUTINE USE IN ASYMPTOMATIC AVERAGE-RISK ADULTS*

Resting or exercise electrocardiography (D) or helical computed tomography (CT) for asymptomatic coronary disease (I)
Ultrasound examination for asymptomatic carotid artery stenosis (D)
Chest radiograph for lung cancer
Oral examination for oral cancer (I)
Routine blood tests for anemia
Routine urine tests (to screen for infection, cancer, or chronic kidney disease) (I)
Blood tests or ultrasound examination for ovarian cancer (D)
Whole body CT
Brief tests of mental status to detect dementia (I)
Vitamin supplements (I, D)
Blood level of C-reactive protein to predict coronary risk (I)
Prostate-specific antigen for prostate cancer (D)

*These services have either insufficient evidence to support routine use (I) or at least fair evidence that they provide no benefit or that harms outweigh benefits (D).

elevations (>190 mg/dL) (Chapter 206). Either strategy is sufficient to calculate a 10-year cardiovascular risk and to identify patients who may benefit from statin therapy (Chapter 52), which should be considered whenever the 10-year risk exceeds 7.5%. Although factors such as C-reactive protein, homocysteine, and coronary calcification as assessed by computed tomography (CT) are associated with an increased risk for heart disease, the USPSTF found insufficient evidence to recommend their routine use.

Abdominal Aortic Aneurysm

Between 5 and 9% of men older than 65 years have an abdominal aortic aneurysm (Chapter 78). The risk for aneurysm is highest in smokers and is substantially lower in women (1%). The USPSTF recommends one-time screening with ultrasound examination in men aged 65 to 75 years who are

current or former smokers,[5] based on trials demonstrating as much as a 40% lower death rate from abdominal aortic aneurysm rupture in screened men.

Colorectal Cancer

Screening can reduce both the incidence of and mortality from colorectal cancer. Options for screening men and women older than 50 years include an annual highly sensitive fecal occult blood test (FOBT) or fecal immunochemical test, flexible sigmoidoscopy every 5 years plus FOBT every 3 years, or colonoscopy every 10 years (Chapter 193). Colonoscopy combines detection with the opportunity for biopsy and removal of lesions, so it is preferred in some guidelines. It carries higher costs and risks, however, and no single strategy has proved to be more effective or cost-effective than the alternatives. In a randomized trial, a single flexible sigmoidoscopy screening between 55 and 64 years of age reduced the colorectal cancer incidence by 33% and the colorectal cancer mortality by 43% after 11 years of follow-up in people who were screened.[6] In 2008, the USPSTF concluded that evidence was not yet sufficient to support newer technologies such as CT colonography or fecal tests for DNA markers of neoplasia. DNA tests were approved by FDA in 2014 and are more sensitive but less specific than FOBT.[7] The USPSTF recommends stopping routine screening at age 75 years.

Breast Cancer

In large trials, mammography screening (at intervals of 1 to 2 years, with or without clinical breast examination) reduces breast cancer mortality by 15 to 30% (Chapter 198). Most trials suggest that the benefits of screening extend to women in their 40s, but the benefits are smaller and the risks for false-positive results are higher than in women aged 50 to 70 years.[8] If a woman aged 40 to 49 years has a two-fold increased risk for breast cancer, she will have a similar benefit-to-harm ratio for biennial screening mammography as an average-risk woman aged 50 to 74 years.[9] No studies provide data on the benefits of screening women aged 75 and older. In a collaborative study, six independent models predicted that an average of 80% of the benefit of mammography could be achieved with biennial rather than annual mammography, whereas national mammography surveillance data indicate that false-positive results and other harms of screening would be reduced by about half if women were screened every other year instead of yearly. Although many cancers are discovered by patients, teaching women to perform breast self-examination increases the likelihood that a woman will undergo further evaluation for an unimportant finding, but it does not improve outcomes. Widespread screening for *BRCA1* or *BRCA2,* inherited mutations that increase the risk for breast cancer, is not recommended, but the USPSTF recommends that primary care providers screen women who have family members with breast, ovarian, tubal, or peritoneal cancer using one of several recommended family history screening tools designed to identify women at risk for potentially harmful mutations. Women with a positive family history should be referred for genetic counseling.[10]

Cervical Cancer

Papanicolaou (Pap) screening is highly effective in preventing invasive cervical cancer, but many low-risk women in the United States are screened more often than needed. The USPSTF and a multi-specialty-society collaborative[11] endorse delaying screening until age 21 and then screening women aged 21 to 30 years with previous normal test results only every 3 years instead of annually (Chapter 199). In women ages 30 to 65 years, both groups recommend adding testing for the human papillomavirus (Chapters 18 and 373) to Pap testing (co-testing) and extending the interval between screens to 5 years. Women with adequate screening histories should be given the option of discontinuing screening after 65 years of age. Screening is not indicated in women who have undergone a hysterectomy for benign disease. Whether women who have received the human papillomavirus vaccine (Chapter 18) need less frequent screening is not yet known.

Prostate Cancer

Screening with prostate-specific antigen (PSA) can increase the detection of organ-confined prostate cancer, but two large trials provided conflicting results as to whether screening lowers morbidity or mortality from prostate cancer (Chapter 201). An American trial found no benefit of annual PSA testing, but it was hampered by a high rate of screening in the control group. A European study reported that men randomized to screening every 4 years had a 20% lower risk of dying from prostate cancer after 9 years; for each prostate cancer death prevented, 48 additional men were treated for prostate cancer, and 1068 men had to undergo screening. Because of the small benefit and significant morbidity associated with overdiagnosis and overtreatment, including incontinence and impotence, the USPSTF recommends against routine PSA screening,[12] but the American College of Physicians and some specialty groups recommend discussing PSA screening with men who have a life expectancy of at least 15 years.

Lung Cancer

The USPSTF now recommends annual screening with low-dose CT in adults aged 55 to 80 years who have at least a 30 pack-year smoking history and currently smoke or have quit within the last 15 years, based on a large trial in which such screening reduced deaths from lung cancer by 20% and all-cause mortality by 7%.[13] More than 10% of screened persons will have another clinically significant finding, such as a mass in the kidney or adrenal gland or an aortic aneurysm, and at least one false-positive test will occur in more than 40% of screened adults.

Osteoporosis

Tests of bone mineral density can identify men and women with a high risk for fracture due to osteoporosis and who may benefit from medications proved to lower the risk for fracture (Chapter 243). The USPSTF recommends screening for osteoporosis in women older than 65 years as well as in younger women who have risk factors that put them at comparable risk.[14] The most accurate predictor of risk for hip fracture is bone mineral density of the hip assessed with dual-energy x-ray absorptiometry. A tool developed by the World Health Organization (http://www.shef.ac.uk/FRAX/) incorporates bone mineral density and other risk factors, such as age and fracture history, to guide treatment decisions.

Thyroid Disease

Routine thyroid testing occasionally identifies patients with symptomatic but undiagnosed hypothyroidism (Chapter 226), but it more often detects subclinical hypothyroidism, a disorder marked by elevations in thyroid-stimulating hormone with normal levels of free thyroxine. Because the benefits of treating subclinical hypothyroidism remain uncertain, the USPSTF does not recommend routine thyroid testing in the absence of symptoms. Clinicians should be alert to subtle signs of thyroid disease and have a low threshold for testing patients in high-risk groups, including postpartum and postmenopausal women.

Diabetes

Routine screening for diabetes beginning at age 45 years is recommended by some groups, but the USPSTF recommends screening for abnormal blood glucose and type 2 diabetes only in patients at increased risk based on age, overweight, or family history. Although tight glucose control can reduce the incidence of microvascular disease, the benefit of early presymptomatic detection on clinically important retinopathy, neuropathy, and nephropathy is likely to be small. The benefits of early detection of diabetes are based primarily on the benefits of intensive lifestyle modifications.

HIV Infection

The USPSTF and Centers for Disease Control and Prevention (CDC) recommend screening for HIV infection (Chapters 387, 388, and 389) in all adolescents and adults aged 15 to 65 years, including pregnant women. Whether to continue screening after age 65 years should consider risk factors such as new sexual partners. The optimal screening interval is unclear, but annual screening is reasonable in persons at very high risk, such as individuals who are actively engaged in risky sexual behaviors. Rescreening is not necessary in seronegative patients who have not been at increased risk since the last screen.

Hepatitis C Infection

Drugs for chronic hepatitis B and C infection (Chapter 149) have increased the ability to achieve viral suppression and prevent the complications of chronic liver disease in infected individuals. As a result, the USPSTF and CDC now recommend screening for hepatitis B and C in persons at high risk for infection, especially individuals with a history of past or current injection drug use.[15,16] Because persons born between 1945 and 1965 account for three fourths of Americans living with hepatitis C, one-time screening in this cohort is also recommended.

Sexually Transmitted Disease

Screening for chlamydia (Chapter 318) is recommended for all sexually active women aged 24 years and younger and for older women at risk. Nucleic acid amplification tests can be performed on cervical or urine

specimens. Early detection can reduce pelvic inflammatory disease (Chapter 285), a risk factor for infertility and ectopic pregnancy. Similar benefits are likely from screening women for gonorrhea (Chapter 299), but the risk for gonorrhea infection is more concentrated in high-risk urban and southeastern rural populations.

Vision and Hearing

Undetected but correctable vision (Chapter 423) and hearing (Chapter 428) problems are common in older adults and can be discovered by asking about problems and performing simple tests of visual acuity and hearing. Unfortunately, evidence is limited to show that regular screening leads to measureable benefits in function. Regular visual acuity testing is recommended for older adults by many organizations, but a large trial did not find any lasting benefits of screening, despite detecting many correctable causes of vision problems. The USPSTF concluded that evidence was insufficient to recommend routine vision or hearing screening.

BEHAVIORAL INTERVENTIONS

Lifestyle factors contribute to a large proportion of preventable deaths in the United States. Brief interventions are effective for some behaviors such as smoking and problem drinking, but changing other behaviors usually requires more intensive approaches. The *5 As* framework—ask, assess, advise, assist, and arrange—which was developed from smoking cessation research, provides a useful framework for counseling (Chapter 14).

Tobacco Use

Brief interventions can produce small but clinically important increases in quit rates among smokers. Effects increase with more intensive counseling and support, including the use of medication (Chapter 33).

Alcohol Misuse

The USPSTF recommends screening all adults 18 years or older for alcohol misuse with one of three tools: the 10-question AUDIT instrument, its 3-question version AUDIT-C (http://www.integration.samhsa.gov/images/res/tool_auditc.pdf), or a single question: "How many times in the past year have you had five (for men) or four (for women and adults over 65 years old) or more drinks in a day?"[17] Brief multi-contact behavioral interventions can successfully reduce alcohol consumption in at-risk drinkers (Chapter 33).

Diet

Diet counseling can reduce the intake of saturated fat and increase the consumption of fruits and vegetables. Effects are most consistent with more intensive counseling (multiple sessions with trained counselors) and in higher risk patients, such as those with elevated lipid levels (Chapter 213).

Physical Activity

Moderate physical activity reduces the risk for obesity, diabetes, and coronary heart disease, among other benefits. Studies of counseling in the primary care setting, however, have reported inconsistent effects on long-term levels of physical activity (Chapter 16).

Injury Prevention

Motor vehicle injuries are the leading cause of years of potential life lost before age 65 years. In older persons, falls are a leading cause of unintentional injury and can be reduced with targeted interventions (Chapter 25). The USPSTF recommends targeted interventions for at-risk persons, such as exercise, physical therapy, and vitamin D supplementation (Chapter 25).[18] The USPSTF recommends that women of childbearing age be screened for intimate partner violence (Chapter 241)[19] but found insufficient evidence to recommend screening all elderly or other vulnerable adults for abuse and neglect.

IMMUNIZATIONS

Recommendations regarding immunization (Chapter 18) are regularly updated by the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention (http://www.cdc.gov/vaccines).[20] Annual influenza immunization is recommended for all adults. Vaccination with pneumococcal polysaccharide (PPSV23) is recommended at least once at age 65 years or after for all adults and for younger adults with asplenia, chronic heart or lung disease, and other immune disorders. Revaccination is not generally recommended unless the initial immunization was before age 65 years or the patient has immune-related risk factors. Adults with immunocompromising conditions, including chronic renal failure, should also receive pneumococcal conjugate 13-valent vaccination (PCV13). Two doses of varicella vaccine are recommended for all adults born in the United States after 1980 without other evidence of immunity, and one dose of zoster vaccine is recommended for all adults at age 60 years. Adults should be revaccinated once with the Tdap vaccine (tetanus, diphtheria, acellular pertussis) and every 10 years with Td; if their vaccination history is uncertain, complete primary immunization with two additional doses of Td is recommended. A series of three doses of a vaccine against human papilloma virus (HPV) is recommended for young women up to age 26 years (with HPV4 or HPV2) to reduce the risk for cervical cancer and for men up to age 21 years (with HPV4) to reduce the risk for genital warts and the transmission of the virus.

CHEMOPREVENTION AND SUPPLEMENTS

Aspirin, postmenopausal hormone replacement therapy, breast cancer chemopreventive drugs, and supplements of vitamins or minerals can carry both benefits and risks. Decisions need to consider the likely benefits (which increase with the underlying risk of the disease being prevented), the probability of harm, and the individual preferences of each patient.

Aspirin

In men and women without known vascular disease, aspirin reduces the combined risk for myocardial infarction, stroke, and other serious cardiovascular events by 12%, but it also increases the risk for serious gastrointestinal bleeding and hemorrhagic stroke and does not significantly reduce cardiovascular mortality. For men ages 45 to 79 years and women ages 55 to 79 years, clinicians should assess whether the benefits, which increase with higher risk for vascular disease, outweigh the bleeding risks, which increase with age (Chapter 38).

Chemoprevention of Breast Cancer

Tamoxifen and raloxifene can reduce the incidence of invasive breast cancer by nearly 50% in women at increased risk, but both agents increase the risk for thromboembolic events and worsen menopausal symptoms; tamoxifen also increases the risk for endometrial cancer (Chapter 198). The USPSTF recommends clinicians discuss the balance of benefits and harms of these medications with women over age 35 years who are at increased risk for breast cancer. Women most likely to benefit are those who are younger than age 60 years and whose 5-year risk of invasive breast cancer is 3% or higher.[21] Online tools can be used to assess this risk (http://www.cancer.gov/bcrisktool/).

Postmenopausal Hormone Therapy

In long-term follow-up studies, estrogen-only therapy reduced the risk for fracture and invasive breast cancer but increased the risk for stroke, thromboembolism, gallbladder disease, and incontinence (Chapter 240). Combination therapy with estrogen and progestin generally has comparable benefits and risks, but it increases the risk for invasive breast cancer and also increases the risk for dementia.[22] Hormone therapy is a reasonable option for younger menopausal women with persistent, troublesome menopausal symptoms, but the USPSTF recommends against its routine use for preventive purposes.

Vitamin and Mineral Supplementation

The USPSTF does not recommend routine use of vitamin or mineral supplements because there is no convincing evidence that multivitamins or individual or paired supplements (e.g., vitamin A, C, D, or E; folic acid; beta-carotene; selenium; or calcium) reduce cardiovascular disease, cancer, or all-cause mortality in community-dwelling average-risk adults.[23] The USPSTF found insufficient evidence to support routine use of calcium and vitamin D supplements for the primary prevention of fractures in ambulatory adults, but primary prevention studies most commonly targeted healthy postmenopausal women. Vitamin D supplementation is recommended for individuals older than 65 years who are at risk for falls (see Injury Prevention), although the mechanism of action is uncertain.

FUTURE ISSUES

There is growing awareness that many older patients receive cancer screening well beyond the ages at which they are likely to benefit. Making clear recommendations for older patients is complicated by lack of good evidence, the difficulty assessing life expectancy, and differences in patients' preferences.[24] As the understanding of genetic factors that modify the risk for disease grows, clinicians may eventually be able to target screening, preventive treatments,

or lifestyle interventions to those at greatest risk. The value of using currently available genomic tests to screen average-risk individuals is limited by an incomplete understanding of the predictive value of specific genotypes in the general population, the uncertain effect of such information on clinical decisions, and concerns about the possible adverse effects of screening (e.g., anxiety or "labeling," false reassurance, discrimination).

REVIEW QUESTIONS

1. A 40-year-old married woman comes for her periodic health examination. She has had negative annual Pap tests for the last 5 years. Which of the following options describes a recommended strategy for cervical cancer screening?

A. Obtain a human papillomavirus (HPV) test along with the Pap test; if both are normal, no screening will be needed for 5 years.
B. Because her last Pap was normal, defer Pap testing until next annual examination.
C. Continue annual screening until the age of 64 years.
D. Continue annual screening until age 50 years.
E. Begin annual HPV testing but lengthen the interval for Pap testing to every 5 years.

Answer: A In the absence of HPV testing, every-3-year Pap testing is recommended by the U.S. Preventive Services Task Force (USPSTF) and the American College of Obstetrics and Gynecology (ACOG) for women with previously normal Pap tests. In women who are HPV negative, the interval can safely be extended to every 5 years. Co-testing (combined Pap and HPV testing) at 5-year intervals is recommended by the USPSTF and ACOG beginning at the age of 30 years and extending to age 65 years.

2. A 52-year-old woman is new to your practice. She is a lifelong nonsmoker, and she had her first mammogram in the past year, with normal results. She has never undergone colorectal cancer screening. Which of the following is true regarding recommendations for screening and options available to her?

A. As an average-risk adult, she could be offered screening with any of the following options, which differ in their risks, intervals, and burdens of testing: high-sensitivity fecal occult blood testing (FOBT), flexible sigmoidoscopy with FOBT, or colonoscopy.
B. Regular colorectal cancer screening in adults should stop at age 65 years.
C. Computed tomography (CT) colonography at 10-year intervals is an acceptable option in place of colonoscopy.
D. Colonoscopy every 5 years is the preferred option because of its higher sensitivity.
E. Flexible sigmoidoscopy at 5-year intervals should be combined with annual FOBT.

Answer: A The U.S. Preventive Services Task Force (USPSTF) recommendations are based on a review of original studies and a commissioned comparative model to determine optimal age for starting and stopping screening for colorectal cancer and the optimal intervals. USPSTF recommendations suggest beginning screening at age 50 years and stopping regular screening at age 75 years. Their analyses indicated that either (1) annual high-sensitivity fecal occult blood testing (FOBT), (2) flexible sigmoidoscopy every 5 years combined with FOBT every 3 years, or (3) colonoscopy every 10 years would yield similar benefits over a population. CT colonography every 5 years and double-contrast barium enema every 5 years are included options in the 2008 guidelines of the Multisociety Task Force because of their ability to detect both cancer and polyps.

3. A 62-year-old African American man comes in for his first visit. Other than a 5-year history of high blood pressure, he is in good health. In response to questions about whether he should get a prostate-specific antigen (PSA) test, which of the following statements reflects information that should be part of a shared decision-making discussion?

A. As an African American, he has a higher risk for prostate cancer but may not benefit more from screening compared with men of other ethnic backgrounds.
B. PSA screening has been shown to reduce mortality from prostate cancer in some studies.
C. False-positive PSA tests are common and may require a biopsy.
D. PSA testing may result in detection and treatment of a cancer that would not have caused clinical problems (overdiagnosis).
E. All of the above

Answer: E Although African American men do have an increased risk for prostate cancer, there is no evidence that benefits of screening are any higher in this group. PSA testing was associated with lower prostate cancer mortality in one European study, in which 48 men needed to be treated for every 1 death prevented after 9 years. By comparison, mortality was not significantly lower in a large American trial. False-positive PSA results and potential overdiagnosis are the major concerns regarding prostate cancer screening. As a result, none of the major organizations recommends routine screening with PSA, although some recommend a shared decision-making approach (http://www.auanet.org/education/guidelines/prostate-cancer-detection.cfm).

4. A 58-year-old male accountant comes in for a periodic examination. He is recently divorced and has a steady female partner with whom he is sexually active. Because his partner is postmenopausal, they do not use condoms. He has never been screened for any sexually transmitted diseases and has no symptoms nor history of any drug use or transfusions. Which of the following tests are indicated as a screening test?

A. HIV
B. Hepatitis C
C. Chlamydia
D. Gonorrhea
E. Hepatitis B

Answer: A and B HIV testing is indicated in all adults who have never been screened. Although the subject has no specific risk factors for hepatitis C, testing is recommended for adults in his age cohort (born between 1945 and 1965). Chlamydia and gonorrhea screening might be indicated for a woman based on having a new sexual partner but is not recommended for men. Hepatitis B screening is recommended only for high-risk groups in nonpregnant adults.

5. A 40-year-old nonsmoking man is seen for his periodic examination. He has a healthy weight (body mass index = 20), blood pressure of 118/78 mm Hg, and no history of diabetes, and he is able to exercise regularly without symptoms. Last year, his nonfasting total cholesterol was 232 with an HDL of 50. Which of the following represents appropriate steps to address cardiovascular prevention in this patient?

A. Perform a baseline electrocardiogram to look for evidence of ischemia or ventricular hypertrophy.
B. Obtain a fasting lipoprotein analysis.
C. Recommend he begin a daily low-dose aspirin regimen.
D. Calculate his 10-year risk for cardiovascular disease to assess need to consider further interventions.
E. Obtain a coronary computed tomography (CT) to look for evidence of calcifications

Answer: D Ten-year cardiovascular risk can be calculated using age, gender, lipids, blood pressure, and history of diabetes and smoking. This patient's 10-year risk is only 1.3%, putting him in a low-risk category; any benefits of aspirin will be offset by risks for gastrointestinal bleeding. Fasting lipoprotein analysis, although it will allow you to assess triglyceride and LDL cholesterol, is not needed because risk calculators require only total cholesterol and HDL. Neither ECG nor coronary CT is recommended by the U.S. Preventive Services Task Force as screening tests for coronary disease. Because findings on coronary CT are associated with risk for coronary events, some organizations suggest this test can be considered in patients who are near a threshold for considering statin therapy (7.5% 10-year risk for cardiovascular disease).

PHYSICAL ACTIVITY

DAVID M. BUCHNER

DEFINITIONS

Physical activity can be broadly defined as body movement that is produced by skeletal muscles and expends energy. *Health-enhancing physical activity* is activity that, when added to light-intensity activities of daily life, produces health benefits and involves the large muscle groups of the body and substantial energy expenditure. Herein, *physical activity* refers to health-enhancing physical activity. *Exercise* refers to the subset of physical activity that involves a structured program to improve physical fitness.

Regular physical activity improves *health-related physical fitness*—the physiologic components of fitness that influence risk for disease, functional limitations, disability, and premature mortality. These components include cardiorespiratory endurance (aerobic capacity); skeletal muscle strength, power, and endurance; body composition and bone strength; and balance, flexibility, and reaction time.

The primary attributes of physical activity are *type* (mode), *frequency, duration,* and *intensity.* Types of physical activity (e.g., walking, swimming, lifting, stretching) are grouped according to their main physiologic effects into well-known categories: *aerobic* (or "cardio"), *muscle strengthening, flexibility,* and *balance.* Intensity is the level of effort during activity. For aerobic activity, the *absolute intensity* is measured in metabolic equivalents (METs), with 1 MET being the resting metabolic rate—an oxygen consumption of roughly 3.5 mL/kg/minute. *Absolute* intensity is commonly classified into: sedentary behavior (1.0 to 1.5 MET), light intensity (1.6 to 2.9 MET), moderate intensity (3.0 to 5.9 MET), and vigorous intensity (6.0 MET and higher). The *relative intensity,* which is the percentage of oxygen uptake (aerobic capacity) reserve required to perform an activity, ranges from 0 to 100%. In practice, the heart rate is used to monitor relative intensity because of the generally linear relationship between heart rate and percentage of oxygen uptake.

The *volume* (or amount) of activity is the product of frequency, duration, and intensity. Volume can be measured using self-report (questionnaires) as MET-minutes per week (a sum of the MET intensity of all activities multiplied by the minutes each activity is performed). Volume can also be assessed using objective measures of physical activity in either arbitrary units ("counts per day" from an accelerometer) or as activity-related energy expenditure (kcal/week). A commonly used objective measure is the accelerometer (usually worn at hip or wrist, for 1 week), which detects movement of the body and provides detailed information on the frequency, duration, and intensity of movement.

EPIDEMIOLOGY

Levels of Physical Activity

It is highly likely that Americans' total level of physical activity has declined since the 1950s. Occupational activity has probably declined the most, but activity around the home and as transportation for getting places has also declined. Trends in recreational physical activity are either stable or slightly improving.

Based on self-reported activity, about 60% of adults meet public health guidelines for physical activity,[1] but only about 10% to at most 45% of American adults meet these guidelines based on accelerometer data collected at the same time. Although one accelerometer reading is not a perfect measure of average physical activity levels, the magnitude of this discrepancy suggests that adults commonly over-report their activity levels and that physical inactivity is a larger public health problem than previously realized.

Physical activity levels decline with age, and men report more activity than women. Higher levels of income and education are associated with greater physical activity. Although white Americans self-report higher levels of physical activity than do other racial and ethnic groups, Mexican American adults are the most active group as judged by accelerometer data.[1]

Preventive Health Benefits in Adults

There is strong evidence that regular moderate or vigorous physical activity (Table 16-1) reduces the risk for premature mortality and coronary artery disease (Chapter 52), stroke (Chapter 406), high blood pressure (Chapter 67), adverse lipid profile (Chapter 206), type 2 diabetes mellitus (Chapter 229), metabolic syndrome, osteoporosis (Chapter 243), colon cancer (Chapter 193), breast cancer (Chapter 198), and obesity (Chapter 220).[2] Even 15 minutes per day or 90 minutes per week of moderately intensive exercise is associated with a 14% decrease in mortality.[3] Physical activity also reduces the risk for falls, cognitive impairment in older adults, age-related muscle loss, and depression (Chapters 25 and 397). There is moderate evidence that physical activity reduces the risk for hip fracture, lung cancer, endometrial cancer, and sleep disorders. Physical activity can delay age-related functional limitations and loss of independence. Some evidence also suggests that physical activity reduces the risk for anxiety disorders, osteoarthritis, and back pain.

The benefits of physical activity are independent of other risk factors. For example, a sedentary obese smoker achieves health benefits from exercise, even if smoking and obesity persist.

Epidemiologic studies report that low levels of activity are associated with an increased risk for adverse health outcomes,[4] including up to a 67% increase in overall mortality, a doubling of mortality from cardiovascular disease,[5] and an increased mortality from cancer. When a healthy diet, regular activity, and abstinence from smoking are considered simultaneously, the effect of lifestyle is even more dramatic.

The main determinant of the health benefits of physical activity is volume. Substantial health benefits begin to occur with a volume of 500 to 1000 MET-minutes/week. An adult can accumulate 500 MET-minutes by walking at 3.0 miles per hour (a 3.3-MET activity) on 3 days a week for 50 minutes (3.3 METs $\times$ 3 $\times$ 50 minutes $=\approx$500 MET-minutes). When measured by caloric expenditure, this volume of walking in a 75-kg (165-lb) adult expends an extra 430 kcal above the 190 kcal that would have been expended under resting conditions.

The dose-response relationship between volume and health benefits is curvilinear, such that the marginal benefit of activity at lower levels is large, and the benefit decreases with higher activity levels.[5] Data from the Women's Health Initiative Observational Study (Table 16-2) provide an example of the dose-response effect. Compared with the least active women, the risk for cardiovascular disease was 19% less in women who averaged 600 MET-minutes/week, yet just 28% less in women who averaged 1968 MET-minutes/week. Dose-response effects are also found in intervention studies. For example, a randomized trial of two doses of exercise (doses equivalent to jogging 12 and 20 miles/week) found that the lower volume of exercise significantly improved plasma lipoproteins, but the higher volume had greater beneficial effects.

TABLE 16-1 EXAMPLES OF MODERATE-INTENSITY AND VIGOROUS-INTENSITY ACTIVITIES

MODERATE INTENSITY
Walking briskly (3 miles per hour or faster, but not race-walking)
Water aerobics
Bicycling slower than 10 miles per hour
Tennis (doubles)
Ballroom dancing
General gardening
VIGOROUS INTENSITY
Race-walking, jogging, or running
Swimming laps
Tennis (singles)
Bicycling 10 miles per hour or faster
Jumping rope
Heavy gardening (continuous digging or hoeing, with heart rate increases)
Hiking uphill or with a heavy backpack

TABLE 16-2 RELATIVE RISK FOR CARDIOVASCULAR DISEASE IN THE WOMEN'S HEALTH INITIATIVE OBSERVATIONAL STUDY ($N = 73,743$)

MEDIAN MET-MINUTES PER WEEK	MULTIVARIATE ADJUSTED RELATIVE RISK FOR CARDIOVASCULAR DISEASE
0	1.0
252	0.89
600	0.81
1050	0.78
1968	0.72

Data from Manson JE, Greenland P, LaCroix AZ, et al. Walking compared with vigorous exercise for the prevention of cardiovascular events in women. *N Engl J Med.* 2002;347:716-725.

TREATMENT

Therapeutic Health Benefits in Adults

Clinical practice guidelines assign a substantial therapeutic role to physical activity in patients with coronary heart disease (Chapter 52), high blood pressure (Chapter 67), type 2 diabetes (Chapter 229), obesity (Chapter 220), osteoporosis (Chapter 243), osteoarthritis (Chapter 262), claudication (Chapter 79), and chronic obstructive pulmonary disease (Chapter 88).

In individuals with impaired glucose tolerance and high cardiovascular risk, both baseline activity levels and changes in activity levels are associated with a reduction in subsequent cardiovascular events.[6] Physical activity also plays a role in the management of depression and anxiety disorders, elevated cholesterol levels, pain, heart failure, syncope, stroke, back pain, dementia, and constipation and in the prophylaxis of venous thromboembolism.

Although there is more evidence for the therapeutic effects of aerobic activity, muscle-strengthening exercise can also provide benefits. For example, a randomized trial of exercise in adults with diabetes reported that the combination of aerobic and muscle-strengthening exercise was superior to either by itself.

Physical activity effectively opposes age-related loss of fitness and functional limitations. In older adults, low fitness (exercise capacity of <85% of predicted value) is associated with doubled risk for mortality. Randomized controlled trials demonstrate that exercise by sedentary older adults improves health-related physical fitness (e.g., aerobic exercise improves aerobic capacity) and has beneficial effects on functional limitations, such as a slow gait speed. A systematic review of nine observational studies reported that slow gait speed is strongly related to mortality as well, with low-risk adults having gait speeds of 1.0 meter/second or higher.[7] Physical activity, especially balance training, prevents falls in older adults at increased risk for falling, such as those with impaired gait and balance. Because both low fitness and high body weight cause functional limitations, the question arises whether functional ability is best improved by weight loss, exercise, or both. With the doses of weight loss and exercise that are feasible in randomized trials, exercise alone appears more effective than weight loss alone, and combined exercise and weight loss is most effective.

Health Risks of Physical Activity

Physical activity and exercise have risks. Musculoskeletal injuries are by far the most common type of activity-related adverse event. The risk for injury depends on the type and volume of activity. Collision and contact sports have a much higher injury risk than noncontact activities such as walking, which is associated with about one musculoskeletal injury for every 1000 hours of walking for exercise.[8] The weekly volume of activity is directly related to the risk for musculoskeletal injuries, but when following public health guidelines, which involves participating in about 500 to 1000 MET-minutes/week, the risk for injury is low. The risk for injury is directly related to the rate of increase in the dose of activity, with more rapid increases having higher risk.[2] Previous musculoskeletal injuries and low fitness also increase the injury risk.

Overall, regular physical activity decreases the risk for sudden cardiac death and myocardial infarction; active adults have roughly a 70% lower risk for sudden death. However, relatively vigorous physical activity acutely increases the risk for these events in both active and inactive adults. About 5 to 10% of myocardial infarctions are associated with vigorous activity. Yet sudden death is a rare event during exercise, with published rates in the range of one death per year in 18,000 ostensibly healthy men and one death per 2.6 million workouts in fitness facilities.

Physical Activity Guidelines for Adults

In 2008, the U.S. Department of Health and Human Services issued the first national physical activity guidelines: the *2008 Physical Activity Guidelines for Americans*[2] (Table 16-3).

Recommended Amounts of Aerobic Activity for Prevention

To obtain substantial health benefits from physical activity, adults should do at least 150 minutes/week of moderate-intensity aerobic activity or 75 minutes/week of vigorous-intensity activity. Adults can do a combination of both moderate- and vigorous-intensity activity, using the rule of thumb that one vigorous-intensity minute of activity counts the same as two moderate-intensity minutes. Bouts of aerobic activity 10 or more minutes clearly have health benefits, and even short bouts of less than 10 minutes may also provide some health benefits.[9]

Recommended Amounts of Muscle-Strengthening Activity for Prevention

Adults should perform activities that strengthen the major muscle groups of the body at least 2 days each week. The major muscle groups are the legs, hips, back, chest, abdomen, shoulders, and arms.

Flexibility Activity

Flexibility activities are an acceptable part of a physical activity regimen, but there is insufficient evidence that flexibility activities have any health benefits, even for preventing injuries. Flexibility training does increase flexibility, and it may facilitate the types of physical activity that do have health benefits. If so, flexibility training is more important for people with reduced flexibility, such as older adults with age- and disease-related changes in range of motion.

Balance Activity

Balance training is currently recommended only for adults at increased risk for falls (Chapter 24), such as those older than 65 years with impaired gait or balance or frequent falls. Examples of balance exercises include sideways walking, backward walking, heel walking, and standing using a narrow base of support. Tai chi programs include exercises that improve balance, and tai chi exercise is an evidence-based approach to fall prevention. Preferably, adults at risk for falls should do balance training at least 3 days/week and follow an evidence-based program demonstrated to reduce the risk for falls.

Sedentary Behavior

Sedentary behavior can be defined as activities (not including sleeping) with energy expenditure of 1.0 to 1.5 METs; most of these behaviors involve sitting or lying down. Epidemiologic studies report that higher levels of sedentary time (or equivalently lower levels of light-intensity activity) have adverse health effects, independent of a person's volume of moderate- to vigorous-intensity activity. More sedentary time as assessed by accelerometers is associated with greater body weight, worse markers of metabolic health, and higher mortality. Currently, light-intensity activities expend calories and can be recommended as part of a plan to achieve and maintain a healthy weight. However, data are insufficient to issue guidelines on the amounts and patterns of sitting time that cause adverse health effects in adults.

Guidelines for Weight Management

The amount of activity required to maintain a healthy body weight varies widely among adults (Chapter 220). For some adults, the physical activity levels recommended in the guidelines will result in a stable, healthy body weight. Many adults, however, need higher levels of activity to achieve a healthy weight. These individuals should restrict their caloric intake and gradually increase their physical activity each week, to the point that is effective in achieving and maintaining a healthy body weight for them.

Additional Guidelines for Older Adults

In addition to balance training, the 2008 guidelines contain other recommendations specifically for older adults. Older adults who cannot do 150 minutes/week of moderate-intensity activity should be as active as their abilities and conditions allow. Progressive resistance strength training improves physical function in elderly people.[A] Older adults should determine their level of physical activity using relative intensity, not absolute, intensity. This latter guideline seeks to avoid inappropriately high levels of effort in older adults with low fitness.

Recommending Physical Activity in Clinical Settings

Promoting physical activity in clinical settings involves essentially the same steps as the "5 As" of smoking cessation: ask, advise, assess, assist, arrange. (1) Ask about the amount of physical activity a patient typically engages in each week by questionnaire or interview. (2) Advise all patients to participate in at least a moderate amount of physical activity each week. Advise patients who do not meet the recommendations to increase their physical activity gradually to a specified minimal level, and tailor the recommendations according to their medical conditions. (3) Assess the next step or steps a patient needs to take to become more active. (4) Assist the patient in taking these steps. (5) Arrange an appointment to follow up on efforts to increase activity.

Health care providers should ask and advise patients about physical activity regularly. One quality-of-care measure assesses whether asking and advising are done at least once a year in older adults. Some recommend that physical activity should be a "vital sign" that is assessed at every visit. Studies consistently report that adults (especially older adults) identify their health care providers as an important source of advice on physical activity.

Nevertheless, the U.S. Preventive Services Task Force concluded that the benefit of routine counseling in the primary care setting is small.[10] The benefit is higher, however, if counseling is provided only when patients request it.

Exercise Prescription

For patients who want to exercise, a clinician can provide an exercise prescription. The prescription includes (1) the type, frequency, duration, and intensity of aerobic exercise; (2) the exercise movements (e.g., bench press), repetitions, and sets for resistance exercise; (3) other exercises such as stretching, balance exercises, warm-up, and cool-down; and (4) risk management strategies, such as increasing levels of activity gradually over time.

Lifestyle Prescription

A lifestyle prescription refers to approaches that integrate physical activity into daily life. For example, rather than walking specifically for exercise, a person walks to work or walks for pleasure as a recreational activity. Common ways to integrate physical activity into daily life are walking and biking for transportation and performing yard work and gardening.

Tailoring the Recommendation

Recommendations need to be tailored to individual abilities, individual preferences, medical conditions, and behavior techniques that improve adherence. Randomized trials show that home-based programs are superior to center-based programs in terms of long-term adherence.[A] Although center-based programs are preferred by some, in most cases they serve a short-term purpose, such as assisting adults to initiate regular exercise.

A target level of physical activity below that of preventive recommendations is appropriate for adults with very low fitness, a large burden of chronic disease (e.g., severe chronic obstructive lung disease), or major functional limitations. An assessment of the nature of the activity limitation and the individual's capabilities and preferences can determine the target activity level and other details of the activity recommendation. Often, promoting physical activity in such adults relies on health care and community resources designed for people with preexisting limitations, such as cardiac rehabilitation, pulmonary rehabilitation, and exercise classes for adults with arthritis.

Risk Management

Strategies to reduce injury include increasing physical activity gradually over time, selecting activities in which collision or contact with people or objects is unusual, increasing physical fitness, using appropriate gear and sports equipment (e.g., bike helmets), engaging in activities in safe environments, and following basic safety rules and policies. Popular activities such as walking, biking, swimming, and gardening have a low risk for injury. When increasing the level of physical activity, the guidelines recommend using relative intensity to determine the level of effort, starting with relatively moderate-intensity activity, then increasing the duration and frequency first and the intensity last. In general, adding 5 to 15 minutes of moderate-intensity activity per session, two to three times a week, to a person's usual activities carries a low risk for musculoskeletal injury and no known risk for sudden cardiac death.[8]

TABLE 16-3 KEY PHYSICAL ACTIVITY GUIDELINES FOR ADULTS

All adults should avoid inactivity. Some physical activity is better than none, and adults who participate in any amount of physical activity gain some health benefits.
For substantial health benefits, adults should do at least 150 min (2.5 hr)/wk of moderate-intensity aerobic activity or 75 min (1.25 hr)/wk of vigorous-intensity aerobic activity, or an equivalent combination of moderate- and vigorous-intensity aerobic activity.
Aerobic activity should be performed in episodes lasting at least 10 min and should be spread throughout the week.
For additional and more extensive health benefits, adults should increase their aerobic physical activity to 300 min (5 hr)/wk of moderate-intensity or 150 min (2.5 hr)/wk of vigorous-intensity aerobic physical activity, or an equivalent combination of moderate- and vigorous-intensity activity. Additional health benefits are gained by engaging in physical activity beyond this amount.
Adults should also do muscle-strengthening activities that are moderate or high intensity and involve all major muscle groups on 2 or more days/wk because these activities provide additional health benefits.

From U.S. Department of Health and Human Services. *2008 Physical Activity Guidelines for Americans.* http://www.health.gov/paguidelines.

There is no evidence of the protective value of a medical consultation or of supervised exercise in healthy people of any age who seek to increase their level of physical activity. The U.S. Preventive Services Task Force recommended against routine screening for coronary disease in adults at low risk for it and concluded that in adults at high risk for coronary disease, there is insufficient evidence to recommend for or against screening with resting electrocardiography or an exercise treadmill test.[11]

Coordination between Medical Care and Community

Many factors affecting physical activity levels are difficult to influence in medical care settings, such as the characteristics of the communal environment (e.g., parks and recreational facilities) and the social environment (e.g., crime and social support). Community-level interventions that address such characteristics are essential to promoting physical activity. Effective community-based interventions include school physical education, social support interventions, community-wide campaigns, enhancement of access to places where physical activity is possible, and interventions that involve community design, such as improving the connectivity of streets and the walkability of neighborhoods.[12] Medical care and community efforts should be synergistic and mutually supportive. For example, health plans should be advocates for evidence-based community interventions. Community programs should serve as resources for evidence-based therapeutic activity for selected chronically ill adults, such as exercise classes designed to reduce the risk for falls.

REVIEW QUESTIONS

1. A 50-year-old man seeks advice about increasing his level of physical activity. While reading about exercise on the Internet, he noted that several websites advised: "consult your physician prior to starting an exercise program." Currently, he rarely engages in moderate to vigorous physical activity, except occasionally on weekends when he does several hours of yard work. He has experienced gradual weight gain over the past two decades, and his body mass index is 28. His medical history is unremarkable except for high blood pressure, which is well controlled by hydrochlorothiazide. He is specifically interested in advice about exercise-related injuries. As a young man, he jogged regularly but had problems with pain in his knees. He also hopes he can lose weight by exercising more. Based the history and the *2008 Physical Activity Guidelines for Americans*, which of the following statements is appropriate to include in your advice to this man?

A. He should regularly perform moderate to vigorous intensity aerobic activity. He should choose a type or types he prefers and spread the aerobic activity throughout the week.
B. To determine the intensity (level of effort) of his activity, his only option is to monitor his heart rate.
C. Vigorous-intensity activity is preferable in adults his age. His goal should be to get at least 60 minutes of vigorous activity each week.
D. Aerobic activity is important, but he should also do muscle strengthening exercises (such as weight training) 3 days per week, with two sets of 10 repetitions for each muscle group.
E. If he is considering getting his physical activity by walking, his goal should be to walk at least 30 minutes a day on at least 5 days per week.

Answer: A This advice is relevant given the man's history of concentrated yard work because the guidelines explicitly discourage large amounts of physical activity in a single day (so-called weekend warriors). B is incorrect because adults can use either absolute or relative intensity to guide their level of effort (heart rate monitoring is the most common way to assess relative intensity). C is incorrect in two ways—the guidelines do *not* state that vigorous activity is preferable, and the guidelines for vigorous activity are 75 minutes per week. D is incorrect in two ways—muscle strengthening exercises need to be on only 2 days per week, and the key guidelines do not have a requirement for two sets for each muscle group. E is incorrect because the current guidelines no longer require physical activity on "most days of the week" or "at least 5 days per week."

2. In asymptomatic healthy adults, an evidence-based approach to reducing the risk for activity-related injuries includes which of the following?

A. Gradually increasing the physical activity level over time
B. Prescribing flexibility exercises
C. Screening for coronary artery disease using either an exercise test or electron-beam computed tomography
D. Starting with supervised exercise and then transitioning to unsupervised
E. None of the above

Answer: A Gradually increasing physical activity over time is a key guideline for injury prevention. There is no evidence that flexibility exercises have health benefits, including no evidence that they prevent injuries. The U.S. Preventive Services Task Force does not recommend routine screening for coronary artery disease using an exercise treadmill test or using electron-beam computed tomography. There is insufficient evidence that supervised exercise reduces injury risk in healthy adults.

3. Which one of the following statements about the benefits and risks of physical activity is true?

A. The overall risk for sudden death is higher in people who exercise regularly.
B. The total volume of physical activity is the main determinant of health benefits.
C. Obese adults do not obtain benefits from physical activity unless they lose weight.
D. The benefits of being active at less than recommended levels are so small that it is of little value to recommend and promote physical activity in people who are not capable of meeting guidelines.
E. The benefits of increasing physical activity do not depend on current level of activity. A person who increases physical activity from 0 minutes to 30 minutes a day obtains the same health benefits as a person who increases activity from 120 minutes a day to 150 minutes per day.

Answer: B The overall risk for sudden death is lower in people who have a higher total volume of exercise. The health benefits of physical activity are independent of other risk factors, and obese adults obtain benefits from physical activity even if obesity persists. Consistent with the dose-response effect, there are meaningful benefits from obtaining less than the recommended amounts of activity. There is a curvilinear dose-response relationship, and the marginal health benefits of increasing activity are less at high levels of physical activity.

4. Which one of the following is recommended for the promotion of physical activity in clinical settings?

A. Counseling and assisting virtually all patients to be physically active with techniques such as motivational interviewing
B. Recommending people start with moderate-intensity activities such as walking, but advising virtually all patients gradually to shift to doing mainly vigorous intensity activity
C. Paying little attention to community resources such as access to parks, gyms, and multiuse trials because there is little scientific evidence that they influence activity
D. Advising virtually all patients to engage in regular physical activity, with the specific activity recommendation based on integrating public health guidelines for prevention with any applicable therapeutic guidelines
E. Emphasizing exercise prescription and exercise classes because most people prefer these activities over lifestyle activities such as walking for transportation and gardening

Answer: D The physician should advise patients regarding the types and amounts of activity appropriate for them, specifically taking into account chronic diseases and activity limitations in making these recommendations. The U.S. Preventive Services Task Force does not recommend exercise counseling for all patients. There is strong evidence that access to community resources affects physical activity levels. Most patients prefer home-based exercise rather than exercise classes. Vigorous activity is not recommended for all adults.

5. Which one of the following statements is true about the use of physical activity to reduce the risk for falls and functional limitations?

A. In overweight and obese older adults with physical functional limitations, weight loss is more important than physical activity in improving function.
B. The fact that falls are more likely during activities such as walking explains why exercise programs in older adults do not reduce risk for falls.
C. Because gait speed in older adults is mainly determined by leg length, it is not a useful measure of mobility or mortality risk.
D. Low fitness (low exercise capacity) does not significantly affect the risk for mortality and is mainly important because it causes functional limitations.
E. Performing Tai Chi exercises can reduce the risk for falls in elderly people.

Answer: E Tai Chi is an evidence-based method for reducing the risk for falls in elderly people. Weight loss is not more important than physical activity in promoting function. Exercise programs, including balance exercises, reduce the risk for falls. Exercise increases gait speed, and better gait speed is a strong predictor of lower mortality. Low physical fitness is associated with higher mortality.

ADOLESCENT MEDICINE

DEBRA K. KATZMAN AND LAWRENCE S. NEINSTEIN

Adolescence, a period of transition between childhood and adulthood, is marked by critical biologic, psychological, social, and cognitive changes. During this unique developmental period, patterns of behaviors and lifestyle choices are established that can influence current and future health, and unique medical and psychological problems can emerge.[1] Adult-oriented health care providers play a pivotal role in engaging youth in their health and in providing health care to adolescents and young adults.

NORMAL PHYSICAL GROWTH AND DEVELOPMENT

Biologic growth and development in adolescents are signified by the onset of puberty (Chapter 235), which varies temporally among adolescents and explains why adolescents of the same chronologic age can vary greatly in physical appearance. The first visible sign of puberty among girls is usually thelarche, or the development of breast buds, which occurs on average at 10.5 years in white girls and 1 year earlier in African American girls (Chapter 235).

Menarche occurs 2 to 4 years after the initial appearance of breast buds and pubic hair. The average age of menarche is 12.9 years for white girls and 12.2 years for African American girls. Menstrual periods are not always regular during the first 2 years after menarche. At menarche, only 20% of cycles are ovulatory; it may take up to another 4 years for 80% of cycles to be ovulatory. The average length for the completion of puberty in girls is 4 years (range, 1.5 to 8.0 years).

Puberty begins about 2 years later in boys than in girls. The first physical sign of puberty in boys, testicular enlargement and thinning of the scrotum, occurs at 11.5 years. Adrenarche occurs 6 months later at an average age of 12.0 to 12.5 years (Chapter 234). Facial hair starts to grow about 3 years after pubic hair. The completion of puberty in boys can take an average of 3 years (range, 2 to 5 years).

Pubertal weight gain accounts for about half of a person's ideal adult body weight. Peak weight gain follows the linear growth spurt by 3 to 6 months in adolescent girls and by about 3 months in adolescent boys. The average weight gain during puberty among adolescent girls is 15 to 55 lb or 7 to 25 kg (mean gain, 38.5 lb or 17.5 kg). Overall, adolescent boys gain 15 to 65 lb or 7 to 30 kg during puberty (mean gain, 52.2 lb or 23.7 kg).

Boys' body fat levels decrease during adolescence, dropping to 12% body fat by the end of puberty. On average, adolescent girls' lean body mass falls from 80 to 75%, whereas their average body fat levels increase from 16 to 27% by the end of adolescence. By the time adolescent girls are 16 years of age and adolescent boys are 18 years of age, they have accrued more than 90% of their adult skeletal mass.

Sexual maturity ratings (SMRs), also known as Tanner staging, are used to describe the progression of secondary sexual characteristics that occur in adolescents, irrespective of chronologic age. SMR is based on the development of breasts and the appearance of pubic hair among girls (Fig. 17-1) and on testicular and penile development and the appearance of pubic hair among boys (Fig. 17-2). SMR 1 corresponds to the prepubertal stage; puberty has not begun, and no sexual development has occurred. SMR 2 to SMR 5 indicate the progression of puberty to adulthood. Once young people reach SMR 5, they have fully developed secondary sexual characteristics. Sexual maturation correlates with linear growth, changes in weight and body composition, and hormonal changes. Sexual maturation provides important assurance of the normal progression of puberty or identification of abnormal pubertal development.[2]

NORMAL PSYCHOSOCIAL DEVELOPMENT

Adolescence is often divided into three psychosocial developmental phases: early adolescence (11 to 13 years), middle adolescence (14 to 16 years), and late adolescence (17 to 21 years). In early adolescence, adolescents begin to separate from their parents and establish an individual identity. As adolescents pull away from their parents in search of their own identity, their peer group takes on an important and special significance.

At the beginning of adolescence, cognitive abilities are dominated by concrete thinking. Young adolescents lack abstract reasoning capabilities, problem-solving skills needed to overcome barriers to behavioral changes, and the ability to appreciate how their current behaviors can affect their future health status.

Middle adolescence is characterized by growth in emotional autonomy and increasing separation from family. The adolescents' peer groups play a powerful role, and adolescents are increasingly involved in partnering relationships that include dating, sexual experimentation, and adverse health behaviors such as smoking cigarettes, drinking alcohol, using street drugs, and being truant. Abstract reasoning skills emerge but often regress to concrete thinking when adolescents are faced with stressful situations. These adolescents begin to understand the relationship between health behaviors and future health status, but peer pressure may make it challenging for them to make appropriate health-related choices.

During late adolescence, young people become increasingly more economically and emotionally independent. Peer group values become less important, and young people spend more time in a relationship with one person. The late stage of adolescence is characterized by the development of a strong personal identity. Abstract reasoning skills expand, and older adolescents have problem-solving skills that help them overcome challenges to behavioral change.

VITAL STATISTICS

Although adolescents and young adults are generally perceived to be healthy, their morbidity and mortality are often the result of risky behaviors and social forces (Table 17-1).[3] Unintentional injury, homicide, and suicide are the leading causes of death in 15- to 24-year-olds and account for more than 70% of all adolescent and young adult deaths. About 75% of these causes of death and injury are preventable.

Unintentional and Intentional Injuries

Unintentional injuries account for 44% of all injury deaths to children and adolescents. For every childhood death caused by injury, another 34 hospitalizations and 1000 emergency department visits occur. Major causes of unintentional injuries to adolescents include motor vehicle accidents, being struck by or against an object or person, cuts from sharp objects, and falls. Athletic injuries, which also are frequent, can be reduced by targeted prevention programs. Factors that contribute to adolescent injuries include socioeconomic factors (poor adolescents are at greatest risk for injury), environmental factors (hazards such as all-terrain vehicles, backyard swimming pools, firearms, kerosene heaters, and gang activity), school environment, and developmental factors.

About 20% of all adolescents, especially adolescent girls in heterosexual relationships, report having experienced either psychological or physical violence from a dating partner. About 20 to 30% of students in grades 6 to 10 are involved in bullying, as a bully, victim, or bully-victim (those who are both aggressive to peers and victimized by peers). For younger adolescents, bullying can lead to a significantly higher risk of psychosomatic problems.

Suicide (Chapter 397) is the second leading cause of death among adolescents and young adults 15 to 24 years of age. Native Americans and white youth 15 to 24 years of age have the highest suicides rates, whereas African American youth 15 to 19 years of age and Asian youth 20 to 24 years of age have the lowest. The estimated ratio of attempted-to-completed suicides among adolescents ranges between 50:1 and 100:1. The most common methods used in suicide attempts are drugs and alcohol, whereas suffocation, hanging, or use of firearms is associated with completed suicides. Death rates caused by firearms are eight times higher in adolescent boys than in adolescent girls.

Homicide is the third leading cause of death in the 15- to 24-year-old U.S. population and the number one cause of death among African American males 15 to 24 years of age. About 75% of homicides in older adolescents and young adults involve firearms.

Clinicians should discuss the impact of alcohol and drugs on driving and stress the importance of routine use of seat belts when driving in a motor vehicle. Clinicians also should discuss safety during sports activities, such as use of bicycle helmets and sports-related protective gear.

Other Diseases

Excluding intentional and unintentional injuries, cancer is the leading cause of death in adolescents and is the leading cause of death by disease. Cancers with an increased incidence in adolescents include Hodgkin lymphoma

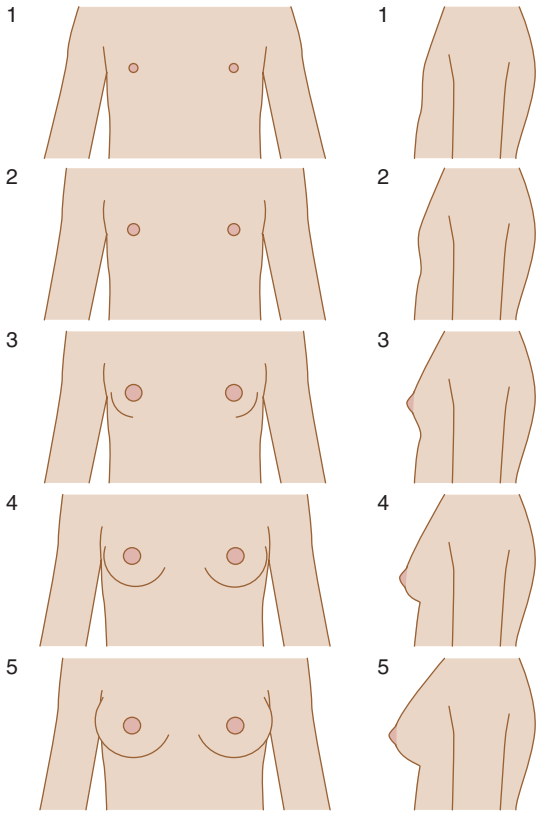

FIGURE 17-1. Female breast development. *Sexual maturity rating 1 (SMR 1)*: Preadolescent; no glandular tissue. Areola and papilla: Areola conforms to general chest line. *SMR 2:* Breast buds appear; areola is slightly widened and projects as small mound. *SMR 3:* Enlargement of the entire breast with protrusion of the papilla or of the nipple. Breast and areola enlarge with no separation of their contours. *SMR 4:* Enlargement of the breast and projection of areola and papilla as a secondary mound. *SMR 5:* Adult configuration of the breast with protrusion of the nipple; areola no longer projects separately from remainder of breast. (Redrawn from Daniel WA, Paulshock BZ. A physician's guide to sexual maturity rating. Patient Care. 1979;30:122. Original illustration by Paul Singh-Roy.)

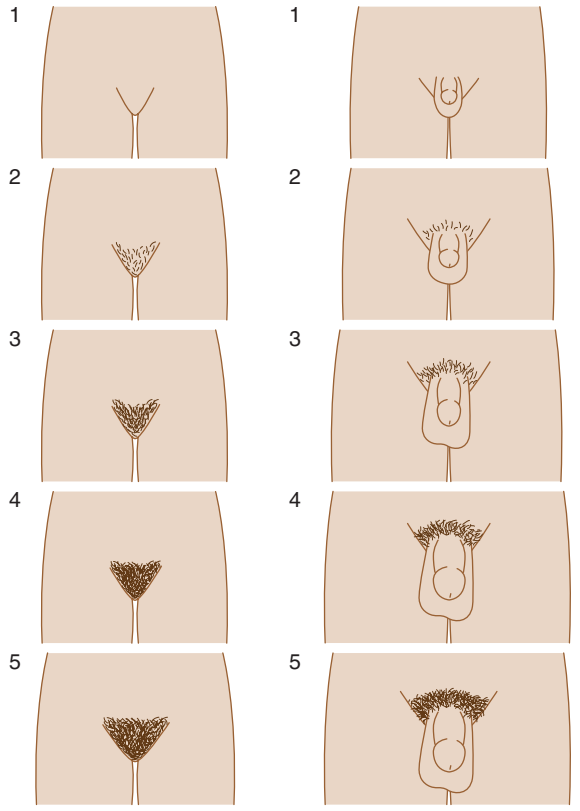

FIGURE 17-2. Female and male pubic hair development. *Sexual maturity rating 1 (SMR 1):* Prepubertal; no pubic hair. *SMR 2:* Small amount of scanty, long, slightly pigmented, along the base of the scrotum and phallus in the male and the medial border of the labia majora in females. *SMR 3:* Darker, coarser, starts to curl, small amount, extending laterally. *SMR 4:* Coarse, curly; resembles adult type but does not extend to the medial surface of the thighs. *SMR 5:* Abundant, adult-type pattern; hair extends onto the medial aspect of the thighs. ***Right,* Male genital development.** *SMR 1:* Penis preadolescent. Testicular volume <4 mL. *SMR 2:* Penis slight or no enlargement. Beginning enlargement of testes; testicular volume 4 to 8 mL; scrotal skin reddened, thinner. *SMR 3:* Penis increased in length. Testicular volume 10 to 15 mL. Further enlargement of scrotum. *SMR 4:* Penis larger in breadth, glans penis develops. Testes and scrotum nearly adult; testicular volume 12-20 mL. *SMR 5:* Penis adult size; testicular volume greater than 25 mL. (Redrawn from Daniel WA, Paulshock BZ. A physician's guide to sexual maturity rating. Patient Care. 1979;30:122. Original illustration by Paul Singh-Roy.)

(Chapter 186), germ cell tumors (Chapter 200), central nervous system tumors (Chapter 189), non-Hodgkin lymphoma (Chapter 185), thyroid cancer (Chapter 226), malignant melanoma (Chapter 203), and acute lymphoblastic leukemia (Chapter 183). HIV infection continues to be one of the 10 leading causes of death among people 15 to 24 years of age.

APPROACH TO THE ADOLESCENT PATIENT

When interviewing adolescent patients, the clinician should consider the adolescents' physical, cognitive, and psychosocial developmental stage; their growing autonomy and increasing role in taking responsibility for their own health and well-being; and their individual progression from childhood to adulthood. Chronologic age is not a guarantee that all adolescents will be at the same stage of physical, cognitive, and psychosocial development. The clinician should offer adolescent health care in a sensitive, flexible, and developmentally and culturally appropriate manner.

The clinician can meet with the adolescent alone at first to give the adolescent the message that she or he is the patient and the clinician is most eager to hear what the adolescent has to say. Conversely, the clinician can meet with the adolescent and her or his parents or guardians together for the initial part of the interview and then meet with the adolescent alone; this approach permits the clinician to develop an understanding of the reason for the visit from the perspective of the adolescent and his or her parents or guardians and to communicate that input from both the adolescent and the parents or guardians is highly valued. This approach also provides an opportunity for the clinician to observe the interaction between the adolescent and parents or guardians. The final approach to the interview is to greet the adolescent and family and request a meeting with the parents or guardians alone. This approach allows the parents or guardians to discuss concerns about the adolescent that they may not feel comfortable raising in the presence of the adolescent. Having this information may improve the focus of the visit. In this approach, the encounter with the parents or guardians is then followed by the clinician's meeting with the adolescent alone. With this interview structure, it is important that the adolescent be present from the time he or she meets with the clinician until the end of the visit, so that the adolescent does not perceive a breach of confidentiality.

TABLE 17-1 LEADING CAUSES OF DEATH IN U.S. ADOLESCENTS

CAUSE	PERCENTAGE OF DEATHS IN YOUTH AGED 15-24 YEARS
Unintentional injury	40.6
Suicide	15.8
Homicide	15.2
Malignant neoplasias	5.4
Diseases of the heart	3.2
Congenital anomalies	1.4
Cerebrovascular diseases	0.6
Pregnancy, childbirth, and the puerperium	0.6
All other causes	15.7

From Hoyert DL, Xu J. Deaths: preliminary data for 2011. National Vital Statistics Reports. Hyattsville, MD: National Center for Health Statistics; 2012.

Confidentiality

Issues of consent and confidentiality are central in the physician-adolescent interaction. Adolescents appreciate clinicians whom they trust and who can

assure them of confidentiality. When guaranteed confidentiality, adolescents are more likely to seek necessary medical care, to disclose sensitive information, and to trust their clinician. Under these circumstances, most adolescents will involve their parents in their care. Parents appreciate education about the concept of confidentiality and recognize the importance of allowing the adolescent the opportunity to speak alone with the clinician. Confidentiality is also important for clinicians. To make an accurate diagnosis and to provide treatment, the clinician must obtain all relevant information from the adolescent. If the adolescent fears that such information will not be kept confidential, she or he may not provide all the necessary factual information.

Confidentiality and defining the limits of confidentiality should be discussed with the adolescent and his or her parents or guardians at the beginning of the interview. The adolescent and family need to know that the clinician will intervene if he or she believes that the adolescent's actions may cause him or her, or another person, significant harm. Examples of situations in which the clinician would not maintain confidentiality when dealing with young people include disclosure of current suicidal or homicidal intent.

Those who work with young people must have a clear understanding of consent and confidentiality and should make sure that adolescents are aware of confidentiality policies and practices. The duty of confidentiality does not preclude encouraging and empowering adolescents to talk to their parents or guardians about important health care issues and to include them in discussions of these issues. The legal definition of confidentiality varies, depending on geographic location, and clinicians should be familiar with the local laws.

Another goal of the interview is to build rapport with the adolescent and his or her parents or guardians. Clinicians can establish rapport with the adolescent at the start of the interview by creating an environment that is nonjudgmental, unintimidating, and supportive. The clinician's genuine interest in the adolescent is paramount. It is helpful to encourage the adolescent to talk about himself or herself—friends, hobbies, school. The clinician should listen carefully to the adolescent's statements and feelings. Sensitivity to and understanding of the adolescent's developmental stage and cultural background are important in interviewing an adolescent and interpreting answers accurately. The clinician should be respectful of the adolescent's growing need to be independent and desire to be treated as an individual person. Taking the time to build rapport is key to engaging the adolescent in a discussion of his or her personal health concerns with the clinician. It is the clinician's responsibility to familiarize himself or herself with the legal issues of confidentiality (as they relate to the adolescent patient and his or her parents or guardians) in his or her locality.

Preventive Health Care

Preventive health care for adolescents (Chapters 15 and 18) should promote physical and mental health and healthy physical, psychological, and social growth and development.[4] Positive behaviors such as exercise (Chapter 16) and nutritious eating (Chapter 213) should be encouraged, and health risk behaviors such as unsafe driving, use of tobacco (Chapter 32), unsafe sexual behaviors, and excess alcohol (Chapter 33) should be discouraged. Because lifelong health habits are established during adolescence, it is an important time to invest in health promotion and preventive services.

The U.S. Preventive Services Task Force recommends screening and counseling of all adolescents about depression and obesity and ensuring that all adolescents are up-to-date on their immunizations for tetanus, diphtheria, pertussis, varicella, measles, mumps, rubella, hepatitis B, meningococcus, polio, and human papillomavirus (HPV; Chapter 18). In addition, at-risk adolescents should be counseled about sexually transmitted diseases (e.g., HIV, chlamydia, gonorrhea, and syphilis) and advised about immunizations for influenza, pneumococcus, and hepatitis A.[5] Influenza immunization is recommended for all adolescents unless there is a vaccine shortage, in which case at-risk adolescents should be vaccinated first.

Components of the Adolescent Care Health Visit

History

Open-ended, nonjudgmental, developmentally appropriate, and gender-neutral questions help put the adolescent at ease and produce informative answers (Chapter 15). In addition to a standard medical history, the assessment should include a psychosocial history from the adolescent, either through a screening questionnaire or during the interview with the adolescent alone. The HEEADSSS assessment, which is a valuable screening tool for obtaining a comprehensive psychosocial history, covers the following topics:

- **H**ome: family members, living arrangements, and relationships
- **E**ducation/**E**mployment: academic or vocational success and future plans
- **E**ating: concerns about weight or body image or disordered eating attitudes and behaviors
- **A**ctivities: recreational activities, dating, and relationships
- **D**rugs: use of tobacco, alcohol, illicit drugs, anabolic steroids, and driving while intoxicated
- **S**exuality: sexual orientation, sexual activity, and sexual abuse
- **S**uicide (mental health): feelings of sadness, loneliness, depression; or suicidal ideation, attempts, and non-suicidal self-injury
- **S**afety: risk of unintentional injury or violence, fighting; or weapon carrying

Physical Examination

In general, the adolescent physical examination should occur without a parent or guardian present. In some situations, the adolescent is asked whether he or she would prefer to have a parent in the room during the physical examination. A male clinician should request that a female health care provider be present during the physical examination of a female patient, especially during the breast and genital examination. In theory, a female clinician should request a male health care provider be present during the genital examination of a male patient.

Care should be taken to ensure the adolescent's privacy. Providing an examination gown that covers the trunk and genital area is important. Talking with the adolescent during the examination also tends to increase comfort; explaining the procedures and commenting on the results are helpful. A comprehensive physical examination (Chapter 15) should include measuring the adolescent's weight and height, calculating his or her body mass index, plotting these measurements on standardized growth charts, and determining the adolescent's SMR.

The most recent American guidelines for cervical cancer screening recommend against screening women younger than 21 years.[6] These recommendations do not apply to young women with previously abnormal test results on cervical screening or to women who are immunosuppressed by HIV infection, organ transplantation, chemotherapy, or chronic use of corticosteroids. Indications for a pelvic examination in an adolescent include symptoms of vaginal or uterine infection, menstrual irregularities (e.g., amenorrhea, dysfunctional uterine bleeding, menorrhagia, and severe dysmenorrhea), undiagnosed abdominal or pelvic pain, tenderness, mass, trauma, sexual abuse, or assault. A careful history and a urine or patient-obtained specimen may be an alternative to the pelvic examination.

Conclusion of the Health Visit

At the conclusion of the adolescent health visit, the clinician should review the findings with the adolescent and talk about what happens next. The adolescent should have the opportunity to ask questions, get clarification, make comments, and respond to suggestions. The clinician should discuss with the adolescent what information will remain confidential. The clinician should then meet with the adolescent and the parents or guardians (if they have accompanied the adolescent to the health visit) to review the outcomes and to discuss the nonconfidential issues.

REPRODUCTIVE HEALTH

Reproductive health care includes issues of adolescent sexual development, adolescent sexual behaviors, adolescent pregnancy, and contraception. In the United States, nearly 50% of high-school boys and girls in grades 9 to 12 have had vaginal intercourse at least once. This number increases from 38% of boys and 28% of girls in grade 9 to about 63% of both boys and girls by their senior year. In addition, 3.4% of girls and 9% of boys in grades 9 to 12 started having sex before they were 13 years old, 15% of adolescents have had four or more sex partners during their lives, and 40% of sexually active high-school students did not use a condom when they last had sexual intercourse. About 60% of adolescent girls who are 13 years of age or younger when they first had sexual intercourse report having involuntary intercourse. Adolescents are more likely to report engaging in oral than in vaginal sex because they perceive oral sex as significantly less risky (fewer health, social, and emotional consequences) than vaginal sex, but adolescents who engage in oral sex also are more likely to engage in vaginal sex.[7]

Every year, about 750,000 pregnancies occur in girls 15 to 19 years of age in the United States. About 50% of these pregnancies result in a live birth, about 35% end with an abortion, and about 15% end with a miscarriage or stillbirth. During the past 20 years, teenage pregnancy rates in the United States have declined by 42%.[8] The birth rate for mothers 15 to 19 years of age decreased by about 50%, from about 62 per 100,000 to about 31 per 100,000.

Abortion rates also have decreased. Most of these decreases are because of increased use of effective contraception and decreased sexual activity. Adolescent pregnancy is more common among black and Hispanic girls as well as among girls from low-income families.

Positive outcomes of adolescent pregnancies are enhanced with good prenatal care, adequate initial and follow-up prenatal visits, nutritional counseling, assessment of psychosocial issues, and substance abuse counseling. Adolescents younger than 15 years are at increased risk for premature and low-birthweight infants; those older than 15 years who have adequate prenatal care do not have increased adverse outcomes.

Contraception

The most commonly used contraceptive methods in adolescents are oral contraceptive pills and condoms, although new hormonal delivery systems, such as transdermal patches, vaginal rings, and long-acting reversible contraceptives, are convenient and effective (Chapter 238). Long-acting reversible contraceptive methods (intrauterine devices and contraceptive implants) are increasingly popular in adolescents, who are at high risk of unintended pregnancy. Routine counseling about emergency contraception is an important part of the public health strategy to reduce teen pregnancy (Chapter 238).

Sexually Transmitted Diseases

Every year, about 4 million adolescents in the United States acquire a sexually transmitted disease (Chapter 285), representing 25% of the total cases of sexually transmitted disease diagnosed annually. *Chlamydia trachomatis,* which is the most commonly reported bacterial sexually transmitted disease, is reported annually in about 3.4% of female adolescents 15 to 19 years of age and 0.6% of male adolescents of the same age. The annual incidence of gonorrhea is about 0.6% for female adolescents 15 to 19 years of age and 0.25 % for adolescent males of the same age. In adolescents, HIV infection (Chapter 384) is contracted primarily as a sexually transmitted disease, and adolescents and young adults 15 to 24 years of age represent 14% of all new diagnoses of HIV infection in the United States. HPV (Chapter 373), which is the most prevalent of all sexually transmitted diseases in 15- to 24-year-olds, has a prevalence of about 20% in adolescent girls 14 to 17 years of age.

Adolescents are at greater risk of acquiring sexually transmitted diseases because they are more likely to engage in unprotected sexual intercourse with concurrent partners who have multiple other partners. Adolescent girls may have persistent vaginal columnar epithelium that is more susceptible than squamous epithelium to *Neisseria gonorrhoeae, C. trachomatis*, and HPV as well as lower levels of immunoglobulin A in their cervical mucus. Treatment may be delayed owing to an inability to access confidential health care services, lack of health care coverage, poverty, and drug trafficking and use.

Chlamydial infections (Chapter 318), often asymptomatic or minimally symptomatic in women, usually are manifested with a vaginal discharge in young adolescent girls. Otherwise, clinical presentations and treatments of sexually transmitted diseases (Chapter 285) in adolescents are similar to those in adults.

About 20% of adolescents given prescriptions for a sexually transmitted disease treatment fail to fill their prescriptions. Therefore, whenever it is available, an observed single-dose therapy is recommended.[9] In addition, expedited partner therapy, which is the treatment of sexual partners without requiring a prior clinical evaluation or prevention counseling, reduces the level of recurrent sexually transmitted diseases better than does standard management. Clinicians should consider the use of expedited partner therapy for partners exposed within 60 days to heterosexual males and females with chlamydia or gonorrhea infections when in-person evaluation and treatment are unlikely (Chapter 285).

ADOLESCENT OBESITY AND EATING DISORDERS

More than one third of children and adolescents are overweight or obese. Obese adolescents are significantly more likely to become severely obese in adulthood. Interventions should focus on changing behavior, increasing physical activity, and modifying the diet. Randomized trials also show that substituting sugar-free beverages for sugar-sweetened beverages can reduce short-term weight gain,■ but family-based behavioral treatment programs offer the best short- and long-term success for weight management.■ In extreme cases, pharmacotherapy and even bariatric surgery may be considered in the therapeutic plan (Chapter 220).

Eating disorders (Chapter 219) commonly begin during adolescence.[10] For adolescent-onset eating disorders, early recognition and aggressive treatment are critical to a successful outcome. The medical complications of eating disorders in adolescents include growth retardation, pubertal delay, low bone mineral density, and changes in brain structure and cognitive function. These complications, which occur early in the disease process, may not be completely reversible, thereby underscoring the need for early and aggressive treatment.

The goals of treatment are to restore physical health, normal eating behavior patterns, and mental health and to reduce the impact of the eating disorder on the quality of life. Adolescents should be treated at a facility where the health professionals understand eating disorders and have experience in treating adolescents. Successful management strategies for adolescents with eating disorders include early restoration of a normal nutritional and physiologic state, involvement of the family in the treatment, and incorporation of an interdisciplinary team in the treatment. Family-based therapy is an effective treatment for adolescents with eating disorders and helps protect against relapse.■

SUBSTANCE ABUSE

Nearly half of adolescents try an illicit drug (Chapter 34) by the time they finish high school. About 75% of adolescents consume alcohol (Chapter 33) by the end of high school, and about half report having been drunk at least once in their life. Adolescents who begin using alcohol or drugs before 15 years of age are more than five times more likely to develop an addictive disorder later in life compared with those who first use alcohol at 21 years of age. About 45% of adolescents use marijuana, and 20% of 12th graders are current smokers.

Adolescents start using drugs or alcohol primarily because of social pressures but report continuing them to feel good or to cope with difficulties.[11] Boys tend to initiate drug and alcohol use at younger ages than girls do, but once girls begin to experiment, they are just as likely as boys to use drugs. Boys are more likely to consume marijuana, steroids, and smokeless tobacco, whereas girls are more likely to abuse amphetamines and methamphetamine.

Adolescents with poor self-esteem, low motivation, and poor academic achievement have a greater propensity for alcohol and drug abuse than those with positive self-esteem. Adolescents with a family member with a history of alcohol or other drug abuse are at greater risk. Adolescents are less likely to succumb to external pressures toward drug use if they have a strong sense of attachment to parents who clearly communicate their disapproval.

Signs and symptoms suggestive of substance abuse include changes in physical appearance, poor hygiene or dress, wearing long-sleeved shirts to hide scarring at injection sites, persistent cough or bronchitis, difficulty sleeping, sudden weight loss or weight gain, sudden changes in personality, aggressive behavior, irritability, nervousness, giddiness, changes in peer group, increased isolation from peers or family, depression, loss of interest in once favorite activities, decline in performance or attendance at school or work, forgetfulness, increased secretiveness, money or objects disappearing from the household, and prescription drugs that seem to be used up too quickly.

A validated screening tool for alcohol and substance abuse (Table 17-2) should be used in adolescents. Adolescents who answer yes to one of the six questions should receive advice on the adverse effects of substance abuse. Those who answer yes to two or more questions are at high risk and require further assessment or referral (Chapters 33 and 34). Urine drug testing has low sensitivity for detection of drug use, and there is no consensus about its role for screening of adolescents.

Alcohol and drug use contributes to more than 40% of adolescent deaths from motor vehicle crashes, to suicide attempts, and to an increased risk for subsequent use and its related problems in adulthood.

Historically, substance abuse treatment has been based on abstinence. More recently, a harm-reduction approach has gained acceptance. Adolescents discontinue drug and alcohol use mainly because of concern about their negative effects, and community-based interventions can be effective.■ To reduce alcohol abuse over time, individual interventions have a larger impact than family-based interventions.■

CHRONIC ILLNESS AND TRANSITION

The prevalence of chronic diseases in adolescents has increased significantly because advances in medical technology and treatments have increased the survival of young people with childhood diseases formerly considered lethal.

TABLE 17-2 CRAFFT SCREENING TOOL FOR DRUG AND ALCOHOL USE IN ADOLESCENTS

The adolescent is instructed, "Please answer these next questions honestly. Your answers will be kept confidential. During the past 12 months, did you …"
Drink any alcohol (more than a few sips)?
Smoke any marijuana or hashish?
Use anything else to get high?

If the adolescent answers no to the three opening questions, the provider only needs to ask the adolescent the first question—the CAR question. If the adolescent answers yes to any one or more of the three opening questions, the provider asks all six CRAFFT questions.

C—Have you ever ridden in a CAR driven by someone (including yourself) who was "high" or had been using alcohol or drugs?
R—Do you ever use alcohol or drugs to RELAX, feel better about yourself, or fit in?
A—Do you ever use alcohol/drugs while you are by yourself, ALONE?
F—Do you ever FORGET things you did while using alcohol or drugs?
F—Do your family or FRIENDS ever tell you that you should cut down on your drinking or drug use?
T—Have you gotten into TROUBLE while you were using alcohol or drugs?

CRAFFT is a mnemonic acronym of the first letters of key words in the six screening questions. The questions should be asked exactly as written.

About 18% of adolescents in the United States live with a chronic illness. Chronic illness may affect the adolescent's development, or the adolescent's development may affect the illness. For example, cystic fibrosis (Chapter 89) may delay puberty and hinder normal peer development. Puberty can exacerbate diabetes mellitus (Chapter 229). Increased risk-taking by adolescents with diabetes, asthma, or chronic renal failure can hinder their compliance with their medication regimen.

Adolescents in general, and those with special health care needs in particular, require a smooth, seamless, coordinated, and developmentally appropriate transition to the adult health care system. Barriers to a successful transition include a lack of adult physicians who can manage chronic childhood conditions (e.g., congenital heart disease; Chapter 69); patients, families, and pediatric subspecialists who are reluctant to terminate long-standing relationships; and patients and families who are poorly equipped to find their way in the adult health care system. As adolescents move closer to the age of transition, professionals should provide developmentally appropriate information and skills to support them and their families as they negotiate the adult health care system.

Adolescents benefit from an introductory visit with their adult-oriented care provider before leaving the pediatric health care system. This visit should give the adolescent a clearer idea about his or her new role as an adult patient, especially about expectations around decision making, giving consent, and the role of the family in his or her health care. The patient, family, and pediatric and adult health care systems should view the transition as a natural part of the developmental process of care for all adolescents.

REVIEW QUESTIONS

1. A mother brings her 11-year-old daughter to see her physician because she is worried that her daughter has not started puberty. The physician performs a complete physical examination and assures the mother and her daughter that she has started puberty. What is the first visible sign of puberty among girls?

A. Linear growth spurt
B. Menarche
C. Thelarche, the development of breast buds
D. Pubarche, first appearance of pubic hair
E. Weight gain

Answer: C The first visible sign of puberty among girls is usually thelarche, or the development of breast buds, which occurs on average at 10.5 years in white girls and 1 year earlier in African American girls.

2. A 14-year-old girl comes to see you because she has not started her menstrual period. The following statements about menarche are all true except which one?

A. Menarche occurs 2 to 4 years after the initial appearance of breast buds and pubic hair.
B. The average age of menarche is 12.9 years for white girls.
C. The average age of menarche is 12.2 years for African American girls.
D. Menstrual periods are always regular after the onset of menarche.
E. At menarche, only 20% of cycles are ovulatory.

Answer: D Menarche, or the onset of the first menstrual period, occurs 2 to 4 years after the initial appearance of breast buds and pubic hair. The average age of menarche is 12.9 years for white girls and 12.2 years for African American girls. Menstrual periods are not always regular during the first 2 years after menarche. At menarche, only 20% of cycles are ovulatory; it may take up to 4 years for 80% of cycles to be ovulatory. The average length for the completion of puberty in girls is 4 years (range, 1.5 to 8.0 years).

3. An 18-year-old sexually active woman comes to see her physician for a Papanicolaou smear. Her current partner is her first and only sexual partner, and she reports that she and her partner are monogamous. She is taking the oral contraceptive pill and uses the condom every time she has sexual intercourse. In reviewing the most recent American guidelines for cervical cancer recommendations, you realize that performing a Papanicolaou smear does not apply to which of the following circumstances?

A. Young women with symptoms of cervical cancer
B. Women with previous abnormal test results on cervical screening
C. Women who are immunosuppressed by HIV, organ transplantation, chemotherapy, or chronic use of corticosteroids
D. Sexually active women who are practicing safe sex

Answer: D The most recent American guidelines for cervical cancer screening recommend against screening of women younger than 21 years. These recommendations do not apply to young women with symptoms of cervical cancer or previous abnormal test results on cervical screening or to women who are immunosuppressed by HIV, organ transplantation, chemotherapy, or chronic use of corticosteroids. (Saslow D, Solomon D, Lawson HW, et al. American Cancer Society, American Society for Colposcopy and Cervical Pathology, and American Society for Clinical Pathology screening guidelines for the prevention and early detection of cervical cancer. *CA Cancer J Clin.* 2012;62:147-172.)

4. You are working at a university health center caring for students. You learn that this semester a 20-year-old student died of testicular cancer (student A), a 23-year-old student committed suicide (student B), and a 19-year-old student was killed in a car accident (student C). Which of these three students fall in the top three causes of death in young adults?

A. Students A and B (cancer and suicide)
B. Students B and C (suicide and car accident)
C. Students A and C (cancer and car accident)
D. All three students (cancer, suicide, and car accident)
E. None of the students

Answer: B The top three causes of death in adolescents and young adults are unintentional car accidents (most from motor vehicle accidents), suicides, and homicides. These three cause more than 71% of deaths in adolescents and young adults. Cancer deaths in this age group are a distant fourth cause of mortality (see Table 17-1). (Hoyert DL, Xu J. Deaths: preliminary data for 2011. *National Vital Statistics Reports*. Hyattsville, MD: National Center for Health Statistics; 2012.)

18

IMMUNIZATION

RAYMOND A. STRIKAS AND WALTER A. ORENSTEIN

Immunization is one of the most cost-effective means of preventing morbidity and mortality from infectious diseases. Routine immunization, particularly of children, has resulted in decreases of 90% or more in reported cases of measles, mumps, rubella, congenital rubella syndrome, poliomyelitis, tetanus, invasive *Haemophilus influenzae* type b, varicella, hepatitis A, and diphtheria. In many circumstances, immunization in children and adults not only prevents morbidity and mortality but also reduces health care costs in the long run.

GENERAL CHARACTERISTICS OF IMMUNIZATIONS

Immunization protects against disease or the sequelae of disease through the administration of an immunobiologic—a vaccine, toxoid, immune globulin preparation, or antitoxin. Protection induced by immunization can be active or passive.[1]

Active Immunization

Administration of a vaccine or toxoid causes the body to produce an immune response against the infectious agent or its toxins. Vaccines consist of suspensions of live (usually attenuated) or inactivated microorganisms or fractions thereof. Toxoids are modified bacterial toxins that retain immunogenic properties but lack toxicity. Active immunization generally results in long-term immunity, although the onset of protection may be delayed because it takes time for the body to respond. With live attenuated vaccines, small quantities of living organisms multiply within the recipient until an immune response cuts off replication. In most recipients, a single dose of a live vaccine generally induces a long-term immune response that closely parallels natural infection. In contrast, inactivated vaccines and toxoids contain large quantities of antigens. Killed (inactivated) vaccines often require multiple doses.

Passive Immunization

Passive immunization with use of immune globulins or antitoxins delivers preformed antibodies to provide temporary immunity. Immune globulins obtained from human blood may contain antibodies to a variety of agents, depending on the pool of human plasma from which they are prepared. Specific immune globulins are made from the plasma of donors with high levels of antibodies to specific antigens (such as tetanus immune globulin). Most immune globulins must be injected intramuscularly, although intravenous and subcutaneous preparations are also available. Antitoxins are solutions of antibodies derived from animals immunized with specific antigens (e.g., diphtheria antitoxin). Passive immunization usually is indicated to protect individuals immediately before anticipated exposure or shortly after known or suspected exposure to an infectious agent (Table 18-1), when active immunization either is not possible or has not been adequate.

Route and Timing of Vaccination

Each immunobiologic has a preferred site and route of administration. In adults, vaccines containing adjuvants should be injected intramuscularly, preferably in the deltoid muscle. For most adults, intramuscular injections should be administered with a 1- to 1½-inch, 22- to 25-gauge needle. Use of the buttocks is discouraged except when large volumes are required because of the potential for damage to the sciatic nerve and because of diminished immune response to some vaccines (such as hepatitis B), probably because vaccine is injected into fat rather than into muscle. Subcutaneous vaccines are usually administered in the triceps area. In general, inactivated vaccines and toxoids can be given at the same visit at different sites. Live and inactivated vaccines usually can be administered at the same time. For example, measles, mumps, and rubella (MMR) vaccine can be administered at the same time as inactivated poliovirus vaccine and live attenuated varicella vaccine. In general, injected and intranasally administered live vaccines not delivered on the same day should be separated by at least 4 weeks to avoid interference by the second vaccine of viral replication and immunity induced by the first vaccine. Orally administered live vaccines (such as oral typhoid vaccine) can be administered

TABLE 18-1 PASSIVE IMMUNIZATIONS FOR ADULTS

DISEASE	NAME OF MATERIAL	COMMENTS AND USE
Tetanus	Tetanus immune globulin, human	Management of tetanus-prone wounds in persons without adequate prior active immunization and treatment of tetanus
Cytomegalovirus	Cytomegalovirus immune globulin, intravenous	Prophylaxis for bone marrow and kidney transplant recipients
Diphtheria	Diphtheria antitoxin, equine	Treatment of established disease; high frequency of reactions to serum of nonhuman origin; in the United States, available only from CDC
Rabies	Rabies immune globulin, human	Postexposure prophylaxis of animal bites
Measles	Immune globulin, human	Prevention or modification of disease in exposed persons, not for control of outbreaks; particularly indicated for unvaccinated infants aged <12 months, pregnant women without evidence of measles immunity, and severely immunocompromised persons
Hepatitis A	Immune globulin, human	Pre-exposure and postexposure prophylaxis for travelers and others who need protection before immunity can be achieved with hepatitis A vaccine
Hepatitis B	Hepatitis B immune globulin, human	Prophylaxis for needle stick or mucous membrane contact with HBsAg-positive persons, for sexual partners with acute hepatitis B or carriers of hepatitis B, for infants born to mothers who are carriers of HBsAg, for infants whose mother or primary caregiver has acute hepatitis B
Varicella	Varicella-zoster immune globulin (VariZIG)	Persons with underlying disease and at risk for complications from chickenpox who have not had varicella or varicella vaccine and who are exposed to varicella; may be given up to 10 days after exposure to known susceptible adults, particularly if antibody negative; VariZIG is available under IND
Vaccinia	Vaccinia immune globulin	Treatment of eczema vaccinatum, vaccinia necrosum, and severe inadvertent inoculations such as ocular vaccinia after vaccinia (smallpox) vaccination; available only from CDC
Erythroblastosis fetalis	Rh immune globulin	Rh-negative women who give birth to Rh-positive infants or who abort
Hypogammaglobulinemia	Immune globulin, intravenous, subcutaneous	Maintenance therapy
Idiopathic thrombocytopenic purpura	Immune globulin, intravenous	Therapy for acute episodes
Botulism	Heptavalent A, B, C, D, E, F, E, G antitoxin, equine	Treatment of botulism; available through CDC
	Botulism immune globulin for infants	Treatment of botulism in infants
Snakebite	Antivenin, equine (North American coral snake antivenin)	Specific for North American coral snake, *Micrurus fulvius*
Crotalidae, polyvalent	Effective for viper and pit viper bites, including rattlesnakes, copperheads, moccasins	
Spider bite	Antivenin, equine	Specific for black widow spider, *Latrodectus mactans,* and other members of the genus
Scorpion	Fab fragments, equine	Specific for *Centruroides* genus scorpions

CDC = Centers for Disease Control and Prevention; HBsAg = hepatitis B surface antigen; IND = Investigational New Drug.

at any interval before or after live injected or intranasal vaccines. Immune globulin may interfere with the replication of injected live vaccine viruses; ideally, most live vaccines should be administered at least 2 weeks before or 3 to 11 months after immune globulin. Immune globulin does not interfere with the response to yellow fever vaccine and is not believed to interfere with orally or intranasally administered live virus vaccines.

Adverse Reactions

No vaccine is completely safe or completely effective. Adverse reactions fall into three general categories: local, systemic, and allergic. Local reactions are generally the most frequent but least severe. Systemic adverse reactions include fever, malaise, myalgias (muscle pain), headache, and loss of appetite. These symptoms, which are common and nonspecific, may occur in vaccinated persons because of the vaccine or because of something unrelated to the vaccine. Allergic reactions, which are the least frequent but most severe, may be caused by the vaccine antigen itself or by another component of the vaccine, such as the cell culture material, stabilizer, preservative, or antibiotic used to inhibit bacterial growth. Life-threatening allergic reactions occur at a rate of about one per million doses. The risk of an allergic reaction can be minimized by good screening before vaccination. All providers who administer vaccines must have an emergency protocol and supplies to treat anaphylaxis.

Antipyretics should not be administered routinely before or at the time of vaccination because they tend to reduce the immune response,■ but they can be used for the treatment of fever and local discomfort that might occur after vaccination. The egg protein contained in vaccines grown in chicken eggs (influenza and yellow fever vaccines) may cause reactions in persons severely allergic to eggs. In general, persons without anaphylactic-type allergies to eggs can be given these vaccines safely, but persons with anaphylactic reactions to eggs generally should not receive these vaccines except when it is absolutely necessary, and then only under established protocols by physicians who have expertise in such situations. Although measles and mumps vaccines are grown in chick embryo tissue culture, the risk of anaphylaxis even in persons with severe hypersensitivity to eggs is low, so they can be vaccinated without prior testing.

Suspected adverse events temporally related to vaccinations should be reported to the Vaccine Adverse Event Reporting System (at *www.vaers.hhs.gov*). The National Vaccine Injury Compensation Program was established in the 1980's to compensate individuals who experience certain health events after vaccination on a "no-fault" basis. No-fault means that persons filing claims are not required to prove negligence on the part of either the health care provider or manufacturer to receive compensation. The program covers all routinely recommended childhood vaccinations, although adults who receive a covered vaccine may also file a claim. Claims may be based on a Vaccine Injury Table (see *http://www.hrsa.gov/vaccinecompensation/vaccinetable.html*), which lists the adverse events associated with vaccines and is updated periodically.

General Considerations

The major group that makes comprehensive, detailed recommendations regarding immunization of adults is the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention, which

publishes its information in *Morbidity and Mortality Weekly Report* (also available at http://www.cdc.gov/vaccines/schedules/hcp/adult.html). Immunizations for adults depend on age, lifestyle, occupation, and medical conditions. Two adult immunization schedules are available, one based on age group (Fig. 18-1 and E-Table 18-1) and one based on underlying risk (Fig. 18-2 and Table 18-2).[1,2] All adults who have not received a primary series of diphtheria-tetanus-pertussis–containing vaccine as children should receive one dose of combined tetanus and diphtheria-pertussis vaccine (Tdap), followed by a second dose of tetanus and diphtheria toxoids (Td) 4 weeks later, a third Td dose 6 to 12 months later, and a Td booster every 10 years.[3] All adults (and especially health care personnel) who received a diphtheria-tetanus-pertussis (DTaP) vaccine series as children should have a one-time dose of Tdap, followed by Td every 10 years. Persons born in or after 1957 should have evidence of immunity to measles, mumps, and rubella (e.g., documentation of vaccination or presence of antibodies considered compatible with protection). Adults without evidence of immunity to varicella (documentation of age-appropriate vaccination with two doses of varicella vaccine; laboratory evidence of immunity or confirmation of disease; birth in the United States before 1980, except for health care personnel, pregnant women, or immunocompromised persons; or diagnosis or verification of a history of varicella or herpes zoster disease by a health care provider) should receive varicella vaccine.

Pneumococcal polysaccharide vaccine (PPSV23) is indicated for all adults 65 years and older and for younger adults with certain medical conditions that place them at high risk of complications (see Table 18-2). All adults aged 65 years and older and persons 19 years and older with immunocompromising conditions (including chronic renal failure and nephrotic syndrome), functional or anatomic asplenia, cerebrospinal fluid leaks, or cochlear implants should receive a single dose of pneumococcal conjugate vaccine, ideally before receiving pneumococcal polysaccharide vaccine. Adults 65 years and older should receive pneumococcal polysaccharide vaccine 6 to 12 months later. Adults with immunocompromising conditions should also receive a dose of PPSV23 at least 8 weeks later. Immunocompromised adults who already received PPSV23 should still receive pneumococcal conjugate vaccine 1 year or more after the PPSV23 dose; they should be revaccinated with PPSV23 once after pneumococcal conjugate vaccine when 5 years have passed since their first PPSV23 dose.

Influenza vaccination is recommended annually for all persons 6 months of age or older, including all health care personnel. Health care workers exposed to blood or blood products should receive hepatitis B vaccine. Health care workers should also be immune to measles, mumps, rubella, and varicella.

Text continued on page 73

Recommended Adult Immunization Schedule — United States–2014

Note: These recommendations *must* be read with the footnotes that follow containing number of doses, intervals between doses, and other important information.

Recommended adult immunization schedule, by vaccine and age group†

Vaccine ↓ / Age Group →	19–21 years	22–26 years	27–49 years	50–59 years	60–64 years	≥65 years
Influenza †*	1 dose annually					
Tetanus, diphtheria, pertussis (Td/Tdap) †*	Substitute 1-time dose of Tdap for Td booster; then boost with Td every 10 yrs					
Varicella †*	2 doses					
Human papillomavirus (HPV) Female †*	3 doses					
Human papillomavirus (HPV) Male †*	3 doses	3 doses				
Zoster †					1 dose	
Measles, mumps, rubella (MMR) †*	1 or 2 doses					
Pneumococcal 13-valent conjugate (PCV13) †*	1 dose					
Pneumococcal polysaccharide (PPSV23) †	1 or 2 doses					1 dose
Meningococcal †*	1 or more doses					
Hepatitis A †*	2 doses					
Hepatitis B †*	3 doses					
Haemophilus influenzae type b (Hib) †*	1 or 3 doses					

For all persons in this category who meet the age requirements and who lack documentation of vaccination or have no evidence of previous infection; zoster vaccine recommended regardless of prior episode of zoster

Recommended if some other risk factor is present (e.g., on the basis of medical, occupational, lifestyle, or other indications)

No recommendation

*Covered by the Vaccine Injury Compensation Program

†See E-Table 18-1 for additional information.

Report all clinically significant postvaccination reactions to the Vaccine Adverse Event Reporting System (VAERS). Reporting forms and instructions on filing a VAERS report are available at http://www.vaers.hhs.gov or by telephone, 800-822-7967.

Information on how to file a Vaccine Injury Compensation Program claim is available at www.hrsa.gov/vaccinecompensation or by telephone, 800-338-2382. To file a claim for vaccine injury, contact the U.S. Court of Federal Claims, 717 Madison Place, N.W., Washington, D.C. 20005; telephone 202-357-6400.

Additional information about the vaccines in this schedule, extent of available data, and contraindications for vaccination are also available at http://www.cdc.gov/vaccines, or from the CDC-INFO Contact Center at 800-CDC-INFO (800-232-4636) in English or Spanish, 8:00 a.m. – 8:00 p.m. Eastern Time, Monday – Friday, excluding holidays.

Use of trade-names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

The recommendations in this schedule were approved by the Centers for Disease Control and Preventtion's (CDC) Advisory Committee on Immunization Practices (ACIP), the American Academy of Family Physicians (AAFP), the American College of Physicians (ACP), American College of Obstetricians and Gynecologist (ACOG) and American College of Nurse-Midwives (ACNM).

FIGURE 18-1. Recommended adult immunization schedule by vaccine and age group, United States, 2014. See E-Table 18-1 for footnotes. (Adapted from http://www.cdc.gov/vaccines/schedules/downloads/adult/adult-combined-schedule.pdf.)

E-TABLE 18-1 FOOTNOTES RECOMMENDED IMMUNIZATION SCHEDULE FOR ADULTS AGED 19 YEARS OR OLDER: UNITED STATES, 2014

1. **Additional information**
   - Additional guidance for the use of the vaccines described in this supplement is available at www.cdc.gov/vaccines/hcp/acip-recs/index.html.
   - Information on vaccination recommendations when vaccination status is unknown and other general immunization information can be found in the General Recommendations on Immunization at www.cdc.gov/mmwr/preview/mmwrhtml/rr6002a1.htm.
   - Information on travel vaccine requirements and recommendations (e.g., for hepatitis A and B, meningococcal, and other vaccines) is available at http://wwwnc.cdc.gov/travel/destinations/list.
   - Additional information and resources regarding vaccination of pregnant women can be found at http://wwwnc.cdc.gov/travel/destinations/list.
2. **Influenza vaccination**
   - Annual vaccination against influenza is recommended for all persons aged 6 months or older.
   - Persons aged 6 months or older, including pregnant women and persons with hives-only allergy to eggs, can receive the inactivated influenza vaccine (IIV). An age-appropriate IIV formulation should be used.
   - Adults aged 18 to 49 years can receive the recombinant influenza vaccine (RIV) (FluBlok). RIV does not contain any egg protein.
   - Healthy, nonpregnant persons aged 2 to 49 years without high-risk medical conditions can receive either intranasally administered live, attenuated influenza vaccine (LAIV) (FluMist), or IIV. Health care personnel who care for severely immunocompromised persons (i.e., those who require care in a protected environment) should receive IIV or RIV rather than LAIV.
   - The intramuscularly or intradermally administered IIV are options for adults aged 18 to 64 years.
   - Adults aged 65 years or older can receive the standard-dose IIV or the high-dose IIV (Fluzone High-Dose).
3. **Tetanus, diphtheria, and acellular pertussis (Td/Tdap) vaccination**
   - Administer 1 dose of Tdap vaccine to pregnant women during each pregnancy (preferred during 27 to 36 weeks' gestation) regardless of interval since prior Td or Tdap vaccination.
   - Persons aged 11 years or older who have not received Tdap vaccine or for whom vaccine status is unknown should receive a dose of Tdap followed by tetanus and diphtheria toxoids (Td) booster doses every 10 years thereafter. Tdap can be administered regardless of interval since the most recent tetanus or diphtheria-toxoid containing vaccine.
   - Adults with an unknown or incomplete history of completing a 3-dose primary vaccination series with Td-containing vaccines should begin or complete a primary vaccination series including a Tdap dose.
   - For unvaccinated adults, administer the first 2 doses at least 4 weeks apart and the third dose 6 to 12 months after the second.
   - For incompletely vaccinated (i.e., less than 3 doses) adults, administer remaining doses.
   - Refer to the ACIP statement for recommendations for administering Td/ Tdap as prophylaxis in wound management (see footnote 1).
4. **Varicella vaccination**
   - All adults without evidence of immunity to varicella (as defined below) should receive 2 doses of single-antigen varicella vaccine or a second dose if they have received only 1 dose.
   - Vaccination should be emphasized for those who have close contact with persons at high risk for severe disease (e.g., health care personnel and family contacts of persons with immunocompromising conditions) or are at high risk for exposure or transmission (e.g., teachers; child care employees; residents and staff members of institutional settings, including correctional institutions; college students; military personnel; adolescents and adults living in households with children; nonpregnant women of childbearing age; and international travelers).
   - Pregnant women should be assessed for evidence of varicella immunity. Women who do not have evidence of immunity should receive the first dose of varicella vaccine upon completion or termination of pregnancy and before discharge from the health care facility. The second dose should be administered 4 to 8 weeks after the first dose.
   - Evidence of immunity to varicella in adults includes any of the following:
     - documentation of 2 doses of varicella vaccine at least 4 weeks apart;
     - U.S.-born before 1980, except health care personnel and pregnant women;
     - history of varicella based on diagnosis or verification of varicella disease by a health care provider;
     - history of herpes zoster based on diagnosis or verification of herpes zoster disease by a health care provider; or
     - laboratory evidence of immunity or laboratory confirmation of disease.
5. **Human papillomavirus (HPV) vaccination**
   - Two vaccines are licensed for use in females, bivalent HPV vaccine (HPV2) and quadrivalent HPV vaccine (HPV4), and one HPV vaccine for use in males (HPV4).
   - For females, either HPV4 or HPV2 is recommended in a 3-dose series for routine vaccination at age 11 or 12 years and for those aged 13 through 26 years, if not previously vaccinated.
   - For males, HPV4 is recommended in a 3-dose series for routine vaccination at age 11 or 12 years and for those aged 13 through 21 years, if not previously vaccinated. Males aged 22 through 26 years may be vaccinated.
   - HPV4 is recommended for men who have sex with men through age 26 years for those who did not get any or all doses when they were younger.
   - Vaccination is recommended for immunocompromised persons (including those with HIV infection) through age 26 years for those who did not get any or all doses when they were younger.
   - A complete series for either HPV4 or HPV2 consists of 3 doses. The second dose should be administered 4 to 8 weeks (minimum interval of 4 weeks) after the first dose; thethird dose should be administered 24 weeks after the first dose and 16 weeks after the second dose (minimum interval of at least 12 weeks).
   - HPV vaccines are not recommended for use in pregnant women. However, pregnancy testing is not needed before vaccination. If a woman is found to be pregnant after initiating the vaccination series, no intervention is needed; the remainder of the 3-dose series should be delayed until completion of pregnancy.
6. **Zoster vaccination**
   - A single dose of zoster vaccine is recommended for adults aged 60 years or older regardless of whether they report a prior episode of herpes zoster. Although the vaccine is licensed by the U.S. Food and Drug Administration for use among and can be administered to persons aged 50 years or older, ACIP recommends that vaccination begin at age 60 years.
   - Persons aged 60 years or older with chronic medical conditions may be vaccinated unless their condition constitutes a contraindication, such as pregnancy or severe immunodeficiency.

E-TABLE 18-1 FOOTNOTES RECOMMENDED IMMUNIZATION SCHEDULE FOR ADULTS AGED 19 YEARS OR OLDER: UNITED STATES, 2014—cont'd

7. **Measles, mumps, rubella (MMR) vaccination**
   - Adults born before 1957 are generally considered immune to measles and mumps. All adults born in 1957 or later should have documentation of 1 or more doses of MMR vaccine unless they have a medical contraindication to the vaccine or laboratory evidence of immunity to each of the three diseases. Documentation of provider-diagnosed disease is not considered acceptable evidence of immunity for measles, mumps, or rubella.

   Measles component:
   - A routine second dose of MMR vaccine, administered a minimum of 28 days after the first dose, is recommended for adults who:
     - — are students in postsecondary educational institutions;
     - — work in a health care facility; or
     - — plan to travel internationally.
   - Persons who received inactivated (killed) measles vaccine or measles vaccine of unknown type during 1963-1967 should be revaccinated with 2 doses of MMR vaccine.

   Mumps component:
   - A routine second dose of MMR vaccine, administered a minimum of 28 days after the first dose, is recommended for adults who:
     - — are students in a postsecondary educational institution;
     - — work in a health care facility; or
     - — plan to travel internationally.
   - Persons vaccinated before 1979 with either killed mumps vaccine or mumps vaccine of unknown type who are at high risk for mumps infection (e.g., persons who are working in a health care facility) should be considered for revaccination with 2 doses of MMR vaccine.

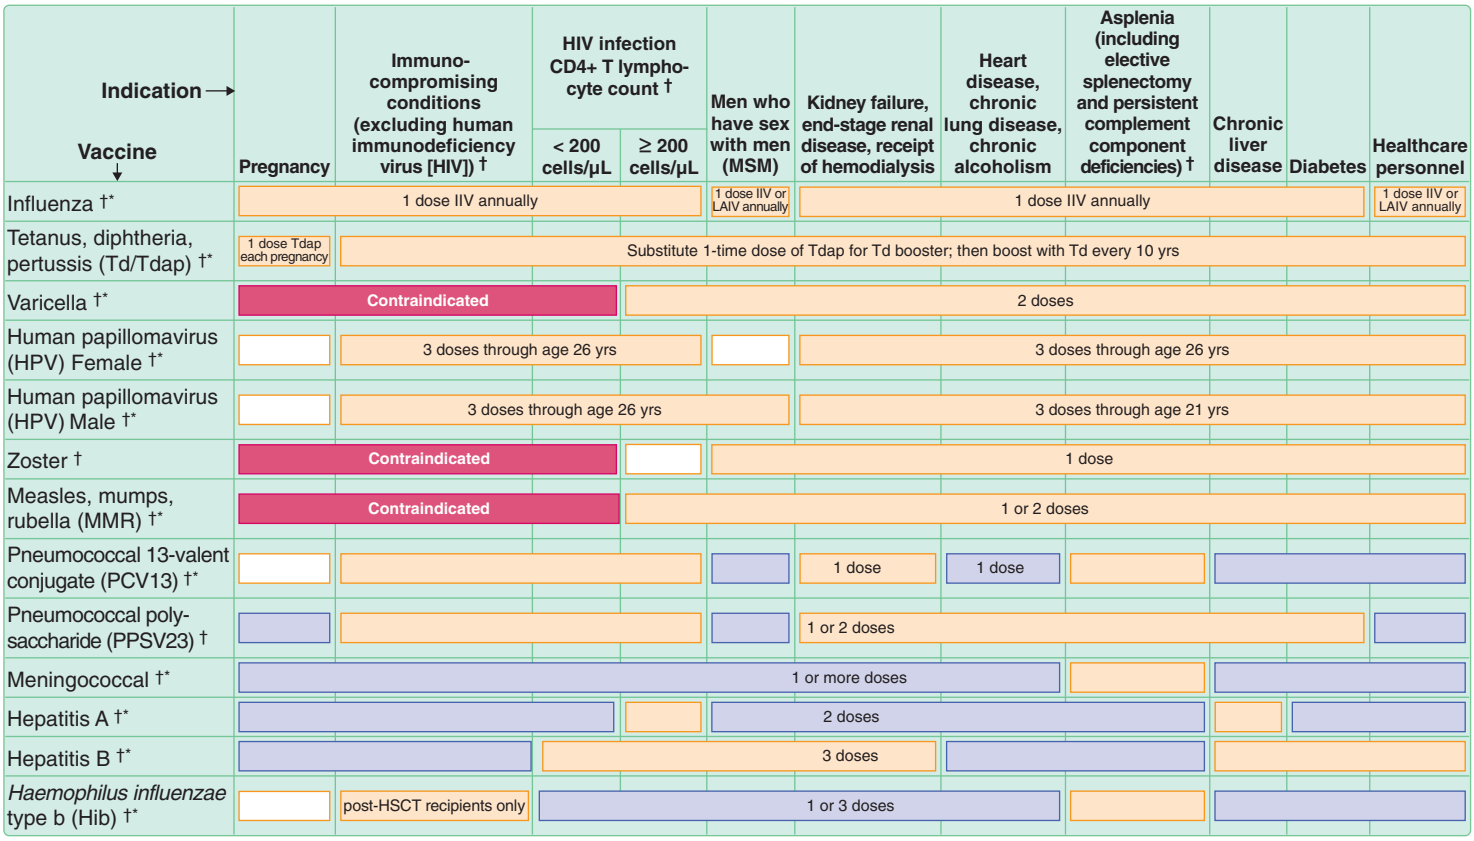
   Rubella component:
   - For women of childbearing age, regardless of birth year, rubella immunity should be determined. If there is no evidence of immunity, women who are not pregnant should be vaccinated. Pregnant women who do not have evidence of immunity should receive MMR vaccine upon completion or termination of pregnancy and before discharge from the health care facility.

   Health care personnel born before 1957:
   - For unvaccinated health care personnel born before 1957 who lack laboratory evidence of measles, mumps, and/or rubella immunity or laboratory confirmation of disease, health care facilities should consider vaccinating personnel with 2 doses of MMR vaccine at the appropriate interval for measles and mumps or 1 dose of MMR vaccine for rubella.
8. **Pneumococcal conjugate (PCV13) vaccination**
   - Adults aged 19 years or older with immunocompromising conditions (including chronic renal failure and nephrotic syndrome), functional or anatomic asplenia, cerebrospinal fluid leaks, or cochlear implants who have not previously received PCV13 or PPSV23 should receive a single dose of PCV13 followed by a dose of PPSV23 at least 8 weeks later.
   - Adults aged 19 years or older with the aforementioned conditions who have previously received 1 or more doses of PPSV23 should receive a dose of PCV13 one or more years after the last PPSV23 dose was received. For adults who require additional doses of PPSV23, the first such dose should be given no sooner than 8 weeks after PCV13 and at least 5 years after the most recent dose of PPSV23.
   - When indicated, PCV13 should be administered to patients who are uncertain of their vaccination status history and have no record of previous vaccination.
   - Although PCV13 is licensed by the U.S. Food and Drug Administration for use among and can be administered to persons aged 50 years or older, ACIP recommends PCV13 for adults aged 19 years or older with the specific medical conditions noted above.
9. **Pneumococcal polysaccharide (PPSV23) vaccination**
   - When PCV13 is also indicated, PCV13 should be given first (see footnote 8).
   - Vaccinate all persons with the following indications:
     - — all adults aged 65 years or older;
     - — adults younger than 65 years with chronic lung disease (including chronic obstructive pulmonary disease, emphysema, and asthma), chronic cardiovascular diseases, diabetes mellitus, chronic renal failure, nephrotic syndrome, chronic liver disease (including cirrhosis), alcoholism, cochlear implants, cerebrospinal fluid leaks, immunocompromising conditions, and functional or anatomic asplenia (e.g., sickle cell disease and other hemoglobinopathies, congenital or acquired asplenia, splenic dysfunction, or splenectomy [if elective splenectomy is planned, vaccinate at least 2 weeks before surgery]);
     - — residents of nursing homes or long-term care facilities; and
     - — adults who smoke cigarettes.
   - Persons with immunocompromising conditions and other selected conditions are recommended to receive PCV13 and PPSV23 vaccines. See footnote 8 for information on timing of PCV13 and PPSV23 vaccinations.
   - Persons with asymptomatic or symptomatic HIV infection should be vaccinated as soon as possible after their diagnosis.
   - When cancer chemotherapy or other immunosuppressive therapy is being considered, the interval between vaccination and initiation of immunosuppressive therapy should be at least 2 weeks. Vaccination during chemotherapy or radiation therapy should be avoided.
   - Routine use of PPSV23 vaccine is not recommended for American Indians/Alaska Natives or other persons younger than 65 years unless they have underlying medical conditions that are PPSV23 indications. However, public health authorities may consider recommending PPSV23 for American Indians/Alaska Natives who are living in areas where the risk for invasive pneumococcal disease is increased.
   - When indicated, PPSV23 vaccine should be administered to patients who are uncertain of their vaccination status and have no record of vaccination.
10. **Revaccination with PPSV23**
    - One-time revaccination 5 years after the first dose of PPSV23 is recommended for persons aged 19 through 64 years with chronic renal failure or nephrotic syndrome, functional or anatomic asplenia (e.g., sickle cell disease or splenectomy), or immunocompromising conditions.
    - Persons who received 1 or 2 doses of PPSV23 before age 65 years for any indication should receive another dose of the vaccine at age 65 years or later if at least 5 years have passed since their previous dose.
    - No further doses of PPSV23 are needed for persons vaccinated with PPSV23 at or after age 65 years.
11. **Meningococcal vaccination**
    - Administer 2 doses of quadrivalent meningococcal conjugate vaccine (MenACWY-D [Menactra]) at least 2 months apart to adults of all ages with functional asplenia or persistent complement component deficiencies. HIV infection is not an indication for routine vaccination with MenACWY-D. If an HIV-infected person of any age is vaccinated, 2 doses of MenACWY-D should be administered at least 2 months apart.
    - Administer a single dose of meningococcal vaccine to microbiologists routinely exposed to isolates of Neisseria meningitidis, military recruits, persons at risk during an outbreak attributable to a vaccine serogroup, and persons who travel to or live in countries in which meningococcal disease is hyperendemic or epidemic.
    - First-year college students up through age 21 years who are living in residence halls should be vaccinated if they have not received a dose on or after their 16th birthday.
    - MenACWY-D is preferred for adults with any of the preceding indications who are aged 55 years or younger as well as for adults aged 56 years or older who a) were vaccinated previously with MenACWY-D and are recommended for revaccination, or b) for whom multiple doses are anticipated. Meningococcal polysaccharide vaccine (MenACWY-CRM [Menveo]) is preferred for adults aged 56 years or older who have not received MenACWY-D previously and who require a single dose only (e.g., travelers).
    - Revaccination with MenACWY-D every 5 years is recommended for adults previously vaccinated with MenACWY-D or MenACWY-CRM who remain at increased risk for infection (e.g., adults with anatomic or functional asplenia, persistent complement component deficiencies, or microbiologists).

E-TABLE 18-1 FOOTNOTES RECOMMENDED IMMUNIZATION SCHEDULE FOR ADULTS AGED 19 YEARS OR OLDER: UNITED STATES, 2014—cont'd

12. **Hepatitis A vaccination**
    - Vaccinate any person seeking protection from hepatitis A virus (HAV) infection and persons with any of the following indications:
        - men who have sex with men and persons who use injection or noninjection illicit drugs;
        - persons working with HAV-infected primates or with HAV in a research laboratory setting;
        - persons with chronic liver disease and persons who receive clotting factor concentrates;
        - persons traveling to or working in countries that have high or intermediate endemicity of hepatitis A; and
        - unvaccinated persons who anticipate close personal contact (e.g., household or regular babysitting) with an international adoptee during the first 60 days after arrival in the United States from a country with high or intermediate endemicity. (See footnote 1 for more information on travel recommendations.) The first dose of the 2-dose hepatitis A vaccine series should be administered as soon as adoption is planned, ideally 2 or more weeks before the arrival of the adoptee.
    - Single-antigen vaccine formulations should be administered in a 2-dose schedule at either 0 and 6 to 12 months (Havrix), or 0 and 6 to 18 months (Vaqta). If the combined hepatitis A and hepatitis B vaccine (Twinrix) is used, administer 3 doses at 0, 1, and 6 months; alternatively, a 4-dose schedule may be used, administered on days 0, 7, and 21 to 30 followed by a booster dose at month 12.
13. **Hepatitis B vaccination**
    - Vaccinate persons with any of the following indications and any person seeking protection from hepatitis B virus (HBV) infection:
        - sexually active persons who are not in a long-term, mutually monogamous relationship (e.g., persons with more than 1 sex partner during the previous 6 months); persons seeking evaluation or treatment for a sexually transmitted disease (STD); current or recent injection drug users; and men who have sex with men;
        - health care personnel and public safety workers who are potentially exposed to blood or other infectious body fluids;
        - persons with diabetes who are younger than age 60 years as soon as feasible after diagnosis; persons with diabetes who are age 60 years or older at the discretion of the treating clinician based on the likelihood of acquiring HBV infection, including the risk posed by an increased need for assisted blood glucose monitoring in long-term care facilities, the likelihood of experiencing chronic sequelae if infected with HBV, and the likelihood of immune response to vaccination;
        - persons with end-stage renal disease, including patients receiving hemodialysis, persons with HIV infection, and persons with chronic liver disease;
        - household contacts and sex partners of hepatitis B surface antigen-positive persons, clients and staff members of institutions for persons with developmental disabilities, and international travelers to countries with high or intermediate prevalence of chronic HBV infection; and
        - all adults in the following settings: STD treatment facilities, HIV testing and treatment facilities, facilities providing drug abuse treatment and prevention services, health care settings targeting services to injection drug users or men who have sex with men, correctional facilities, end-stage renal disease programs and facilities for chronic hemodialysis patients, and institutions and nonresidential day care facilities for persons with developmental disabilities.
    - Administer missing doses to complete a 3-dose series of hepatitis B vaccine to those persons not vaccinated or not completely vaccinated. The second dose should be administered 1 month after the first dose; the third dose should be given at least 2 months after the second dose (and at least 4 months after the first dose). If the combined hepatitis A and hepatitis B vaccine (Twinrix) is used, give 3 doses at 0, 1, and 6 months; alternatively, a 4-dose Twinrix schedule, administered on days 0, 7, and 21 to 30 followed by a booster dose at month 12 may be used.
    - Adult patients receiving hemodialysis or with other immunocompromising conditions should receive 1 dose of 40 mcg/mL (Recombivax HB) administered on a 3-dose schedule at 0, 1, and 6 months or 2 doses of 20 mcg/mL (Engerix-B) administered simultaneously on a 4-dose schedule at 0, 1, 2, and 6 months.
14. ***Haemophilus influenzae type b* (Hib) vaccination**
    - One dose of Hib vaccine should be administered to persons who have functional or anatomic asplenia or sickle cell disease or are undergoing elective splenectomy if they have not previously received Hib vaccine. Hib vaccination 14 or more days before splenectomy is suggested.
    - Recipients of a hematopoietic stem cell transplant should be vaccinated with a 3-dose regimen 6 to 12 months after a successful transplant, regardless of vaccination history; at least 4 weeks should separate doses.
    - Hib vaccine is not recommended for adults with HIV infection since their risk for Hib infection is low.
15. **Immunocompromising conditions**
    - Inactivated vaccines generally are acceptable (e.g., pneumococcal, meningococcal, and inactivated influenza vaccine) and live vaccines generally are avoided in persons with immune deficiencies or immunocompromising conditions. Information on specific conditions is available at http://www.cdc.gov/vaccines/hcp/acip-recs/index.html.

Vaccines That Might Be Indicated for Adults Based on Medical and Other Indications†



*Covered by the Vaccine Injury Compensation Program †For additional information please see http://www.cdc.gov/vaccines/schedules/downloads/adult/adult-schedule.pdf

These schedules indicate the recommended age groups and medical indications for which administration of currently licensed vaccines is commonly indicated for adults ages 19 years and older, as of Febuary 1, 2014. For all vaccines being recommended on the Adult Immunization Schedule: a vaccine series does not need to be restarted, regardless of the time that has elapsed between doses. Licensed combination vaccines may be used whenever any components of the combination are indicated and when the vaccine's other components are not contraindicated. For detailed recommendations on all vaccines, including those used primarily for travelers or that are issued during the year, consult the manufacturers' package inserts and the complete statements from the Advisory Committee on Immunization Practices (www.cdc.gov/vaccines/hcp/acip-recs/index.html). Use of trade names and commerical sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

FIGURE 18-2. Recommended adult immunization schedule by vaccine and medical and other indications, United States, 2014. See E-Table 18-1 for footnotes. (Adapted from http://www.cdc.gov/vaccines/schedules/downloads/adult/adult-combined-schedule.pdf.)

TABLE 18-2 SELECTED IMMUNIZING AGENTS INDICATED FOR ADULTS*

DISEASE	IMMUNIZING AGENT	INDICATIONS	SCHEDULE	MAJOR CONTRAINDICATIONS AND PRECAUTIONS	COMMENTS
Anthrax	Anthrax vaccine, adsorbed, an inactivated vaccine	Pre-exposure prophylaxis of persons at high risk of exposure (e.g., military, certain laboratory workers) Consider with antibiotics for postexposure prophylaxis	0.5-mL dose IM at 0, 4, and 6 wk and boosters at 12 and 18 mo, then booster annually thereafter If used after exposure, three doses at 0, 2, and 4 wk with 60 days of antimicrobial therapy; antibiotics should be continued for 14 days after third dose	Severe allergic reaction to a vaccine component or after a prior dose Moderate or severe acute illness is a precaution to vaccination	Effectiveness against aerosol exposure inferred primarily from animal data Limited data on the benefits of postexposure use
Diphtheria	Tetanus and diphtheria toxoids combined	All adults	For incompletely immunized adults, three doses IM needed for primary series: two doses IM 4 wk apart, third dose 6-12 mo after second dose; one of these doses should be Tdap Booster every 10 yr No need to repeat if schedule is interrupted	History of neurologic reaction after a previous dose Severe allergic reaction to a vaccine component or after a prior dose	Tetanus and diphtheria toxoids combined with acellular pertussis vaccine (Tdap) preferred as one-time booster for all persons Moderate or severe acute illness is a precaution

TABLE 18-2 SELECTED IMMUNIZING AGENTS INDICATED FOR ADULTS—cont'd

DISEASE	IMMUNIZING AGENT	INDICATIONS	SCHEDULE	MAJOR CONTRAINDICATIONS AND PRECAUTIONS	COMMENTS
Hepatitis A	Inactivated hepatitis A vaccine	Travelers to highly or intermediately endemic countries Men who have sex with men Illegal drug users (injection and noninjection) Persons who work with hepatitis A virus–infected primates or who do research with the virus Persons with chronic liver disease Recipients of clotting factors	Two doses at least 6 mo apart for persons aged ≥1 yr	Severe allergic reaction to a vaccine component or after a prior dose Moderate or severe acute illness is a precaution to vaccination	Recommended for all children Should be considered for outbreak control
Hepatitis B	Inactivated hepatitis B virus subunit vaccine containing HBsAg	Adolescents Health care and public safety workers potentially exposed to blood Clients and staff of institutions for the developmentally disabled Hemodialysis patients Men who have sex with men Users of illicit injectable drugs Recipients of clotting factors Household and sexual contacts of HBV carriers Inmates of long-term correctional facilities Heterosexuals treated for sexually transmitted diseases or with multiple sexual partners Travelers with close contact for ≥6 mo with populations with high prevalence of HBV carriage Adults 19-59 yr with diabetes mellitus	Three doses IM at 0, 1, and 6 mo	Severe allergic reaction to a vaccine component or after a prior dose Moderate or severe acute illness is a precaution to vaccination	Pregnancy is not a contraindication. Health care workers who have contact with patients or blood, sexual contacts of persons with chronic HBV infection, hemodialysis patients, other immunosuppressed persons, and recipients of clotting factor concentrates should be tested 1-2 mo after vaccination to determine serologic response.
Human papillomavirus	Inactivated L1 capsid proteins of types 6, 11, 16, and 18 (quadrivalent) and types 16 and 18 (bivalent)	Females at 11-12 yr; catch-up vaccination of females through 26 yr Males 11-12 yr (quadrivalent vaccine only) and catch-up vaccination through 21 yr; consider catch-up through 26 yr to prevent anogenital and oropharyngeal cancers and genital warts	Three 0.5-mL doses IM at 0, 1 to 2, and 6 mo	Severe allergic reaction to a vaccine component or to a prior dose Vaccine is not recommended for pregnant women	The vaccine will not protect against existing infections. Because the types in the vaccine are not responsible for about 30% of infections associated with cervical cancer, screening for cancer should occur as for unvaccinated women.
Influenza	Inactivated virus vaccine	All persons ≥6 months of age, with greatest priority for those at higher risk for influenza complications (e.g., ≥65 yr old, persons with underlying medical conditions, pregnant women) or in contact with those at higher risk (e.g., health care workers, and persons with close contact with children <5 yr)	Annual vaccination; see annual ACIP recommendation	Severe allergic reaction to an influenza vaccine component (including eggs) or after a prior dose Recombinant vaccine (RIV) containing no egg protein may be given to persons 18-49 yr with severe egg allergies Moderate or severe acute illness is a precaution to vaccination GBS within 6 wk of prior dose of influenza vaccine	Optimum timing for vaccination is October. However, vaccination can occur throughout the influenza season, particularly for persons at high risk for complications and their contacts who were not vaccinated earlier. Only one dose of influenza vaccine per season is recommended for adults.

TABLE 18-2 SELECTED IMMUNIZING AGENTS INDICATED FOR ADULTS—cont'd

DISEASE	IMMUNIZING AGENT	INDICATIONS	SCHEDULE	MAJOR CONTRAINDICATIONS AND PRECAUTIONS	COMMENTS
Influenza (cont'd)	Live attenuated influenza virus	Persons 2 through 49 yr without underlying conditions that place them at high risk of complications from influenza	Annual vaccination; see annual ACIP statement Administered intranasally	Persons <2 yr or ≥50 yr Persons with underlying disorders that place them at high risk of influenza complications History of GBS within 6 wk of prior dose of influenza vaccine Pregnant women Hypersensitivity to eggs or components of vaccine	Can be used for household contacts and health care workers caring for patients without severe immunocompromise
Japanese encephalitis	Inactivated Japanese encephalitis virus vaccine	Travelers to Asia spending at least 1 mo in endemic areas during transmission season	Two 0.5-mL doses IM on days 0 and 28 for persons 18 yr and older	Pregnancy	
Measles	Live virus vaccine	All adults born after 1956 without history of live vaccine on or after first birthday or detectable measles antibody Persons born before 1957 generally can be considered immune	One dose sufficient for most adults; two doses at least 1 mo apart indicated for persons entering college or medical facility employment, traveling abroad, or at risk of measles during outbreaks	Altered immunity (e.g., leukemia, lymphoma, generalized malignant disease, congenital immunodeficiency, immunosuppressive therapy) Immune globulin or other blood products within prior 3-11 mo, depending on dose of immune globulin or blood product received Untreated tuberculosis Anaphylactic hypersensitivity to neomycin or gelatin Pregnancy Thrombocytopenia	Persons with anaphylactic allergies to eggs may be vaccinated (see text). Vaccine should be administered to persons with asymptomatic HIV infection and should be considered for patients except those with severe immunocompromise.
Meningococcal disease (two vaccines)	1. Meningococcal conjugate vaccines containing polysaccharide of serogroups A, C, W, and Y (age 2 mo–55 yr) 2. Polysaccharide vaccine containing tetravalent A, C, W, and Y (ages 56 yr and older, if never vaccinated and only one vaccination expected to be necessary)	All 11- to 18-yr-old persons and all persons with persistent complement component deficiencies or anatomic or functional asplenia Persons who will travel to areas with hyperendemic or epidemic diseases Certain laboratory workers May be useful during localized outbreaks	One dose with revaccination at age 16 yr of children who receive conjugate vaccine at 11-12 yr of age and every 5 yr for persons at high risk	Allergic reactions to a component of the vaccine, including diphtheria toxoid and latex	Conjugate vaccine is preferred to polysaccharide alone for persons aged 2 mo through 55 yr and for persons 56 yr and older previously vaccinated who continue to be at risk.
Mumps	Live virus vaccine	All adults born after 1956 without history of live vaccine on or after first birthday or detectable mumps antibody Persons born before 1957 generally can be considered immune	One dose sufficient for most adults Two doses at least 1 mo apart indicated for persons entering college or medical facility employment or traveling abroad	Altered immunity (e.g., leukemia, lymphoma, generalized malignant disease, congenital immunodeficiency, immunosuppressive therapy) Immune globulin or other blood products within prior 3-11 mo Anaphylactic hypersensitivity to neomycin or gelatin Pregnancy Thrombocytopenia if administered with measles vaccine	Although persons born after 1956 are generally immune, vaccine can be given to adults of all ages and may be particularly indicated for postpubertal males who are thought to be susceptible. Persons with anaphylactic allergies to eggs may be vaccinated.

TABLE 18-2 SELECTED IMMUNIZING AGENTS INDICATED FOR ADULTS—cont'd

DISEASE	IMMUNIZING AGENT	INDICATIONS	SCHEDULE	MAJOR CONTRAINDICATIONS AND PRECAUTIONS	COMMENTS
Pertussis	Adult preparation of pertussis antigens combined with tetanus and diphtheria toxoids (Tdap)	All 11- to 12-yr-olds Catch-up vaccination for all persons ≥13 yr	One dose Pregnant women: one dose during each pregnancy between 27 and 36 weeks of gestation	Severe allergic reaction to a vaccine component or after a prior dose Moderate or severe acute illness is a precaution to vaccination	Two preparations are available, one licensed for all persons ≥10 yr, one for 10- to 64-yr-olds.
Pneumococcal disease	23-Valent polysaccharide vaccine (PPSV23)	All adults with cardiovascular disease, pulmonary disease (including asthma), diabetes mellitus, alcoholism, cirrhosis, cerebrospinal fluid leaks, splenic dysfunction or anatomic asplenia, Hodgkin disease, lymphoma, multiple myeloma, chronic renal failure, nephrotic syndrome, immunosuppression, HIV infection, cigarette smokers 19 yr and older High-risk populations, such as certain Native Americans, and All adults ≥65 yr	One dose IM or SC; a second dose should be considered ≥5 yr later for adults at high risk of disease (e.g., asplenic patients) and those who lose antibody rapidly (e.g., nephrotic syndrome, renal failure, transplant recipients) Revaccinate adults who received a first dose when <65 yr who are now ≥65 yr and who received their vaccine at least 5 yr earlier	Severe allergic reaction to a vaccine component or after a prior dose Moderate or severe acute illness is a precaution to vaccination	
	Pneumococcal conjugate vaccine (PCV13)	One dose recommended for all adults age 65 years and older, for immunocompromised adults ≥19 yr, and those with functional/anatomic asplenia, cochlear implants, cerebrospinal fluid leaks	One dose if not previously vaccinated with PCV13) as an adult Give ≥1 year after PPSV23; or if PPSV23-naïve, if 65 years or older and not immunocompromised, give PPSV23 6-12 months after PCV13; if >19 yrs old and immunocompromised, give PPSV23 ≥8 wk after PCV13	Severe allergic reaction (e.g., anaphylaxis) to any component of PCV13 or any diphtheria toxoid-containing vaccine Moderate or severe acute illness is a precaution to vaccination	Although licensed for use in adults ≥50 yr, it is recommended only for adults ≥19 yr with the noted medical conditions.
Poliomyelitis	Inactivated poliovirus vaccine (IPV)	Certain adults who are at greater risk of exposure to wild poliovirus than the general population, including travelers to countries where poliomyelitis is epidemic or endemic or specific populations with disease caused by wild poliovirus	For unvaccinated adults, two doses IM or SC 4 wk apart and a third dose 6-12 mo after the second; if <4 wk available before protection is needed, a single dose of IPV For incompletely immunized adults, complete primary series of three doses of IPV or prior oral poliovirus vaccine (OPV); no need to restart interrupted series A single dose of IPV can be given to adults who previously received a primary series but now are at high risk, such as those traveling to an endemic area	On theoretical grounds, pregnant women should not receive IPV, but if immediate protection is needed, IPV can be used Severe allergic reaction to a vaccine component or after a prior dose Moderate or severe acute illness is a precaution to vaccination	
Rabies	Inactivated vaccine, HDCV or PCEC	High-risk persons, including animal handlers, selected laboratory and field workers, and persons traveling for ≥1 mo to areas with high risk of rabies	Pre-exposure prophylaxis: three doses of 1 mL IM on days 0, 7, and 21 or 28	History of severe hypersensitivity reaction	Further doses needed after exposure

TABLE 18-2 SELECTED IMMUNIZING AGENTS INDICATED FOR ADULTS—cont'd

DISEASE	IMMUNIZING AGENT	INDICATIONS	SCHEDULE	MAJOR CONTRAINDICATIONS AND PRECAUTIONS	COMMENTS
Rubella	Live virus vaccine	Adults, particularly women of childbearing age, who lack history of rubella vaccine and detectable rubella-specific antibodies in serum Males and females in institutions where rubella outbreaks may occur, such as hospitals, the military, and colleges Persons born before 1957, except women who can become pregnant, generally can be considered immune	One dose SC	Pregnancy, altered immunity (e.g., leukemia, lymphoma, generalized malignant disease, congenital immunodeficiency, immunosuppressive therapy) Immune globulin or other blood products within 3-11 mo before vaccination Anaphylactic hypersensitivity to neomycin Administration of blood products should not contraindicate postpartum vaccination Thrombocytopenia if administered with measles vaccine	Women should be counseled to avoid pregnancy for 1 mo after vaccination.
Smallpox	Live vaccinia virus	Persons working with orthopox viruses Members of public health and health care response teams	One dose intracutaneously with a bifurcated needle Boosters every 10 yr and perhaps every 3 yr for persons working with virulent orthopox viruses	History or presence of eczema or other acute, chronic, or exfoliative skin condition in patient or a close household or personal contact Immunosuppression or pregnancy in patient or a close household or personal contact History of heart disease Breast-feeding Age <1 yr Allergy to a vaccine component No contraindications if exposed to smallpox	Some complications of vaccination are treatable with vaccinia immune globulin. Vaccine is effective 3-4 days after exposure to variola and perhaps longer to prevent or to modify the illness. Serious adverse events are rare but significant, including eczema vaccinatum, progressive vaccinia, myopericarditis, autoinoculation, and encephalitis. Vaccinia is transmissible.
Tetanus	Tetanus and diphtheria toxoids combined	All adults	Three doses IM needed for primary series: two doses 4 wk apart, third dose 6-12 mo after second dose Booster every 10 yr; no need to repeat if schedule is interrupted	History of neurologic or severe allergic reaction after a prior dose	Special recommendations for wound treatment (see text) Persons with GBS within the first 6 wk after immunization, particularly adults who received a prior primary series, probably should not be revaccinated in most circumstances. Tetanus and diphtheria toxoids combined with acellular pertussis (Tdap) vaccine preferred for booster at age 11-12 yr One-time booster of Tdap for all adults
Typhoid fever	Vi capsular polysaccharide vaccine Live attenuated Ty21a oral vaccine	Travelers to areas where the risk of prolonged exposure to contaminated food and water is high May be considered for family and intimate contacts of carriers and laboratory workers who work with *Salmonella typhi*	Vi polysaccharide vaccine: one dose IM 0.5 mL; boosters every 2 yr Oral vaccine: four doses on alternate days; repeat series every 5 yr if risk continues	Severe local or systemic reaction to a prior dose Ty21a vaccine should not be administered to persons with altered immunity or those receiving antimicrobial agents	Efficacy only 50-77% Food and water precautions essential

TABLE 18-2 SELECTED IMMUNIZING AGENTS INDICATED FOR ADULTS—cont'd

DISEASE	IMMUNIZING AGENT	INDICATIONS	SCHEDULE	MAJOR CONTRAINDICATIONS AND PRECAUTIONS	COMMENTS
Varicella: chickenpox strain	Attenuated Oka strain of varicella virus	All persons without evidence of varicella immunity, especially health care personnel, childbearing-age women, and persons with household or other contact with persons at high risk of complications of varicella (e.g., susceptible immunosuppressed persons)	Two 0.5-mL doses SC 4-8 wk apart for persons ≥13 yr A second dose is recommended for all persons who previously received one dose	Immunocompromise Pregnancy Allergy to vaccine components	Adults with a history of prior clinician-diagnosed or verified varicella can be considered immune. Vaccine virus has rarely been transmitted to contacts from healthy vaccinees in whom rash developed. Women who receive vaccine should not become pregnant for 1 mo.
Varicella: zoster	Attenuated Oka strain of varicella virus, approximately 14 times more potent than varicella vaccine	Persons ≥60 years of age	One 0.65-mL dose SC	Immunocompromise Pregnancy Allergy to vaccine components	May be administered regardless of a prior history of shingles
Yellow fever	Live attenuated virus (17D strain)	Persons living or traveling in areas where yellow fever exists	One dose; booster every 10 yr	Immunocompromised persons History of anaphylactic allergies to eggs Pregnancy on theoretical grounds, although may be given if risk is high	Fever, jaundice, and multiple-organ system failure (viscerotropic disease) have been rarely reported in first-time recipients of 17D-derived yellow fever vaccinations. Vaccinate only persons traveling to areas endemic to yellow fever.

*See the text and package inserts for further details, particularly regarding indications, dosage, administration, side effects, and adverse reactions and contraindications.
ACIP = Advisory Committee on Immunization Practices; GBS = Guillain-Barré syndrome; HBsAg = hepatitis B surface antigen; HBV = hepatitis B virus; HDCV = human diploid cell vaccine for rabies; HIV = human immunodeficiency virus; IM = intramuscularly; IPV = inactivated poliovirus vaccine; MMR = measles, mumps, and rubella vaccine; OPV = live trivalent oral poliovirus vaccine; PCEC = purified chick embryo cell culture rabies vaccine; SC = subcutaneously.

Immunocompromised Persons

Patients with conditions that compromise their immune systems—immunodeficiency diseases, leukemia, lymphoma, and generalized malignant disease, and those who are immunosuppressed from therapy with corticosteroids, alkylating agents, antimetabolites, and radiation—generally should not receive live attenuated vaccines. An exception is infection with human immunodeficiency virus (HIV). Two doses of MMR vaccine are recommended for all persons aged 12 months and older who have HIV infection and do not have evidence of immunity to measles, rubella, and mumps and who are not severely immunosuppressed (i.e., a CD4 percentage ≥15% and $CD4^+$ lymphocyte counts ≥200 cells/μL for ≥6 months for persons aged >5 years). Varicella vaccination (two doses, 3 months apart) may be considered in HIV-infected persons with $CD4^+$ T-lymphocyte counts above 200 cells/μL. Patients with leukemia in remission who have not been receiving any chemotherapy for at least 3 months may receive live virus vaccines. Short-course therapy (<2 weeks) with corticosteroids, alternate-day regimens with low to moderate doses of short-acting corticosteroids, and topical applications or tendon injections are not ordinarily contraindications to the administration of live vaccines.

Immunocompromised patients can receive inactivated vaccines and toxoids, although the efficacy of such preparations may be diminished. Patients with known HIV infection should receive pneumococcal vaccine and annual influenza vaccination.

Pregnancy

In general, live vaccines should not be given to pregnant women because of the theoretical concern that the vaccines could adversely affect the fetus. No significant adverse events have been documented as attributable to vaccination of pregnant women with rubella-containing or varicella vaccines; nevertheless, pregnant women should not receive MMR or varicella vaccine, and women who do receive these vaccines should wait 1 month before becoming pregnant. Poliomyelitis and yellow fever vaccines usually should not be given to pregnant women unless the risk of disease is substantial. Tdap vaccination is indicated for pregnant women during each pregnancy, preferably between 27 and 36 weeks of gestation, to prevent pertussis in their infants and themselves. The safety of hepatitis A vaccination during pregnancy has not been determined, so the risk should be weighed against the benefit. All pregnant women should be screened for hepatitis B surface antigen (HBsAg). If HBsAg is positive, their children should receive hepatitis B vaccine and hepatitis B immune globulin within 12 hours of birth. All women who are or will be pregnant during the influenza season should receive inactivated influenza vaccine to protect themselves and their babies.

INDIVIDUAL IMMUNOBIOLOGICS

Hepatitis A

Two inactivated hepatitis A (Chapter 148) vaccines are available in the United States. Seroconversion rates after a single dose of either vaccine in persons older than 1 year exceed 95%, and protection is expected to persist for at least 25 years.

Indications

For adults, the vaccine is indicated primarily for persons traveling to countries (generally those in the developing world) with high or intermediate

endemicity for hepatitis A, but it is also recommended for other groups at high risk for infection or for development of severe hepatitis. In addition, vaccine is routinely recommended for children 12 to 23 months of age. Vaccination also is recommended for persons aged 1 to 40 years for postexposure prophylaxis after close contact with an infected person or exposure to a contaminated food or water source. Health care workers have not been shown to be at higher risk than the general population for hepatitis A and do not need routine immunization. Although food handlers are not at increased risk for hepatitis A compared with the general population, the consequences of infection or suspected infection in this group, which can lead to extensive public health investigations, may make vaccination cost-effective in some settings. Doses vary by age and product. All schedules call for a second dose at least 6 months after the first dose.

Adverse Events

The most common adverse reaction after hepatitis A vaccination is tenderness and soreness at the injection site. Although rare and more serious adverse events have been reported in temporal association with vaccination, no causal relationships have been established.

Hepatitis B

Hepatitis B (Chapter 148) vaccine was the first vaccine known to prevent cancer. It also can prevent acute and chronic complications of hepatitis B, including an estimated 1800 deaths annually in the United States from liver cancer, cirrhosis, and fulminant hepatic disease. Currently produced vaccines are derived from insertion of the gene for HBsAg into *Saccharomyces cerevisiae.* When it is administered in a three-dose series, hepatitis B vaccine produces adequate antibody responses (anti-HBs ≥ 10 IU/L) in more than 90% of healthy adults younger than 40 years and in more than 95% of normal infants, children, and adolescents. By age 60 years, protective levels of antibody develop in only 75% of vaccinated persons. The duration of vaccine-conferred immunity is not known, although follow-up of vaccinees for more than 20 years indicates persistence of protection against clinically significant infections (i.e., detectable viremia and clinical disease). Booster doses are not currently recommended. Vaccine must be injected intramuscularly in the deltoid.

Indications

Hepatitis B vaccine is indicated for adults at increased risk of infection (see Fig. 18-1 and E-Table 18-1), including all persons 19 through 59 years of age with diabetes. Vaccination may be offered at the physician's discretion to persons 60 years of age or older with diabetes. Universal screening for HBsAg is recommended for all pregnant women; three doses of vaccine and one dose of hepatitis B immune globulin are recommended for infants of acutely or chronically infected mothers.

Adverse Events

The major adverse reaction is soreness at the injection site. Rare instances of Guillain-Barré syndrome, leukoencephalitis, optic neuritis, transverse myelitis, rheumatoid arthritis, type 1 diabetes, and autoimmune disease have been reported, but causal associations have not been confirmed with any systemic immune complications.

Human Papillomavirus

Two licensed human papillomavirus (HPV) vaccines contain the L1 capsid protein of types 16 and 18, which account for about 70% of cases of cervical cancer. The quadrivalent vaccine (HPV4), which also contains the L1 capsid protein of types 6 and 11 that are the most common causes of anogenital warts, is the only HPV vaccine licensed for boys and men.[4] Routine vaccination of 11- to 12-year-old girls and boys is recommended in a three-dose schedule at 0, 1 to 2, and 6 months. Catch-up vaccination should be undertaken for females through 26 years of age, all males through 21 years of age, and immunocompromised males and men who have sex with men through age 26 years. Catch-up vaccination may also be considered for other men 22 to 26 years of age. Women with a prior abnormal Papanicolaou smear and persons with genital warts should be vaccinated to prevent persistent infection with types of HPV they may not yet have acquired.

Adverse Events

The most commonly reported local symptoms are injection site pain, redness, and swelling. The most common generalized symptoms are dizziness, syncope, nausea, vomiting, fatigue, headache, fever, and urticaria. Anaphylaxis is very rare.

Influenza

Influenza vaccines for seasonal influenza include intramuscular and intradermal inactivated influenza vaccine, which may contain three or four influenza split or subvirion virus types—A(H3N2), A(H1N1), and one or two B strains—and intranasal live attenuated influenza vaccine. Live attenuated vaccine, which consists of four cold-adapted, temperature-sensitive attenuated viruses, one for each of the expected circulating strains, uses viruses that have been reassorted with circulating strains to contain six internal genes from the parent virus and genes for the surface hemagglutinin and neuraminidase of an A(H3N2), A(H1N1), and two B strains.

A recombinant inactivated influenza vaccine contains no egg protein and may be given to persons 18 to 49 years of age who experience hives after eating eggs; the alternative is to give the standard, egg-derived, inactivated vaccine followed by 30 minutes of observation. Persons with more severe symptoms after eating eggs may either receive the recombinant vaccine or be referred to a physician with expertise in management of allergic conditions.

Indications

Annual influenza (Chapter 364) vaccination is indicated for everyone 6 months of age and older, but especially persons at high risk of complications from the disease: all children aged 6 through 59 months; all persons aged 50 years and older; adults and children who have chronic pulmonary, cardiovascular, renal, hepatic, neurologic, hematologic, or metabolic disorders; persons who are immunosuppressed; women who are or will be pregnant during the influenza season; children and adolescents who are receiving long-term aspirin therapy and who might be at risk for experiencing Reye syndrome after influenza virus infection; residents of long-term care facilities; American Indians/Alaska Natives; and persons who are morbidly obese. To reduce transmission of influenza to high-risk patients, health care personnel[5] and household contacts of high-risk patients, including contacts of children younger than 5 years, also should be vaccinated annually.

The efficacy of inactivated influenza vaccine varies with the host's condition and the degree to which antigens in the vaccine match viruses that circulate during the following season. Provided the match is good, the vaccine's efficacy is usually 50% to 70% for healthy adults younger than 65 years. Effectiveness varies but averages about 60% in preventing laboratory-confirmed outpatient illness in persons 50 years and older but is only about 35% in the institutionalized elderly.[6] Live attenuated vaccine is licensed only for nonpregnant persons aged 2 through 49 years without underlying conditions that place them at high risk of complications from influenza. It also can be used for appropriately aged contacts of high-risk patients but is not recommended for contacts of severely immunosuppressed patients, such as patients with bone marrow transplants. Live attenuated vaccine is more than 85% effective in young children. In healthy adults, live attenuated vaccine and inactivated influenza vaccine are similarly effective.

Influenza vaccination also reduces cardiovascular events. Vaccination efforts should begin as soon as the vaccine becomes available, usually by October, and should continue throughout the season. Peak influenza activity usually recurs in January or February, and influenza season continues through March.

Adverse Events

The most common side effect of inactivated vaccine is soreness at the injection site. Fever, malaise, and myalgia may begin 6 to 12 hours after vaccination and persist for 1 or 2 days, although such reactions are most common in children exposed to vaccine for the first time. The most common adverse events after live attenuated influenza vaccine in adults are runny nose, headache, and sore throat. Severe allergic reactions are rare, including Guillain-Barré syndrome in about one case per 1 million doses.

Measles

Indications

Measles (Chapter 367) immunization is recommended for all persons born in or after 1957 without laboratory evidence of immunity, laboratory confirmation of prior disease, or prior appropriate vaccination. Children should routinely receive two doses of MMR vaccine—one at 12 to 15 months of age and one at 4 to 6 years of age. Most adults are considered to have been appropriately vaccinated if they received one dose of vaccine on or after their first birthday. However, adults who are at increased risk of exposure to measles or transmission of it (e.g., health care workers, college students, international travelers) should receive a second dose if they did not get a second dose as children, unless they have serologically documented immunity, have laboratory confirmation of disease, or were born before 1957. Persons embarking

on foreign travel should have received two doses of MMR vaccine or have other evidence of measles immunity as defined before. Persons born before 1957 are usually immune as a result of natural infection and do not require vaccination, although vaccination is not contraindicated if they are believed to be susceptible.

During institutional outbreaks of measles, all persons who have not received two doses or who lack other evidence of measles immunity should be vaccinated. Although measles vaccine can be administered only with mumps and rubella as MMR, individuals already immune to one or more of the components may receive MMR without harm.

Measles vaccine is contraindicated for pregnant women on theoretical grounds, for persons with moderate to severe acute febrile illnesses, and for persons with altered immunocompetence, except those with HIV infection who are not severely immunocompromised. Patients with anaphylactic reactions to eggs can be vaccinated without prior skin testing.

Adverse Events

MMR vaccine can cause fever (<15%), rash (5%), transient lymphadenopathy (20% of adults), or parotitis (<1%). Febrile reactions, which usually are otherwise asymptomatic, generally occur 7 to 12 days after vaccination and persist for 1 or 2 days. MMR vaccination can rarely cause anaphylaxis, febrile seizures in children, thrombocytopenic purpura, transient arthralgia, and measles inclusion body encephalitis in persons with demonstrated immunodeficiencies.

Meningococcal Vaccines

Three quadrivalent meningococcal vaccines are available against disease caused by serogroups A, C, Y, and W135: meningococcal polysaccharide vaccine (MPSV4), which consists of 50 μg of polysaccharide of each of the four serogroups and is licensed for persons 2 years of age and older, and two meningococcal conjugate vaccines (MenACWY). A fourth vaccine, Hib-MenCY-TT, including *H. influenzae* type b plus meningococcal serotypes C and Y, was licensed in 2012 only for children ages 6 weeks through 18 months.

One conjugate vaccine consists of 4 μg of each polysaccharide covalently linked to 48 μg of diphtheria toxoid and licensed for persons 9 months to 55 years of age. The other conjugate vaccine consists of polysaccharide linked to CRM_{197} and is licensed for persons 2 months to 55 years of age. The four serogroups in each vaccine account for approximately two thirds of meningococcal disease in the United States and about 75% of the disease in persons 11 years of age or older (Chapter 298). Serogroup A and C polysaccharide vaccines are 85 to 100% efficacious in epidemic settings; vaccination with Y and W polysaccharides induces bactericidal antibodies and is presumed to be efficacious. In contrast to polysaccharide vaccines, conjugate vaccines induce immunologic memory, result in higher and more durable levels of high-avidity antibodies, and induce herd immunity. The duration of immunity for both MPSV4 and MenACWY is estimated at between 3 and 5 years.

Indications

Routine vaccination with MenACWY is recommended for all adolescents at 11 through 18 years of age, with a first dose administered at age 11 or 12 years and revaccination at age 16 years, or a first dose between 13 and 15 years and revaccination at age 16 to 18 years. Meningococcal vaccination once is also recommended for college freshmen who have not previously been vaccinated and will live in dormitories, military recruits, persons at risk during a community outbreak attributable to a vaccine serogroup, and persons who travel to or live in areas with hyperendemic or epidemic disease (e.g., the "meningitis belt" of sub-Saharan Africa, stretching from Mauritania to Ethiopia). For some persons at very high risk of meningococcal disease (e.g., microbiologists with frequent exposure to *Neisseria meningitidis* in culture and persons with persistent complement component deficiencies, splenic dysfunction, or asplenia), revaccination is recommended every 5 years.

MenACWY can be used for persons 2 months to 10 years of age with high-risk conditions but is not recommended routinely for this age group. For persons older than 55 years with an indication for vaccine, a single dose of MPSV4 is preferred. For persons now aged 56 years and older who were vaccinated previously with MenACWY and are recommended for revaccination or for whom multiple doses are anticipated (e.g., persons with asplenia and microbiologists), MenACWY is preferred.

Adverse Events

The major adverse reactions to MPSV4 are local reactions and systemic symptoms, such as headache and malaise, which generally persist for 1 or 2 days. The incidence of local reactions and low-grade fever is slightly higher after MenACWY than after MPSV4. An excess risk of Guillain-Barré syndrome was initially reported after MenACWY vaccines but has not been confirmed in subsequent studies.

Mumps

Indications

Mumps (Chapter 369) vaccine is indicated for all persons without evidence of immunity. For most adults, such evidence consists of a prior history of vaccination on or after the first birthday, laboratory evidence of immunity, or laboratory confirmation of disease. For adults at high risk, including health care workers, international travelers, and students at post-high school educational institutions, two doses of mumps vaccine constitute acceptable evidence of immunity. Most persons born before 1957 can be considered immune as a result of natural infection, although vaccination is not contraindicated if such persons are thought to be susceptible.

Adverse Events

Adverse events after the vaccine strain used in the United States are uncommon but include fever, parotitis, and allergic manifestations. Thrombocytopenic purpura has been reported rarely after MMR. Mumps vaccine is contraindicated for pregnant women on theoretical grounds, for persons with moderate to severe acute febrile illnesses, and for persons with altered immunocompetence. When it is combined with measles vaccine, it may be given to persons with asymptomatic HIV infection and considered for persons with symptomatic infection if they are not severely immunocompromised. Patients with anaphylactic reactions to eggs can be vaccinated without skin testing.

Pertussis Vaccine

Each of the two vaccines licensed for boosting immunity to pertussis in adults is combined with tetanus and diphtheria toxoids, and they have a lower content of pertussis antigens compared with the childhood pertussis-containing vaccines (Tdap). Boostrix (GlaxoSmithKline), which is licensed for adolescents and adults 10 years of age and older, contains three pertussis antigens—toxoid (PT), filamentous hemagglutinin (FHA), and pertactin (PRN). Adacel (Sanofi Pasteur), which is licensed for 10- through 64-year-olds, contains five pertussis antigens: PT, FHA, PRN, and two fimbriae. Both vaccines, when they are administered to previously vaccinated adolescents and adults, induce serologic responses that are comparable to those induced with effective childhood vaccination.

Indications

A single dose of Tdap is indicated for all adolescents at 11 to 12 years of age. Older adolescents and adults who have not received Tdap should get it instead of their next scheduled Td booster. Tdap can be given at any interval after a prior Td. All pregnant women should receive one dose of Tdap vaccine during each pregnancy, optimally between 27 and 36 weeks of gestation to maximize maternal antibody response and passive antibody transfer to the infant. If they have not been vaccinated during pregnancy, women should receive Tdap post partum if they have never previously been vaccinated with it. With the exception of pregnant women, booster doses of Tdap are not recommended.

Adverse Events

Adverse events, usually local reactions, are similar with the adult preparation of tetanus and diphtheria toxoids (Td) alone (see tetanus and diphtheria section later).

Pneumococcal Vaccines

Two pneumococcal vaccines are available for adults. Pneumococcal polysaccharide vaccine (PPSV23) consists of purified polysaccharide capsular antigens from the 23 types of *Streptococcus pneumoniae* that are responsible for 85 to 90% of the bacteremic disease in the United States (Chapter 289). Most adults, including elderly patients and those with alcoholic cirrhosis and diabetes mellitus, have a two-fold or greater rise in type-specific antibodies within 2 to 3 weeks of vaccination. Vaccination is approximately 60% effective against invasive pneumococcal disease, but its efficacy against pneumonia in high-risk populations, such as patients with alcoholic cirrhosis or Hodgkin disease, is not clear.

Pneumococcal conjugate vaccine (PCV13), licensed in 2011 for adults aged 50 years and older, should be administered once to eligible adults

because it is expected to add protection to that offered by PPSV23. Ideally, PCV13 should precede PPSV23 by at least 8 weeks in immunocompromised persons over age 19 years and by at least 6 months in persons who are age 65 years or older and are not immunocompromised; if PPSV23 is administered first, an interval of 1 year should elapse before PCV13 is administered.

Indications

The preponderance of information supports the use of pneumococcal vaccines in high-risk populations, including all persons 65 years and older, persons 19 years or older who smoke cigarettes, and patients with asthma. Special efforts should target hospitalized patients. Approximately two thirds of patients who are admitted later with pneumococcal disease had been hospitalized for other reasons within the preceding 5 years. The newer PCV13 vaccine is recommended for all adults over age 65 years and for adults 19 years of age and older with immunocompromising conditions, functional or anatomic asplenia, cerebrospinal fluid leaks, or cochlear implants.

Because immunity may decrease 5 years or more after initial vaccination with PPSV23, a single booster dose of PPSV23 should be considered at that time for adults at highest risk of disease (such as asplenic patients) and for adults who lose antibody rapidly (such as patients with nephrotic syndrome or renal failure). Persons 65 years or older who received a dose more than 5 years earlier when they were younger than 65 years also should be revaccinated.

Adverse Events

Local reactions to PPSV23 are frequent, but less than 1% of vaccinees experience severe local reactions or systemic symptoms such as fever and malaise. Severe events, such as anaphylaxis or Arthus-like reactions at the site of injection, are rare. Because of the rarity of severe reactions in revaccinated patients, persons with indications for vaccination but with unknown histories of prior vaccination should be vaccinated. PCV13 reactions include pain, redness, and swelling at the injection site; limitation of movement of the injected arm; fatigue; and headache.

Poliomyelitis

Since 2000, inactivated poliovirus vaccine (IPV) has replaced the live attenuated oral poliovirus vaccine (OPV) in the United States because OPV vaccine caused about eight polio cases per year in the United States among recipients or their contacts (Chapter 379). OPV is still the vaccine used in most countries around the world.

Indications

Routine vaccination of persons 18 years of age or older is not recommended. If adults who are unvaccinated, are incompletely vaccinated, or have unknown vaccination status travel to areas where wild poliovirus is endemic or epidemic, they should receive a series of three doses: two doses of IPV administered at an interval of 4 to 8 weeks, with a third dose adminitered 6 to 12 months after the second. If three doses of IPV cannot be administered, alternatives include the following: three doses of IPV administered 4 weeks or more apart; if less than 8 weeks remain before protection is needed, two doses of IPV administered 4 weeks or more apart; and if less than 4 weeks remain before protection is needed, a single dose of IPV. If fewer than three doses are administered, the remaining doses needed to complete a three-dose series should be administered when feasible, at the intervals recommended, especially if the person remains at increased risk for poliovirus exposure.

As a precaution, adults (≥18 years of age) who are traveling to areas where poliomyelitis cases are occurring and who have received a routine series with either IPV or OPV in childhood should receive another dose of IPV before departure.[7] For adults, available data do not indicate the need for more than a single lifetime booster dose with IPV.

Adverse Events

Minor local reactions (pain, redness) commonly occur after IPV. Because IPV contains trace amounts of streptomycin, polymyxin B, and neomycin, allergic reactions may occur in persons allergic to these antibiotics.

Rabies

Two inactivated rabies vaccines are licensed in the United States.[8] Human diploid cell vaccine (HDCV), which is prepared from the Pitman-Moore strain of rabies virus, also contains small amounts of neomycin sulfate, albumin, and phenol red indicator. The purified chick embryo cell vaccine (PCECV), which is prepared from the Flury LEP rabies virus strain, also contains small amounts of polygeline, human serum albumin, potassium glutamate, and sodium EDTA. Both vaccines are given intramuscularly.

Indications

Rabies (Chapter 414) vaccine is indicated for pre-exposure prophylaxis of high-risk persons, including animal handlers, selected laboratory and field workers, and persons traveling for more than 1 month to areas where rabies is a constant threat. For both rabies vaccines, the pre-exposure regimen consists of three 1-mL intramuscular injections on days 0, 7, and 21 or 28. Post-exposure treatment depends on prior exposure to vaccine (Chapter 414). Persons being treated for the first time should be given human rabies immune globulin as well as four doses of vaccine at days 0, 3, 7, and 14.

Adverse Events

Local reactions (e.g., pain at the injection site, redness, swelling, and induration) are common after both rabies vaccine preparations. Hypersensitivity reactions can occur after booster doses.

Rubella

Indications

One dose of rubella vaccine (Chapter 368) is indicated for adults born in 1957 or later without evidence of immunity and for women of any age who lack evidence of immunity and who are considering becoming pregnant. Persons without a prior history of vaccination on or after the first birthday, laboratory evidence of immunity, or laboratory confirmation of disease should be considered as lacking evidence of immunity. A single dose of vaccine is 95% or more effective. Many persons receive two doses of rubella vaccine by the two-dose schedule of MMR.

Adverse Events

Follow-up of pregnant women who had no evidence of immunity and who received rubella vaccines within 3 months of the estimated date of conception show no evidence of defects compatible with congenital rubella syndrome in their offspring. Nevertheless, vaccine is contraindicated in pregnant women on theoretical grounds, and conception should be delayed for 1 month after rubella vaccination.

Arthralgia develops among about 25% of nonimmune postpubertal females after vaccination with rubella vaccine. Symptoms generally begin 1 to 3 weeks after vaccination, usually are mild, persist for about 2 days, and rarely recur. These symptoms are less common in postpubertal males compared with females. Other infrequent adverse events include transient peripheral neuritis and pain in the arms and legs. Thrombocytopenic purpura is rare when rubella vaccine is administered as MMR. Rubella vaccine is contraindicated for persons with moderate to severe acute illnesses and for persons with reduced immunocompetence. When it is given with measles vaccine, it may be administered to persons with asymptomatic HIV infection and considered for symptomatic persons who are not severely immunocompromised. Rubella vaccine is grown in human diploid cells and can be administered without problems to persons with allergy to eggs.

Tetanus and Diphtheria

Tetanus (Chapter 296) toxoid is one of the most effective immunizations, with more than 95% protection after a primary series of three doses. In persons aged 7 years or older, it should always be used in combination with diphtheria (Chapter 292) toxoid (Td), which is more than 85% effective in preventing disease. Combinations that also include pertussis antigens (Tdap) are preferred to Td for routine immunization of adolescents and adults who have yet to receive Tdap as well as for pregnant women (for whom Tdap is recommended during every pregnancy).[9] Doses need not be repeated if the schedule is interrupted. A booster dose of Td is recommended every 10 years.

Indications

After a wound, persons of unknown immunization status or persons who have received fewer than three doses of tetanus toxoid should receive a dose of Tdap or Td regardless of the severity of the wound. Td also is indicated for persons who have previously received three or more doses if more than 10 years has elapsed since the last dose, in the case of clean and minor wounds, and if more than 5 years has elapsed for all other wounds. Persons who have never received a dose of Tdap should receive it instead of Td for wound management. Tetanus immune globulin should be administered simultaneously at a separate site to persons who have wounds that are not clean and minor if they have not previously received at least three doses of toxoid.

Adverse Events

Most reactions to Td consist of local inflammation and low-grade fever. Exaggerated local (Arthus-like) reactions, with extensive painful swelling, often from shoulder to elbow, are occasionally reported 2 to 8 hours after receipt of a diphtheria- or tetanus-containing vaccine, particularly in persons who have received frequent doses of diphtheria or tetanus toxoid. Severe systemic reactions, such as generalized urticaria, anaphylaxis, Guillain-Barré syndrome, and other neurologic complications, rarely have been reported after receipt of tetanus toxoid.

Varicella: Chickenpox

A single dose of live attenuated varicella vaccine (Oka strain), which can be combined with MMR vaccine, protects 70 to 90% of recipients against any disease and more than 95% of recipients against severe disease, but a two-dose schedule is recommended. Whether immunity wanes with increasing time after vaccination is unclear. Use of vaccine has been associated with dramatic decreases in the incidence of varicella.

Indications

Varicella vaccine is indicated routinely for all children without a contraindication. The two-dose schedule includes vaccination at 12 to 15 months of age and again at 4 to 6 years of age. For persons who previously received just a single dose, a catch-up second vaccination is recommended, preferably at least 3 months after the first dose. Persons 13 years or older without evidence of immunity to varicella should receive two doses at least 4 weeks apart. Evidence of immunity to varicella includes documentation of age-appropriate vaccination with two doses of varicella vaccine at least 28 days apart, laboratory evidence of immunity or laboratory confirmation of disease, birth in the United States before 1980, or diagnosis or verification of a history of varicella or herpes zoster disease by a health care provider. Serologic screening of adults in some situations may be cost-effective, provided that identified susceptible adults are vaccinated. Serologic testing is not indicated after vaccination. The vaccine is contraindicated in persons who are immunocompromised, persons with anaphylactic allergies to vaccine components, and pregnant women. Post-exposure vaccination within 3 days of exposure can reduce the likelihood of symptomatic infection by about two-thirds. Varicella vaccine is temperature sensitive, so it must be stored at −15° C or colder to retain potency and should be discarded if it is not used within 30 minutes of reconstitution.

Adverse Events

The most common side effect is soreness at the injection site, which is reported in 25 to 35% of recipients 13 years or older. Varicella-like rashes at the injection site (median of two lesions) have been reported in 3% of recipients in this age group after the first dose and in 1% after the second dose. Nonlocalized rashes with a median of five lesions have been reported in 5.5% of recipients after the first dose and in 0.9% after the second dose. Although the vaccine virus can cause herpes zoster (shingles), especially in children, the incidence is substantially lower than would be expected after natural varicella (Chapter 375). More severe events in temporal relation to the vaccine have been reported rarely, but a causal relationship has not been established. Transmission of vaccine virus to a contact is extremely rare and probably occurs only from vaccinees in whom a varicella-like rash developed.

Varicella: Zoster

The varicella-zoster virus vaccine, which is approximately 14 times more potent than the varicella vaccine used routinely in children, reduces zoster by about 50% and post-herpetic neuralgia by about two thirds in persons 60 years of age or older. The efficacy against zoster declines after age 70 years, but protection against post-herpetic neuralgia continues. As for the varicella-chickenpox vaccine, special freezer storage is required.

Indications

A single dose of zoster vaccine is recommended for persons 60 years of age or older, even if they have a prior history of zoster. It is not necessary to elicit a history of varicella or to test for varicella immunity before administering the vaccine. The vaccine is not recommended for immunocompromised persons or pregnant women.

Adverse Events

Local reactions (erythema, pain or tenderness, and swelling at the injection site) are common. Severe reactions were of similar incidence in vaccine and placebo recipients in clinical trials.

VACCINES INTENDED PRIMARILY FOR INTERNATIONAL TRAVELERS

Evaluation of people before travel should include a review and provision of routine vaccines recommended on the basis of age and other individual characteristics. Recommendations for specific vaccines related to travel will depend on itinerary, duration of travel, and host factors. Detailed recommendations are available at *www.cdc.gov/travel*.[10]

Japanese Encephalitis Vaccine

Indications

Japanese encephalitis (Chapter 383) vaccine is indicated primarily for travelers to Asia who will spend a month or longer in endemic areas during the transmission season, especially if travel will include rural areas. In all instances, travelers should be advised to take personal precautions to reduce exposure to mosquito bites. An older vaccine was reported to be 80 to 91% effective in preventing clinical disease, and the current whole virus inactivated vaccine (Ixiaro, Intercell Biomedical) was licensed on the basis of comparable immunogenicity. The primary series consists of two 0.5-mL doses given intramuscularly on days 0 and 28, with the second dose administered at least 1 week before travel (see Table 18-2). If the primary series was administered more than 1 year previously, a booster dose may be given before the next potential exposure to the virus.

Adverse Events

Headache and myalgia and local reactions (pain and tenderness) occur in more than 10% of vaccinees. However, the incidence rates of these events were similar to those in a comparison group that received a placebo with aluminum hydroxide.

Typhoid Vaccine

Indications

Two types of vaccines, a live attenuated Ty21a oral vaccine and a capsular polysaccharide vaccine (ViCPS), appear to be of comparable efficacy (50 to 77%). Typhoid (Chapter 308) vaccine is indicated primarily for travelers to areas where the risk of prolonged exposure to contaminated food and water is high. Because the vaccine is not always effective, food and water precautions are still essential. The vaccine also may be considered for family or other intimate contacts of typhoid carriers and laboratory workers who work with *Salmonella typhi.* For adults and children 6 years and older, either of the vaccines may be used. For Ty21a, one enteric-coated capsule is taken every other day for four doses. Alternatively, a single dose of the ViCPS vaccine may be given. The duration of protection with Ty21a is not known; repetition of the primary series is recommended every 5 years for persons at risk. Boosters are recommended every 2 years for the ViCPS vaccine if persons continue to be at risk. The ViCPS vaccine can be given to children as young as 2 years.

Adverse Events

Fever and headache may occur after receipt of typhoid vaccines. Stomach pain, nausea, and rash are rarely observed.

Yellow Fever Vaccine

Indications

Yellow fever (Chapter 381) occurs only in areas of South America and Africa. Vaccination with a single dose of the live attenuated 17D strain of virus confers protection to almost all recipients for at least 10 years. A booster dose is recommended every 10 years for persons at continued risk of exposure to yellow fever.

Adverse Events

Adverse reactions (fever, aches, and soreness, redness, or swelling where the injection was given) occur in up to 25% of vaccinees. Anaphylaxis has been reported in 0.8 to 1.8 persons per 100,000 doses of vaccine distributed. A rare syndrome (0.25 case per 100,000 doses distributed) of multiple organ system failure or viscerotropic disease with high rates of mortality has been reported, primarily among older adults and persons who have undergone thymectomy or have severe thymic dysfunction. Meningoencephalitis, Guillain-Barré syndrome, acute disseminated encephalomyelitis, and bulbar palsy have been reported in 1 to 2 persons per 100,000 doses and are more common in older vaccines. In patients 60 years and older who are going to spend time in yellow fever–endemic zones, yellow fever vaccine should be administered with caution and only after careful counseling. Yellow fever vaccine should not be

given to immunocompromised persons or persons with anaphylactic allergies to eggs. The vaccine is contraindicated in pregnant women on theoretical grounds, although pregnant women who must travel to a high-risk area may be vaccinated.

VACCINES FOR POSSIBLE BIOTERRORISM AGENTS

Anthrax Vaccine

Anthrax (Chapter 294) vaccine adsorbed (AVA) is prepared from a cell-free filtrate of a nonencapsulated strain of anthrax and contains many cell products, including protective antigen. Protective antigen is responsible for binding to cells, allowing transport of lethal factor and edema factor into host cells. A recombinant protective antigen (rPA) vaccine is in clinical trials.

Indications

Pre-exposure prophylaxis consists of a three-dose primary intramuscular schedule at 0, 4 weeks, and 6 months, with booster doses at 12 and 18 months, followed by annual boosters. Protective efficacy of an earlier form of the vaccine against cutaneous anthrax was 92.5%. Animal models suggest efficacy against inhalation anthrax. Pre-exposure vaccination is recommended for persons engaged in work involving exposure to high concentrations of *Bacillus anthracis* or in activities with high potential for aerosol production. Vaccine is recommended in conjunction with antibiotics for postexposure prophylaxis after exposure to aerosolized *B. anthracis* spores. The recommended regimen is three doses of AVA administered at 0, 2, and 4 weeks, combined with at least 60 days of antibiotics, which should be continued for at least 14 days after the third dose of vaccine (Chapter 294).

Adverse Events

The most common adverse events are local reactions, including subcutaneous nodules, which are thought to be due to the deposition of the aluminum-containing adjuvant in subcutaneous tissue. These adverse events are less common with intramuscular injections than with subcutaneous injections.

Smallpox Vaccine

Smallpox vaccine uses vaccinia virus, an orthopox virus that is distinct from variola and cowpox viruses and that provides cross-protection from smallpox. Smallpox vaccine is close to 100% effective when it is administered properly with a bifurcated needle. Vaccination also prevents or modifies disease when it is administered within 3 to 4 days of exposure and perhaps even after greater delays. The skin usually does not need any special preparation. If alcohol is used for cleaning, the skin should be allowed to dry before vaccination to avoid inactivation of the vaccine. The needle is held perpendicular to the skin with 15 punctures for all vaccinees, made rapidly with enough vigor to ensure that a trace of blood appears within 15 to 20 seconds. With a primary take, the vaccination site should become reddened and pruritic within 3 or 4 days after vaccination; a large vesicle with a red areola forms and becomes pustular by 7 to 11 days. The lesion scabs by the third week.

Indications

The vaccine is indicated for persons who work with orthopox viruses. To increase preparedness for a smallpox attack, vaccination is often recommended for persons who will serve on public health or health care response teams. The duration of immunity is unclear. Revaccination is recommended at least every 10 years for persons who continue to be at risk. Contraindications include history or presence of eczema, other chronic or exfoliative skin conditions, and immunosuppression or pregnancy in the patient or a close household or other contact. Persons who are younger than 1 year, are breastfeeding, or have allergies to vaccine components should not be vaccinated. Because of reports of post-vaccination cardiac events, vaccination should be deferred in persons with ischemia or other severe heart diseases or persons at high risk for ischemic heart disease events (*http://emergency.cdc.gov/agent/smallpox/vaccination/index.asp*). In the event of exposure to variola, there are no contraindications. Should variola be introduced into a community, vaccination would be indicated for all exposed persons and their close contacts to prevent further spread, and recommendations for more widespread vaccination would have to be evaluated on a case-by-case basis.

Adverse Events

Fever is the most common adverse event. Other more serious complications include eczema vaccinatum, which is a local or disseminated vaccinia infection in persons with a history of eczema or other exfoliative dermatitis; vaccinia necrosum, which occurs in immunocompromised persons; autoinoculation, especially of the eye, which can cause keratitis and scarring; generalized vaccinia; myopericarditis; and encephalitis. The risk for death from vaccinia is about one case per 1 million primary vaccinations.

Other Agents

Other organisms or products that have been considered potential bioterrorism threats include plague (Chapter 312) and botulinum toxin (Chapter 296). Poisoning with botulinum toxin can be treated with a trivalent antitoxin available from the Centers for Disease Control and Prevention (see *http://www.cdc.gov/laboratory/drugservice/formulary.html*). An experimental heptavalent botulinum toxoid can be obtained from the Centers for Disease Control and Prevention for laboratory workers at high risk for exposure to toxin. Pre-exposure vaccination is not warranted or feasible for the general population.

OTHER VACCINES

A protein-conjugated vaccine for *H. influenzae* type b (Hib) should be considered for some adults at high risk for invasive Hib disease (e.g., asplenia, sickle cell disease, or recipient of a hematopoietic stem cell transplant) if they have not previously received Hib vaccine.

REVIEW QUESTIONS

1. Tdap vaccine is recommended to be given only once for all groups except which of these?

A. Pregnant women
B. Parents of children younger than 2 years
C. Adults 65 years of age and older
D. Children 11 years of age or older who did not complete their DTaP vaccine series
E. Adolescents and adults entering college

Answer: A Pregnant women should receive Tdap vaccine during each pregnancy to offer protection to each newborn. Available data indicate fairly rapid waning of pertussis immunity after Tdap vaccination and no significant adverse events after repeated Td or Tdap vaccinations with short intervals between them. For more information, see *http://www.cdc.gov/mmwr/preview/mmwrhtml/mm6207a4.htm*.

2. Persons who are at increased risk of meningococcal disease and for whom meningococcal vaccine is recommended include all except which of the following?

A. Persons without spleens or whose spleens are not functional (e.g., have sickle cell disease)
B. Persons with persistent complement deficiencies
C. Persons 65 years and older
D. Microbiologists regularly working with *Neisseria meningitidis* isolates
E. Persons traveling to sub-Saharan Africa

Answer: C Available data indicate increased risk of meningococcal disease for all the listed groups except persons 65 years and older. *http://www.cdc.gov/mmwr/pdf/rr/rr6202.pdf*.

3. Pneumococcal conjugate vaccine is recommended for which of these adult groups?

A. Persons with nephrotic syndrome
B. Persons with liver cirrhosis
C. Persons with chronic obstructive pulmonary disease
D. Persons with coronary artery disease
E. Persons with diabetes

Answer: A Most of the additional benefit of pneumococcal conjugate vaccination, when it is used to supplement pneumococcal polysaccharide vaccination, accrues to persons with iatrogenic or disease-related immunocompromising conditions, including nephrotic syndrome, as well as persons with functional or anatomic asplenia, cerebrospinal fluid leaks, and cochlear implants. For more information, see *http://www.cdc.gov/mmwr/preview/mmwrhtml/mm6140a4.htm*.

4. Adults at increased risk of hepatitis B infection who should receive hepatitis B vaccine include which of the following?

A. Persons with chronic obstructive pulmonary disease
B. Persons with coronary artery disease
C. Persons with nephrotic syndrome not on dialysis
D. Persons 19 to 59 years old with diabetes mellitus
E. Persons 65 years and older

Answer: D Persons who have frequent contact with contaminated blood or body fluids are at increased risk of hepatitis B infection. Adults 19 to 59 years of age with diabetes mellitus also are at increased risk of hepatitis B infection, at least in part because of poor infection control practices with assisted blood glucose monitoring (see *http://www.cdc.gov/mmwr/pdf/wk/mm6050.pdf*). Therefore, the Centers for Disease Control and Prevention recommend that adults with diabetes mellitus younger than 60 years receive hepatitis B vaccine.

5. Human papillomavirus (HPV) vaccine is recommended for

A. Routine and catch-up vaccination for boys beginning at 11 years and men through 21 years
B. Persons 65 years and older
C. Only men who have sex with men
D. Girls and women 11 to 50 years
E. Girls and boys beginning at 9 years of age

Answer: A HPV vaccine is recommended for persons primarily before they begin sexual activity and have been infected with HPV. The upper age range for both licensed vaccines is 26 years. Although the vaccine is licensed for both boys and girls beginning at the age of 9 years, it is recommended to begin at age 11 to 12 years, at the same time as other adolescent vaccines (Tdap and meningococcal vaccines). For more information, see *http://www.cdc.gov/mmwr/pdf/wk/mm6050.pdf* and *http://www.cdc.gov/mmwr/PDF/wk/mm5920.pdf*.

PRINCIPLES OF OCCUPATIONAL AND ENVIRONMENTAL MEDICINE

MARK R. CULLEN

In the first several decades after World War II, when many American workers came to enjoy coverage by health insurance—for everything *but* workplace injuries and illnesses—the myth grew that modern work is largely free of the risks of the industrial horrors of past eras. Starting in the 1970s, however, resurgence of societal and medical interest in these consequences of work found that diseases related to work are not truly extinct, just not well observed or studied. Occupational physicians, often cut off from mainstream medical practice, had difficulty in changing the perception, and most practicing internists were largely oblivious. It is now recognized that a substantial burden of ill health and disability is due to work-associated physical, chemical, and biologic hazards. Psychosocial aspects of work also may be injurious to health.

Although tens of thousands of toxic chemicals and other hazards can potentially cause or exacerbate a wide range of acute and chronic conditions, certain basic principles and clinical approaches apply broadly to general and specialty medical practice. This chapter outlines these basics, then briefly summarizes the most common occupational disorders seen by internists in

developed countries, and finally reviews the effects of the environmental exposures most likely to be encountered.

PRINCIPLES OF OCCUPATIONAL AND ENVIRONMENTAL DISEASE

It is widely imagined that the major health effects of environmental and occupational exposures are unique disorders best recognized by their failure to fit easily into other diagnostic categories (e.g., arsenic poisoning). In reality, *the major consequences of chemical and physical exposures are, without further exploration of an environmental connection, indistinguishable in clinical presentations from disorders that make up the bulk of outpatient and inpatient medical practice:* common rashes (Chapter 438), nonspecific liver function abnormalities (Chapter 147), wheezing and irritative symptoms of the upper and lower respiratory tract (Chapter 87), various cancers (Chapter 180), peripheral neuropathies (Chapter 420), dysphoria (Chapter 397), and nonspecific cognitive dysfunction (Chapter 402). Although a handful of pathologically distinct disorders still occur, such as silicosis (Chapter 93) and lead poisoning (Chapter 22), when an environmental or workplace agent causes overt disease, physiologic and radiographic studies typically reveal manifestations completely consistent with common diagnoses such as asthma (Chapter 87), contact dermatitis (Chapter 438), fatty liver (Chapter 152), and lung cancer (Chapter 191).

The underlying cause of such conditions will inevitably remain obscure unless the clinician adheres to a disciplined approach designed to investigate and to exclude occupational or environmental causes whenever it is appropriate. The best approach is consistent use of the occupational and environmental history, a short series of questions that can be expanded on the basis of the responses (see later). The point is that the internist cannot "wait" to consider occupational or environmental issues until other diseases have been ruled out without running the risk of missing almost every occupational and environmental effect that he or she will encounter.

Whatever the pathway or time course, exposure dose is the major determinant of the risk for development of disease. As in pharmacology (Chapter 29), it is impossible to make any meaningful statement about cause and effect without appreciation of dose. Consider, for example, the difference in health effects of aspirin at 65 mg, 650 mg, and 6500 mg (Chapter 37). Over this two-order magnitude of change, the chemical goes from having one therapeutic target organ to having many to being lethal. It is no different with lead or organophosphate pesticides or solvents, except that there is rarely as simple a way to determine dose as in the drug situation, where pill bottles are labeled, drug prescriptions are recorded, and blood or urine levels are readily available in most laboratories. This limitation is exacerbated because, unlike with drugs, the range of toxic exposures may vary far more widely. For example, water in a contaminated drinking well or poor indoor air in an office could have toxins at a level that is two, three, or even four orders of magnitude (i.e., 10,000 times) lower than the level that may have been evaluated in epidemiologic studies of workers or tested in animals. Fortunately, it is much easier to "range find" than one might presuppose (see later discussion of history), and eagerness for precision—often unattainable—should not interfere with obtaining the great amount of information that *can* be readily gleaned from the patient and is often sufficient to act on. The key point is that no attempt to apply clinical information in relation to work or environment can be useful without some effort to characterize exposure dose.

Environmental hazards may affect preferentially vulnerable populations—those with underlying disease, those at the extremes of life, those with atopy, and those with other serious health risks such as smoking or diabetes. Genetic variability may underlie some of these differences, but few relevant genes have been sufficiently characterized for use in practice. Clinical studies of a host of common occupational diseases have identified behavioral and constitutional cofactors; for example, smoking dramatically increases the risk of lung cancer in asbestos-exposed workers (Chapter 191). This interaction creates a double demand on the clinician—the presence of smoking or atopy in a young woman with cough not only does not *preclude* the possibility of an occupational cause of her asthma but rather actually *increases* the likelihood that such an exposure may be important.

The Occupational and Environmental History and Exposure Assessment

Key to determining whether work and other environmental exposures may be causing or contributing to adverse health is the exposure history. The approach to obtaining this information and to the use of available resources to corroborate and complement it depends on the clinical context. In primary and much specialty medical care, where it is anticipated that a patient will be observed during a long period into the future, the most important step is to establish the hazards to which the patient may be exposed at work presently, the activities that may have resulted in past harmful exposures potentially relevant to future health (because of a latency with tobacco), and whether the present residential environment (including air and water and food sources) is thought to be contaminated by harmful materials. The recommended approach is to use a simple questionnaire, which can be self-administered or supervised by a medical extender (E-Fig. 19-1). These instruments can then be reviewed together by the patient and physician as time permits and updated over time. When jobs or materials are noted but the actual generic exposures are unknown, the patient and available reference sources can be enlisted to "translate" the history into specifics, such as which metals are being welded or what is actually contained in a cleaning agent or plastic. This information is obligatorily maintained and supplied on request by employers in most developed countries in the form of fact sheets termed Material Safety Data Sheets, many of which can be easily found online as well. In this way, the ongoing and former exposures, which may have an impact on health, can be noted and, where important, incorporated into routine preventive care or clinical surveillance for sequelae.

For patients with new clinical complaints or recently diagnosed conditions, the question of an environmental cause looms more urgently, so the approach must be more focused. If symptoms or signs of acute or subacute illness are suggested, the *timing* of recent or unusual environmental exposures in relation to the symptoms is key—more important than specific chemical detail. For example, if the patient develops shortness of breath shortly after the introduction of a new chemical or process at work or after a leak or spill, that fact should drive further questions, such as Did others get sick as well? For recurrent symptoms, such as cough or rash, cyclic changes are most often the strongest clue: Do symptoms get worse on workdays and improve on days off or holidays? For more insidious symptoms, such as weakness or numbness of the extremities or new-onset hepatic dysfunction, the appropriate question would be whether the onset of the abnormality has followed by weeks or months some demonstrable change in the work or home environment. Again, the coincidence of others similarly affected may be more valuable than detailed knowledge of the constituents of that environment. When such a temporal pattern is suggested, further efforts are warranted to establish what exposure may have occurred and what its dose may have been, often in conjunction with a specialty consultation.

In the elucidation of evidently more chronic conditions, such as pulmonary fibrosis, chronic renal insufficiency, or a malignant neoplasm, an alternative approach is suggested because the exposure, if relevant, is usually remote. In this situation, a detailed query about current work or ambient environments is *not* likely to be helpful in differential diagnosis, although knowledge of a past exposure to an important hazard (such as silica, asbestos, or cadmium) might, on the basis of the knowledge of its effects, influence the sequence of the evaluation. However, it is generally more efficient to explore past exposures *after* the pathophysiologic disturbance has been characterized, focusing inquiry on factors known to cause or suspected of causing that disorder—as easily found in suggested texts or literature searches.

In acute or chronic cases, information about *what* the exposure has been (generically) must be augmented by an estimation of exposure dose. A brief exposure to a fume containing a small percentage of lead will not, in general, cause acute lead poisoning (although hosts may differ in their responses), nor will trace contamination of a drinking well with benzene typically cause blood dyscrasias. The patient will rarely be able to supply detailed information about past or even current "dose" but often can provide valuable clues: Did the exposure continue during many years? Were fumes or fibers grossly visible in the air? Were respirators or other protective gear necessary or offered? Have episodes of unprotected exposure ever resulted in irritation or acute discomfort? A positive reply to any of these questions would suggest "high" exposure, where the reference point is the level at which the risk for development of a health effect becomes substantial. Conversely, if exposure has occurred in an otherwise typical office or around a home renovation, the levels of exposure are more likely "low." Nevertheless, such low-level exposure does not exclude a health effect, especially one caused by idiosyncratic mechanisms or occurring in hosts who are more "sensitive" to chemical exposures, a health characteristic found in 2 to 10% of the population. Although not to be condoned because of potential broader public health consequences, exposures to trace contaminants in food and drinking water are uncommon causes of *perceptible* clinical problems. When concern about the exposure is high, information from patients can be readily supplemented by information from employers (with the patient's consent!) and regulatory or health

Occupational and Environmental Exposure History

Current employment (if not currently employed, fill out for last job held)

1. Job title _____
2. Name and address of employer _____
3. Nature of work _____
4. How many hours a week do you usually work? _____
5. Start date? _____ If ended, last day worked _____
   If ended, why did you leave? _____
6. Do you have to wear personal protective equipment (like a respirator or gloves or hearing protection) at your job? If yes, what kind(s) _____
7. Exposures at this job. For each, record whether "none," "a little," or "a lot"

	None	A little	A lot
Dust or fumes			
Organic solvents or thinners			
Other chemicals			
Noise			
Excessive heat			
Physical strain			
Mental stress			

Conflict between work and family

Any hazard at this job that you think might be making you sick? _____

Past employment

Please list all the jobs you had before this last one, working backward toward school. For each, list the title, years you held job, and whether there was any exposure you are worried about from that job.

Job title	Years held	Exposure of concern?

Were you ever in the military service?

If yes, what years? _____ Were you in an active war zone? _____

Where? _____

Did hazardous exposures in any of these jobs make you sick? _____

If so, explain _____

Environmental exposures

Are there any specific exposures in your home or neighborhood you are worried about?

If so, what? _____

Please tell us about your home environment:

1. Is your drinking water from a city or town source? Private well? Any health problems with the water? _____
2. Is your heating system oil? Gas? Electric? Any health problems with the heat? _____
3. Are there sources of pollution near your home? _____ What? _____
4. Does anyone smoke inside your home? _____ Who? _____
5. Does anyone have hobbies at home involving chemicals or industrial materials? If so, describe. _____
6. Does anyone bring dust or other materials home on clothes from work? If yes, what? _____

E-FIGURE 19-1. A questionnaire for use during the "intake" of new patients for ongoing primary or specialty care. The instrument may be self-administered or supervised by a medical extender; it should then be reviewed by the patient and physician and periodically updated.

authorities or by consultation with specialists who should know the levels of most workplace hazards in the community. Finally, with an appropriate understanding of the limits of testing and awareness of "timing" issues in relation to exposure (as with measuring drug levels), an increasing number of hazardous chemicals can be biologically measured in blood or urine. Reliable testing is currently available for most metals and some pesticides, and testing may become available for a broad array of organic chemicals in the foreseeable future. Random sampling for "unknowns" is rarely helpful and most often leads to erroneous inferences because trace chemicals are ubiquitous, that is, almost everyone will have a higher than average level of "something."

OCCUPATIONAL AND ENVIRONMENTAL HEALTH DISORDERS COMMON IN PRACTICE

Although almost any medical complaint or condition could in theory have an occupational or environmental cause or contribution, certain conditions encountered in medical practice *commonly* do (Table 19-1). For these conditions, attention to the history is most important and most often rewarding.

Asthma

Atopic men and women with preexisting airways disease tolerate irritants in the workplace poorly and may experience exacerbations in temporal relation to one or more exposures. More important, numerous antigens are extant in the workplace, from large proteins, such as latex and animal danders, to small molecules, such as isocyanates needed to set polyurethane. More than 250 agents have been well characterized, and many others are suspect. Virtually no profession or work is immune, and up to 20% of all adult-onset asthma may have a work component. Presentation is often nonspecific; timing of symptoms during or slightly staggered from exposure is the clue to diagnosis, keeping in mind that there may be a lag of several hours between exposure and cough or other symptoms. The reward for early recognition of such causes is the likelihood that airway inflammation will abate when the noxious exposure is eliminated[1,2]; otherwise, lifelong, often generalized asthma is the rule (Chapter 87).

Chronic Interstitial, Parenchymal, and Inflammatory Lung Disorders

The rounded opacities of silicosis (Chapter 93) and coal workers' pneumoconiosis (Chapter 93) radiographically resemble sarcoid (Chapter 95); chronic beryllium disease (Chapter 93), a granulomatous disorder caused by sensitization to this widely used light metal, is clinically identical to sarcoid in almost all respects, but a reasonably specific test for blood and bronchoalveolar lavage fluid is now available to distinguish them. Asbestosis (Chapter 93) is identical to idiopathic pulmonary fibrosis (Chapter 92) in every clinical way except that benign pleural changes often accompany asbestosis, and asbestosis tends to be more indolent and usually stops progressing when exposure ceases or within a few years thereafter. Hypersensitivity pneumonitis (Chapter 93) is rarely suspected outside of agricultural settings but is occurring far more often; the causes are likely to be microbial contaminants of work materials, but some chemicals, such as the isocyanates, may also be causal. Occupational constrictive bronchiolitis, which can cause indolent or rapidly progressive dyspnea, is seen after exposure to a variety of noxious chemicals.[3] Recently, manufacturing and inorganic chemicals have been associated with outbreaks of allergic alveolitis, and synthetic fibers and food flavorings have precipitated severe and sometimes fatal airways responses. These observations support careful investigation of the environment in all cases of adult-onset lung disease.

TABLE 19-1 COMMON OCCUPATIONAL AND ENVIRONMENTAL HEALTH CONDITIONS IN GENERAL PRACTICE

CONDITION	EXPOSURE SETTINGS	COMMENT
Asthma	Virtually any indoor or outdoor workplace	New-onset, recrudescent, or exacerbated asthma
Interstitial, parenchymal, and inflammatory lung disorders	Dusts, metals, and organic materials	All parenchymal disorders have one or more environmental causes
Cancers of the respiratory tract	Asbestos, radon, silica, combustion fumes, tars, and some metals	Smokers are more likely to be affected
Sensorineural hearing loss	Noise, metals, and solvents	High-frequency loss, especially in younger workers
Musculoskeletal disorders of trunk and limbs	Heavy or repetitive activities or postures	Cold, vibration, and work stress contribute
Upper airway irritation	Dust and fumes	More common in smokers and atopic persons
Nonspecific building-related illness	Office work	Must exclude *specific* causes
Dermatitis, allergic or irritant	Repeated exposure to unprotected skin	Work and environmental exposures should be considered in every case
Multiple chemical sensitivities	Any	Complication of adverse environmental exposure

Cancers of the Respiratory Tract

Although most carcinomas of the lung and upper airway occur in smokers, occupational exposures to asbestos, silica, and the polyaromatic hydrocarbons in particulate air pollution, diesel exhaust, pitch, and asphalt contribute to the burden, as do radon and carcinogenic metals such as chromium and nickel found in most alloys (Chapter 191). Some organic materials, such as formaldehyde, are also likely culprits. Until there is an established strategy for secondary prevention, patients with these exposures should be observed expectantly; at a minimum, extraordinary efforts should be made to control smoking in these exposed individuals. Asbestos-exposed workers—smokers or otherwise—are additionally at risk for malignant mesothelioma (Chapters 99 and 191), but other than primary prevention, the only clinical implication is awareness for early diagnosis and compassionate care for this still largely incurable industrial disease.

Fatty Liver

With the widespread use of abdominal imaging, fatty liver has been recognized as more common than previously thought (Chapter 152). This disorder is common among individuals exposed regularly to organic solvents, a possibility that should be considered at the same time that infectious, metabolic, and pharmaceutical causes are considered. Once it is suspected, whether or not other factors are also present, chemical exposure should be reduced. Improvement tends to be slow, often during a period of many months, but the risk of progression is likely to have been averted or at least diminished.

Sensorineural Hearing Loss

Aside from aging, noise is the most important cause of high-frequency sensorineural hearing loss, recognizable as early as in adolescence (Chapter 426). Hobbies such as shooting and loud music may combine with industrial and agricultural noise to accelerate hearing loss. Although it is the responsibility of employers to conduct routine audiograms and to control exposure, clinicians should test noise-exposed patients periodically and reinforce whatever control strategies may be in place at work. Exposure to metals such as lead and organic solvents may compound the risk further.

Musculoskeletal Disorders of the Upper Extremity and Trunk

The most common cause of work disability, including permanent disability, is an injury to the back (Chapter 400) or upper extremity; the annual loss to the U.S. economy from disability and health care expenditures is estimated at a staggering 1 to 2% of the gross domestic product. Repetitive, heavy, awkward, and time-pressured activities are notorious contributors, as are cold and vibration.[4] A majority of cases, however, occur in workers without extremely physical jobs, such as health care or other service workers. Although an anatomically localized lesion may be identified and specifically treated in a small fraction of cases, as in carpal tunnel syndrome (Chapter 420) or thoracic outlet obstruction, the most important modalities of care in most cases are *early recognition* and *reduction of further insult*.[5] Physical therapy and medications may hasten recovery but cannot prevent recurrences and even progression unless the causal work and avocational activities are modified. Employers, who are increasingly familiar with these ergonomic issues, share an incentive to modify tasks or work stations.

Upper Airway Irritation

Virtually any smoke, fume, dust, or chemical has potential to irritate the upper respiratory tract (Chapter 93), causing acute or chronic symptoms indistinguishable from common allergic manifestations (Chapter 249) or upper respiratory infections (Chapter 96). Although the mucosae of the eyes, nose, sinuses, and throat tend to be forgiving, recurrent episodes are extremely nettlesome and cause substantial work disability. Atopic patients and patients with frequent infections are often the most sensitive to these ubiquitous environmental insults, which must ultimately be addressed along with the symptoms themselves and secondary infections.

Dermatitis

Erythematous rashes are a common consequence of topical exposures to workplace, avocational, and household materials, including latex, plastics, and many foods (Chapter 440). Although the keys to recognition are timing and the anatomic relation to clothing, allergenic and irritating chemicals can find their way into unlikely places, such as the groin and belt lines. Specialty consultation and patch testing are warranted in intractable cases but should not supplant careful observation and history taking in most situations. Acneiform lesions and folliculitis (Chapter 440) are also often caused by chemical irritation or physical factors at work, such as heat, pressure, or friction.

Sick Building Syndrome and Nonspecific Building-Related Illness

The effort to reduce the influx of "fresh" air into buildings to save heating and air-conditioning costs has resulted in upper airway and dermal irritation as well as vague central nervous system symptoms such as headache and fatigue, occurring shortly after beginning work and clearing minutes to hours after leaving the affected building. Many occupants are typically affected, especially those who spend the most time in one place. The cause is unknown, but recent evidence suggests that microbial materials may be the most common culprits. In every instance, a search for a specific allergen or irritant is worth undertaking (Chapter 249), but the most remedial sources are poor overall ventilation and dampness in which molds fester. When the cause is remedied, most building occupants typically experience symptomatic improvement. From a clinical perspective, the major consideration is whether any more serious problem, such as asthma, may have also developed.

Multiple Chemical Sensitivities

An environmental illness as transient as a single noxious inhalation or as persistent as a protracted course of nonspecific building-related illness can initiate a cycle of similar symptoms after exposures to odors or irritants at very low levels, thereby rendering everyday tasks such as shopping or driving problematic. A patient typically complains of feeling "allergic" to everything, although there is no evidence for allergic mechanisms (Chapter 249); the cause of this vexing complication, most prevalent in women and also seen in veterans of conflicts in the Middle East, is unknown and may involve psychological as well as physiologic factors. Despite the severity of complaints, which often include fatigue, muscle pain, stridor, chest tightness, and palpitations, laboratory test results are normal; many patients will meet clinical criteria for fibromyalgia (Chapter 274). Coexistent anxiety and depression often prompt psychiatric referral (Chapter 397), but the disorder has proved relatively refractory to all treatment modalities. Sympathetic support, environmental modification as needed to provide some symptomatic relief, and candor regarding the unknown nature of the disorder are appropriate; extensive clinical investigations often serve only to reinforce the patient's "sick" role and are best avoided. Despite all efforts, the most severely affected individuals will often seek the care of alternative practitioners (Chapter 39) with compelling if unproven theories and expensive, potentially harmful remedies.

COMMON HAZARDOUS EXPOSURES IN THE WORKPLACE AND AMBIENT ENVIRONMENT

Tens of thousands of chemicals in the workplace as well as important physical and biologic hazards may be encountered in the general environment (Table 19-2). Several of these hazards are of major current concern in industrialized countries.

TABLE 19-2 COMMON HAZARDS IN THE WORKPLACE AND AMBIENT ENVIRONMENT

HAZARD	HEALTH EFFECTS OF GREATEST CONCERN	COMMENTS
Metals	Neurotoxicity, cancer	Most can be measured in blood or urine to assess dose
Organic solvents	Respiratory and dermal irritation, neurotoxicity, hepatotoxicity	Benzene and a few others have unique effects
Organohalides (e.g., DDT, PCBs)	Cancer	Ubiquitous suspect carcinogens of high population concern
Herbicides and pesticides	Rare acute neurotoxicity, unknown long-term effects	Widespread hazards of high population concern
Electromagnetic radiation	Leukemia, glioblastoma	Ubiquitous exposures with unproven effects
Particulate matter	Acute and chronic atherosclerotic cardiovascular disease	Air pollution, workplace
Mold	Allergy	High population concern regarding putative chronic effects
Mineral dusts	Cancer	Old hazards still of high concern (e.g., asbestos, silica)

DDT = dichlorodiphenyltrichloroethane; PCBs = polychlorinated biphenyls.

Metals

Exposures to lead and arsenic (Chapter 22), once commonplace in industry, are now generally controlled; concern remains highest for environmental settings, especially for children. There is now greater concern for mercury—entrained in large ocean fish worldwide—and manganese, a potent neurotoxin that is found in welding fumes and various alloys and that affects extrapyramidal and autonomic function. For most metals—manganese being a notorious exception—blood or urine tests are available to quantify a patient's burden, but these tests must be mindful of timing, the form of metal, and possible "confounders," such as the largely benign form of arsenic excreted in urine for several days after even a single shellfish meal.

Organic Solvents

These petroleum derivatives remain ubiquitous in workplace and household products. All are irritating, potentially neurotoxic, and, to varying degrees, hepatotoxic (Chapter 110). Several more serious toxins, such as trichloroethylene and *n*-hexane, are no longer widely used. Benzene and the ethers of ethylene glycol are bone marrow toxins (Chapter 165).

Organohalides

Although these complex organic pesticides and industrial materials are no longer made and sold in developed countries, their remarkable biopersistence has resulted in entrainment into everyone's fat. Worse, the dread byproduct dioxin, once associated with herbicide manufacture, has now been recognized as a predictable consequence of combustion of any chlorine-containing materials. All are suspect carcinogens, although debate remains whether this effect is limited to soft tissue sarcomas (Chapter 202)—a relationship established for dioxin—or promotes cancers more globally. Some toxicologic and epidemiologic evidence links this class of agents to type 2 diabetes mellitus and dyslipidemias.

Herbicides and Pesticides

The acute neurotoxicity and irritant properties of most herbicides and pesticides have been well studied (Chapter 110). These agents are generally well controlled, although both occupational and residential overexposures occasionally occur. In developing countries, these substances remain a widespread vehicle for both suicide and homicide.

Nonionizing Electromagnetic Radiation

Electric wires, appliances, and, notoriously, cell phones emit low-frequency electromagnetic radiation at levels far below those that cause local thermal injuries (Chapter 20). These radiations are nonionizing, but there is some

epidemiologic evidence of an increased risk of childhood leukemia with high-level exposure from household wiring and of excess brain tumors in adult workers with regular exposures. These data are difficult to interpret because study results differ according to how exposure is assessed; the only conclusion is that there is basis for concern and need for further study but not cause for widespread alarm or action other than precaution in the placement of new heavy power lines near schools and residences.

Particulate Matter

Evidence accumulated in the past decade points to the likelihood that ambient air pollution contributes measurably to the population risk of cardiovascular disease. Focus has turned from the well-established respiratory irritants—the gases sulfur dioxide and ozone—to the smallest particles, so-called $PM_{2.5}$. These particles may be laden with polyaromatic hydrocarbons from diesel exhaust, coal burning, and industrial sources, which are proinflammatory. This risk also accrues to more heavily exposed industrial workers, although it remains unclear if the risk is associated with particles of any origin or just those that evolve from combustion.

Mold

Molds are ubiquitous and long known for their unpleasant odors and potential for inducing allergic responses (Chapter 249), including asthma. Recently, concern has arisen over the potential for serious effects from various mycotoxins, long problems in veterinary medicine when domestic animals consume contaminated feed; however, a consensus panel concluded that there is no evidence of human risks beyond those well established from living or working in a moldy environment. Mold formation should be prevented wherever possible, especially in schools and offices, where molds contribute to problems with indoor air quality. Identification, with eradication of leaks and other sources of water accumulation, is key.

Mineral Dusts

Although asbestos has been largely abated, silica and human-made mineral fibers remain widely distributed in the environment. Silica (Chapter 93), present in virtually every form of "rock," is a potent cause of lung injury and cancer, so respiratory exposure should be carefully controlled in every setting. The evidence of serious risk from fibrous glass, mineral wool, and other human-made mineral fibers is less clear; probably only the finest fibers, such as slag wool, have cancer-causing potential, but many are potent dermal and upper respiratory irritants and should be well controlled for that reason alone.

SUMMARY

Occupational and environmental health problems remain prevalent, although their spectrum and nature have changed as rapidly as any in medicine and are likely to change even faster as technology, work, and knowledge continue to evolve. Physicians need not necessarily develop a large base of *facts*—themselves subject to revision frequently—but rather an *approach* that incorporates key elements and provides a foundation for efficient recognition and management of current and future clinical syndromes.

REVIEW QUESTIONS

1. A 35-year-old carpenter complains of new-onset headaches shortly after beginning a new job in a small boat-refurbishing shop. His job involves cleaning debris from the hulls of sailboats and resurfacing them. What is the most useful approach to establish whether some exposure or condition in the shop is causing his headaches?

A. Proceed as with any new headache evaluation. Then, once a diagnosis is made, explore online toxicologic databases to see if any chemicals are known to cause such a headache pattern.
B. Ask the patient to obtain a complete list of all chemicals and processes in the shop and research each to see if it can cause headaches.
C. Question the patient closely about the temporal relationship between work activities and symptoms.
D. Test the patient's blood and urine for common industrial solvents likely to be used in his work.
E. Call the employer to inquire if other workers have made similar complaints in the past.

Answer: C For the assessment of acute symptoms in relation to an environmental exposure, the history of temporal relationship between exposure and onset/cessation of symptoms is the most compelling basis for pursuit of a work connection for a new complaint. If headaches typically occur after arriving at work or starting a specific activity and are absent at other times, the physician should obtain a detailed list of chemicals or other potential culprits and explore their toxicology.

2. Which of the following is true regarding the relevance of "dose of exposure" to a workplace or environmental chemical?

A. Unlike pharmaceuticals, environmental toxins typically cause injury in susceptible people irrespective of the actual dose.
B. Unlike with pharmaceuticals, the possible doses to which a worker might be exposed at work range over many orders of magnitude.
C. Unlike with pharmaceuticals, there is no simple way of estimating exposure dose from talking to a patient; the workplace or exposure environment itself must be evaluated.
D. Unlike pharmaceuticals, environmental toxins typically affect everyone exposed in a similar way.
E. Unlike with pharmaceuticals, blood and urine levels are the mainstay for assessing exposure dose to chemicals.

Answer: B For drugs and toxins, dose matters. What differs is the sheer number, probably 100,000 or more, of different chemicals and the enormous range of possible exposure doses, from trivial parts per billion or trillion in a well-controlled environment to gram quantities in an unventilated workplace or in an accidental release. However, as noted in the text, strong inference about the range of exposure dose can be made from talking to the patient; directly measuring the environment and biomarkers of exposure is rarely the first-line approach. As with drugs, idiosyncratic responses are common, and no two people respond alike.

3. Which of the following is true regarding occupation-related asthma?

A. Nonatopic individuals with previously normal respiratory health may develop de novo sensitivity to one of hundreds of workplace proteins, metals, or other chemicals.
B. Smokers and atopic individuals are the ones most likely to develop airway reactions at work. Cough or wheeze in the presence of one or more such risk factors demands *increased* vigilance about workplace exposures.
C. Workplace factors cause or exacerbate asthma in up to 20% of adult-onset asthma cases.
D. A and C
E. A, B, and C

Answer: E Work exposures commonly cause airway lability in susceptible individuals, sometimes by primary sensitization in atopic or nonatopic men and women and sometimes by irritating already abnormal airways in smokers and patients with preexisting airway disease. Most studies estimate that almost one in five newly symptomatic adult asthmatics has an occupational or environmental cause, so this possibility must always be explored because an overlooked and preventable exposure may lead to lifelong, irreversible injury.

4. A 60-year-old woman is admitted to the hospital with new onset of a large pleural effusion and incapacitating chest pain. What is the best approach to determine if a work exposure may have been involved?

A. Perform a detailed occupation and environmental history of *current* exposures on admission to identify a possible cause for malignant or nonmalignant disease consistent with the presentation, such as asbestos.
B. Perform a detailed occupation and environmental history of *past* exposures on admission to identify a possible cause for malignant or nonmalignant disease consistent with the presentation, such as asbestos.
C. Proceed with the evaluation as you would for any patient with the observed constellation of signs and symptoms. Take a detailed environmental history of current and past exposures *after* a pathologic diagnosis has been made, focusing on established causes of that diagnosis, for example, lung cancer.
D. After the evaluation, ask the laboratory to analyze surgical and other specimens for evidence of fibers or metals that are known to cause the patient's diagnosed condition.
E. After the diagnosis is made, seek information from the local health department or similar agencies about the occurrence of similar cases in the area because patients are unlikely to recall what they were exposed to years before.

Answer: C In the assessment of a new-onset chronic disease, it is not efficient to take an exhaustive history of either current or former exposures as the evaluation will quickly reveal a clear target (diagnosis) on which to focus. Although recognition of a prominent work exposure, such as asbestos, might make the possibility of malignant mesothelioma more likely in this case, it is still necessary to make a pathologic diagnosis before worrying about its cause. This approach is in contrast with the approach to new onset of acute or recurring symptoms (question 1). D and E are important in some cases, but the first and most direct approach is to inquire whether the patient may have been exposed to the (invariably) small number of substances known to cause the just-diagnosed condition. These lists can easily be found in reference texts or online search tools (e.g., "occupational causes of lung cancer").

5. Which of the following is true of musculoskeletal disorders among working-age patients?

A. Because these disorders are most often associated with nonspecific findings on examination or imaging studies, they rarely lead to significant dysfunction or disability.
B. Now that most work in developed economies is less physical, musculoskeletal disorders have become relatively rare.
C. The best approach to prevent long-term disability is early recognition, intensive evaluation, and definitive treatment where possible.
D. Assessment and modification of offending work activities are more important in the long run than is a definitive anatomic diagnosis.
E. When a musculoskeletal disorder is recognized, the best way to establish whether it is related to work activity is to visit the workplace or to call the employer.

Answer: D Musculoskeletal disorders remain extremely common and extremely disabling even in highly developed economies and in jobs—like health care, food service, and education—that are not intensely physical. The key to diagnosis is the relationship between physical activities at work, which the patient can easily demonstrate to the physician, and the pattern of symptoms and signs. Intervening in the work by job modification or change is far more valuable in the long run than finding a drug or surgery to control the symptoms, which often recur when the patient returns to the old environment and tasks.

RADIATION INJURY

DAVID J. BRENNER

IONIZING RADIATION

DEFINITION

Ionizing radiations include x-rays, gamma rays, beta particles, alpha particles, and neutrons. Unlike non-ionizing radiations, including radio waves, microwaves, infrared, visible light, and ultraviolet (UV) radiations, these radiations have enough energy to knock electrons out of atomic or molecular orbits, thereby breaking chemical bonds in biomolecules such as DNA.

A key difference among the various ionizing radiations is their ability to penetrate matter (Fig. 20-1). For example, alpha particles have very limited range, measured in micrometers. Because alpha particles cannot penetrate skin, their health significance is entirely in the context of internal exposure by inhalation or ingestion of alpha-emitting radioactive materials. Beta particles, which have intermediate ranges, can typically be stopped by a piece of paper. By contrast, x-rays, gamma rays, and neutrons are highly penetrating and are hard to shield.

Ionizing radiations are emitted by radioactive materials, which can either be naturally occurring or can be man-made, using machines such as nuclear reactors. The amount of ionizing radiation emitted by a radioactive material is determined by its activity, measured in becquerels (1 Bq = 1 radioactive disintegration/second) or Curies (Ci).

Radioactivity should be distinguished from absorbed dose, which is a measure of how much ionizing energy is actually absorbed by a structure of interest, such as a person or an organ. The basic measurement unit of absorbed dose, which is the energy deposited per unit mass, is the Gray (1 Gy = 1 J/kg). *Equivalent dose* takes into account the fact that not all types of radiation are equally effective, *effective dose* takes into account the fact that not all organs in the body are equally sensitive to ionizing radiation, and *collective dose* is a measure of the effective dose delivered summed over a whole exposed population (Table 20-1).

EPIDEMIOLOGY

Radiation exposure can come from natural sources, therapeutic or diagnostic medical exposures, or accidental exposures to individuals or to large populations. Natural sources and radiologic examinations are the major contributors to the overall collective radiation dose to the U.S. population (Fig. 20-2).[1]

Natural Sources of Ionizing Radiation

The largest naturally occurring source of radiation is from radon gas, which is an alpha-particle emitter. Radon is a constituent component of all rocks, particularly granite-type rocks. Radon is a member of a chain of radioactive elements that starts with naturally occurring uranium and radioactively decays from one element to the next; uniquely in this chain of elements, radon is a gas, which can emerge from the ground and result in high levels in the basement and higher floors of houses. Long-term exposure to radon gas can cause lung cancer because emitted alpha particles in the lung can damage cells in the bronchial epithelium. The three other main sources of naturally occurring radiation exposure are from terrestrial exposure (gamma rays emitted from naturally occurring radioactive materials in the ground), from space radiations (mainly intergalactic cosmic rays that penetrate through the atmosphere), and internal radiation (from naturally occurring radioactive elements in the body, such as potassium-40).

Medical Exposures

The single largest source of medical exposure is computed tomography (CT), which on average contributes about 25% of the collective dose to the U.S. population. This source of exposure is recent because CT has been commonly used only since the 1980s. Now, however, about 75 million CT scans are performed annually in the United States. In addition to CT, nuclear medicine, interventional fluoroscopy, and conventional radiography together constitute about 25% of the overall collective dose to the U.S. population.

Radiologic Accidents

Since the widespread introduction of nuclear power plants, major radiologic accidents have become an intermittent, although rare, source of radiation

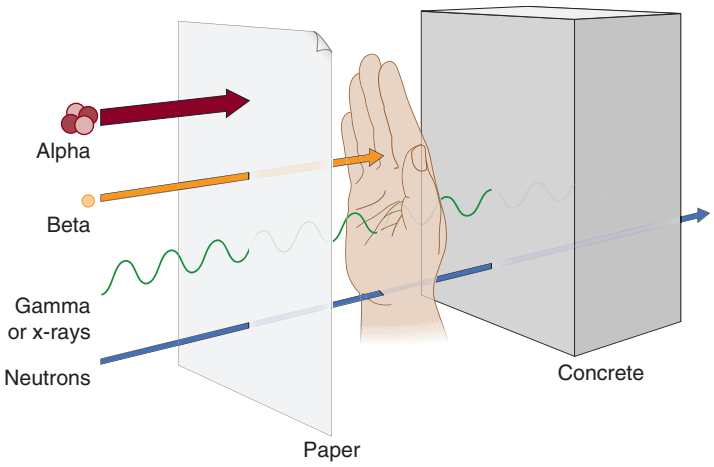

FIGURE 20-1. Schematic illustrating the relative ranges of alpha particles, beta rays, x-rays or gamma rays, and neutrons as they penetrate through matter.

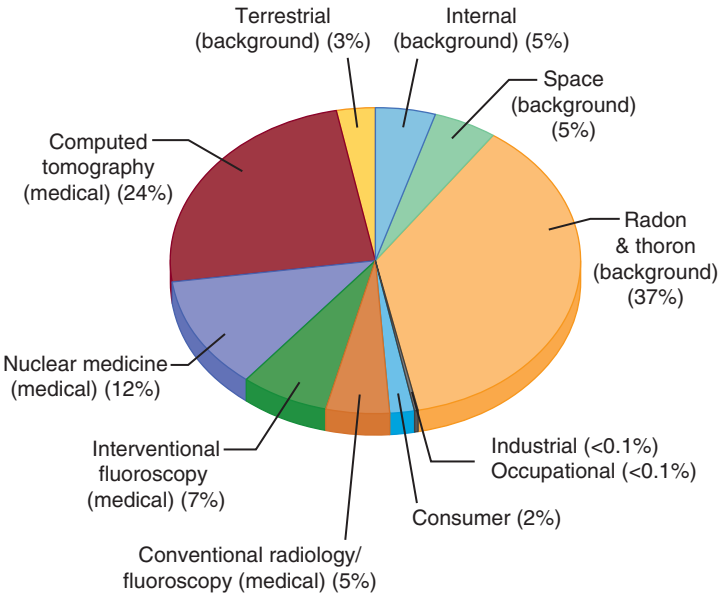

FIGURE 20-2. The major sources of radiation exposure to an average individual in the United States. (From Hall EJ. *Radiobiology for the Radiologist*. 7th ed. Philadelphia: Lippincott Williams & Wilkins; 2012.)

TABLE 20-1 STANDARD QUANTITIES AND UNITS ASSOCIATED WITH EXPOSURE TO IONIZING RADIATION

QUANTITY	DEFINITION	UNITS
Absorbed dose	Energy per unit mass	Gray (Gy)
Equivalent dose	Average dose × radiation-type-specific radiation weighting factor	Sievert (Sv)
Effective dose	Sum of equivalent doses to all exposed organs, each multiplied by an appropriate organ relative sensitivity factor	Sievert (Sv)
Collective dose	Sum of effective doses to a population of exposed individuals	Person-Sv

exposure. The accidents at Chernobyl in 1986 and at Fukushima in 2011 released far more radioactivity than any other accidents (Table 20-2).

Radiologic Terrorism

In the broadest of terms, two different types of such threats exist, one from an improvised nuclear device and the other from a radiologic dispersal device, sometimes called a *dirty bomb*.[2] The two are very different in terms of their potential consequences and also their likelihood of occurrence.

TABLE 20-2 ESTIMATED RELEASES OF RADIOACTIVE IODINE AND RADIOACTIVE CESIUM FROM THE FOUR HISTORICALLY BIGGEST NUCLEAR POWER PLANT ACCIDENTS

	^{131}I (TBq)	$^{137/134}$Cs (TBq)
Windscale, 1957	750	20
Three Mile Island, 1979	1	0.000001
Chernobyl, 1986	1,800,000	110,000
Fukushima, 2011	~500,000	~20,000

The consequences of exploding an improvised nuclear device, perhaps similar to those detonated at Hiroshima or Nagasaki, although more likely exploded at ground level, would be devastating in terms of loss of life and major injuries. For example, a 20-kT daytime surface improvised nuclear device explosion in midtown Manhattan might involve 2.2 million people exposed to high radiation doses, of whom perhaps only 1.6 million might survive.

By contrast, the consequences of exploding a radiologic dispersal device or dirty bomb, dispersing what could be very small or very large amounts of radioactive material, would likely involve a relatively small spatial area in which individuals are significantly exposed, as well as a much larger area in which individuals are exposed to very low levels of radioactivity. The significance of a dirty bomb depends on the amount of radioactivity in the device and the efficiency with which the explosion aerosolizes and disperses the radioactive material. Of course, the consequences of a radiologic dispersal device extend beyond health effects and could potentially involve large-scale social and economic disruption.[3]

PATHOBIOLOGY

Ionizing radiation can both mutate cells and kill them. The key initial damage site is a DNA double-strand break, although other types of damage are possible. This strand break is generally repaired by a variety of mechanisms, the most important of which is nonhomologous end rejoining. Imprecise nonhomologous end rejoining can lead to small mutations, whereas double-strand break misrepair (i.e., the wrong ends of breaks being rejoined to each other) can lead to chromosomal translocations, inversions, and telomere fusions.

Although chromosomal translocations, inversions, and point mutations are typically nonlethal lesions, such radiation-induced chromosomal aberrations can be the initial lesions associated with carcinogenesis. For example, the initial event in many hematopoietic cancers (Chapters 183 and 184) is often a recurrent translocation, which in turn results in the fusion of genes located at the translocation breakpoints. Radiation-induced point mutations and deletions also are often associated with loss of heterozygosity in tumor suppressor genes.

Misrepair of double-strand breaks can also induce dicentric chromosome aberrations and centric rings (Chapter 181), which are generally lethal lesions that cause reproductive cell death in which a cell loses its ability to divide. A second, quite different mechanism of radiation-induced cell death is apoptosis, or programmed cell death that, for example, is important after radiation exposure of hematopoietic cells and jejunal crypt cells.

CLINICAL MANIFESTATIONS

The consequences of radiation exposure are dose dependent and are also dependent on whether the exposure is to the whole body or only part of the body. After high doses of whole-body exposure, the major consequences are acute radiation syndromes, which may be fatal. After high doses of partial-body exposure, such as after radiotherapy, the consequences are highly organ specific. These high-dose tissue effects are deterministic, meaning that above a certain dose threshold, the probability of the effect rapidly increases to 100%, with the severity of the effect increasing with increasing dose. By contrast, the major concern at lower doses is with stochastic effects, in which there is no dose threshold, and it is the probability of the effect that increases with increasing dose. The major example here is radiation-induced cancer.

Acute Radiation Syndromes

The radiation dose needed to kill mitotically active dividing cells is far less than the dose needed to remove the functioning ability of differentiated cells. As a result, acute radiation syndromes generally relate to the failure of

precursor cells to provide replacements for functional cells within an organ, when the latter need replacement. Acute radiation syndromes typically progress through four stages: prodromal, clinical latency, manifest illness, and recovery or death.

Prodromal Stage

Prodromal (early) symptoms occur shortly after irradiation, with the radiation dose determining the severity, duration, and onset. Typical prodromal symptoms include nausea, vomiting, anorexia, fatigue, diarrhea, abdominal cramping, and dehydration. At very high doses, these symptoms can appear within a few minutes of exposure; but at somewhat lower doses, they may not appear for many hours, if at all.

Latency Period

After the prodromal stage, a latency period typically precedes manifest illness. This delay occurs because the subsequent syndromes (hematopoietic and gastrointestinal) involve the failure of relevant tissues to self renew, and manifest illness does not occur until after the typical cellular turnover times in these tissues.

Manifest Illness

The *hematopoietic syndrome* results from whole-body or significant partial-body exposure to 3 to 9 Gy. At these doses, radiation kills some or all of the mitotically active hematopoietic precursor cells. Symptoms then result from lack of circulating blood elements some 4 to 8 weeks later as circulating cells die off and are not replaced. At this point, the hematopoietic syndrome may manifest as infections and possible hemorrhage, impairment of immune mechanisms, and potentially multiple-organ failure.

The *gastrointestinal syndrome* usually occurs after whole-body or significant partial-body exposure of about 8 Gy and above. These doses lead to death of intestinal stem cells in the regenerating crypts. Symptoms then result when differentiated cells of the villi are naturally sloughed off, but stem cells are unable to produce new cells, thereby leading to depopulation of the epithelial lining of the gastrointestinal tract. After a latency period of about 7 days, loss of, or significant shortening of, the villi on the intestinal epithelium leads to bacterial growth and increased risk for sepsis. Common symptoms include anorexia, nausea, vomiting, prolonged bloody diarrhea, abdominal cramps, dehydration, and weight loss. Should death occur, it is typically 7 to 10 days later.

At extremely high radiation doses, death is typically from the *cerebrovascular syndrome* within a few days after exposure. The cause of death is believed to be because changes in permeability of small blood vessels in the brain lead to cerebral edema.

Organ-Specific Late Effects after Radiotherapy

Iatrogenic organ-specific late effects follow quite predictably after targeted radiation therapy in which the organ in question is irradiated, although the severity of the response is less predictable. These tissue effects can be divided into global organ responses and focal responses, in which a particular part of the organ is differentially irradiated (Table 20-3).

As one example, significant radiation exposure to the heart increases the risk for subsequent major heart disease. These risks have been most notable in women who have had radiotherapy for left-sided breast cancer (Chapter 198),[4] patients treated with mantle radiation for Hodgkin lymphoma (Chapter 186), and some patients treated for lung tumors adjacent to the heart.[5] The effects to the heart can be wide ranging, including to the coronary arteries, the myocardium, the heart valves, and the pericardial sac. The increased risk, which is proportional to the cardiac dose, begins within a few years after exposure and continues throughout life. These radiation risks appear to be multiplicative of the natural background cardiac risks, so patients with preexisting cardiac risk factors are likely to have greater absolute increases in their risk for radiation-induced cardiac disease.

At lower radiation doses, good evidence indicates that atomic bomb survivors have an increased lifetime risk for heart disease as well as an increased risk for stroke.[6] Among atomic bomb survivors, radiation-induced heart disease and stroke are estimated to account for about one third of the radiation-induced excess deaths compared with cancers.

TABLE 20-3 TYPICAL ORGAN-SPECIFIC DETERMINISTIC LATE EFFECTS AFTER HIGH-DOSE RADIOTHERAPY

ORGAN	LOCALIZED END POINT	GLOBAL END POINT
Brain, cranial nerves	Focal weakness, vision loss	Neurocognitive deficit
Lung	Bronchial stricture	Shortness of breath
Heart	Coronary stenosis	Pericarditis, cardiomyopathy
Bladder	Bleeding	Urinary frequency, diarrhea
Bowel	Ischemia, bleeding	Enteritis

Adapted with changes from Rubin P, Constine LS, Marks LB, eds. *ALERT—Adverse Late Effects of Cancer Treatment. Vol. 1: General Concepts and Specific Precepts.* Heidelberg: Springer; 2014.

Stochastic Effects of Radiation

In contrast to the deterministic organ-based effects of radiation, ionizing radiation also produces stochastic effects, whereby the severity of the disease is not dose dependent, but the probability of an effect increases with increasing dose. These effects are largely due to radiation-induced mutations of target cells, as opposed to cell killing, with by far the most important effect being radiation carcinogenesis. Other potential radiation-induced stochastic health effects include deleterious radiation-induced genetic effects to subsequent generations.

Radiation Carcinogenesis

In general, radiation acts as a multiplier of natural background cancer rates, although there are exceptions, such as radiation-induced breast cancer, in which the radiation risks are largely independent of the natural background rates, and prostate cancer, which generally is not a radiogenic tumor. Most radiation-induced cancers occur many years after radiation exposure, typically in the same "cancer-prone" years (about 55 to 75 years of age), as do naturally occurring cancers. Exceptions include radiation-induced hematopoietic cancers and radiation-induced thyroid cancers, both of which typically occur within a few years of radiation exposure. Sensitivity to radiation-induced cancer is age dependent, with people exposed at younger ages having higher lifetime cancer risks.

Most of what is known quantitatively about the radiation-induced risks for cancer comes from studies of atomic bomb survivors, who had measurable increased subsequent risks for cancer.[6] At low radiation doses, for example, below 0.1 Gy, epidemiologic studies are difficult to perform and interpret because it is difficult to quantify a small extra risk for cancer above the natural human lifetime cancer risk of about 40%. More recently, large-scale epidemiologic studies in children who received CT scans suggest small but statistically significant increased risks for radiation-induced cancer, at least down to the radiation doses relevant to CT scans.[7,8]

Radiation Cataractogenesis

Ionizing radiation induces cataracts (Chapter 423) with a probability, severity, and latency related to the radiation dose.[9] Studies of atomic bomb survivors, Chernobyl cleanup workers, astronauts, and radiologic technicians have all shown increased incidence of cataracts, even at radiation doses below 1 Gy. Radiation cataractogenesis is a result of radiation damage or killing of dividing cells in the lens. Because there are essentially no mechanisms in the lens for removal of damaged cells, the resulting nontranslucent lens fibers migrate toward the posterior pole of the lens, where they represent the first stage of a cataract. Posterior subcapsular cataracts are less common than nuclear or cortical cataracts in the general population but are the type most commonly associated with ionizing radiation.

DIAGNOSIS

The diagnosis of radiation injury can be considered in two different contexts. The first context is when the radiation dose is not known, and the goal is to estimate the dose that was delivered in order to optimize treatment. Examples include accidents and radiologic terrorism scenarios. The second context is when the radiation dose is known, in particular after radiotherapy. Here the sequelae (see Table 20-3) are predictable, but the timing and the severity of the injury are less predictable.

Radiation Biodosimetry

For an individual exposed to a large whole-body radiation dose, the first critical task is to estimate the radiation dose that the individual received, because different syndromes (hematopoietic, gastrointestinal, cerebrovascular) are associated with different radiation dose ranges. The technique for estimating exposures to individuals is known as *radiation biodosimetry*. In this diagnostic process, a small amount of a body tissue, such as blood or urine, is analyzed,

and dose-dependent end points in the sample are measured to provide an estimated dose. The most common end point, which is chromosomal aberrations in blood samples, can now be assessed by high-throughput technologies.[10] Other practical radiation-dose dependent assays include gene expression in blood or induction of metabolites in urine.

Post-Radiotherapy Sequelae

Deterministic radiation-induced organ syndromes are seen at reasonably predictable intervals after radiation therapy. For example, radiation pericarditis (Chapter 77) can develop during treatment or months to years later, initially with an effusion and progressing to pericardial constriction. Radiation enterocolitis (Chapter 140) can develop 6 to 12 months after radiation doses of 40 to 60 Gy for prostate cancer or gynecologic malignancies. Radiation-induced pulmonary injury can be detected in up to 50% of patients who receive thoracic radiation therapy, but only a minority of them will develop clinical symptoms (Chapter 94). In addition, the majority of all radiotherapy patients experience acute skin or mucosal toxicity, in particular radiation dermatitis, oral mucositis, and xerostomia.

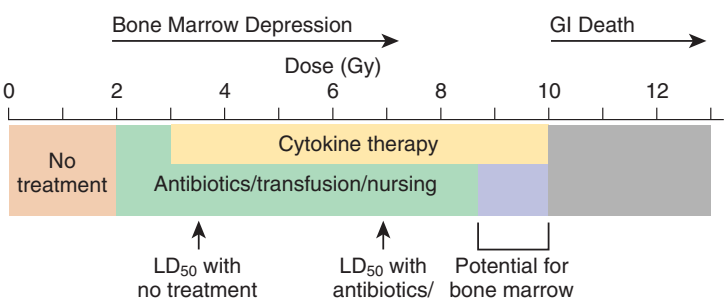

FIGURE 20-3. Schematic recommended treatment for acute radiation syndromes, as a function of the estimated dose that the individual received. Note the very narrow dose window for which bone marrow transplantations are potentially useful. (Adapted with changes from Hall EJ. *Radiobiology for the Radiologist*. 7th ed. Philadelphia: Lippincott Williams & Wilkins; 2012.)

TREATMENT Rx

Whole-Body Exposure Syndromes

For exposures below 2 Gy, no immediate treatment is needed (Fig. 20-3). For the hematopoietic syndrome, two primary treatment approaches are designed to reduce red blood cell depression, by using transfusions and cytokine therapy, and to minimize infection, by using antibiotics and possibly barrier nursing. Antibiotics and appropriate nursing care can raise the human LD_{50} (the dose at which 50% of exposed individuals die) from about 4 to 6 Gy, and the addition of human granulocyte colony-stimulating factor (e.g., filgrastim, 5 µg/kg daily for up to 2 weeks, subcutaneously or by IV infusion) may increase the LD_{50} to about 9 Gy.

The role of bone marrow transplantation in treating individuals with the hematopoietic syndrome is probably quite limited at doses less than about 9 Gy. In the aftermath of the Chernobyl accident, for example, 13 individuals underwent bone marrow transplantation, and three deaths were directly attributed to the sequelae of the procedure in patients in whom the transplantation was not indicated based on their exposure. Conservative treatment regimens, including antibiotics, cytokine therapy, transfusions, and nursing are clearly effective, but current treatment options are very limited at doses above about 10 Gy, when the gastrointestinal syndrome becomes the dominant cause of death.

Radiotherapy Sequelae

For radiotherapy-induced dermatitis, mucositis, and xerostomia, treatments include topical agents for dermatitis (Chapter 438), analgesics for mucositis, and saliva substitutes for xerostomia. Beyond dermatitis, mucositis, and xerostomia, radiation-induced deterministic tissue effects are typically treated in the same way as their non-radiation-induced counterparts. For example, the treatment of radiation-induced coronary artery disease is no different than the approach to coronary diseases in general (Chapters 71 to 74). However, the management of acute and chronic gastrointestinal symptoms after radiotherapy requires a more specialized approach because of the risk for local stricture (Chapter 142).[11]

PREVENTION

Countermeasures after Radiologic Accidents or Terrorism

Three FDA-approved pharmaceuticals can limit the radiation dose caused by exposures to specific radioisotopes: potassium iodide for radioactive iodine, Prussian blue for radioactive cesium or thallium, and diethylenetriamine pentaacetate (DTPA) for plutonium, americium, or curium. Although these pharmaceutical countermeasures can limit the organ doses and therefore the health consequences produced by these specific radioisotopes, they cannot be used to treat any of the adverse clinical effects caused by them.

The administration of potassium iodide (KI), which contains nonradioactive iodine, saturates the thyroid with nonradioactive iodine and thereby prevents radioactive iodine being absorbed into the thyroid, where it can cause thyroid cancer (Chapter 226). The protective effects of KI last about 24 hours, so it should be taken daily (130 mg for adults, 65 mg for children >3 years of age, 32 mg for children 1 to 3 years of age, 16 mg for infants) while there is a likelihood of exposure.

Prussian blue (ferric hexacyanoferrate [II]) binds cesium in the gastrointestinal tract and limits its reabsorption into the blood stream, thereby reducing the biologic half-life of cesium in the body from about 110 days to about 30 days and limiting the organ toxicities that it produces. The recommended dose of Prussian blue is 3 g orally three times daily for adults and 1 g orally three times daily for children 2 to 12 years of age, for a minimum of 30 days.

DTPA is a chelating agent that binds to radioactive plutonium, americium, and curium, thereby decreasing their persistence in the body. DTPA comes in two forms, Ca-DTPA and Zn-DTPA, with the calcium form considered more effective over the first 24 hours of exposure, and the zinc form preferable at later times, although both are effective over several weeks. They are administered intravenously (or with a nebulizer), with a daily intravenous dose of 1 g for adults and 14 mg/kg for children younger than 12 years.

Medical Imaging

Because CT is such a superb diagnostic tool and because individual CT risks are small, the nearly 90 million CT scans performed annually in the United States generally provide far more benefits than risks. However, organ doses from CT are typically far larger than those from conventional radiographic examinations, so CT should operate under the principle of using as low a dose as reasonably achievable. The first opportunity is to reduce the radiation dose per scan, so-called optimization, with improved technology. The second opportunity is justification—making sure that all CT scans are clinically justified. A substantial fraction of CT scans could potentially be replaced by other modalities, such as magnetic resonance imaging for some head examinations[12] and selective use of ultrasound for diagnosing appendicitis.[13] In addition, some CT scans could be avoided entirely by avoiding CT scans when imaging is not clinically necessary.

Radiation Therapy

Amifostine (200 mg/m^2 given intravenously daily, before each fraction of radiation therapy) has been approved by the U.S. Food and Drug Administration (FDA) for minimizing radiotherapy-associated xerostomia, but its use has been limited by significant toxicity. Several drugs have been designed to mitigate or treat the damage caused by radiation therapy, particularly to the mucosal barrier. Palifermin, which is a recombinant human keratinocyte growth factor, is FDA approved (60 µg/kg/day administered as an IV bolus injection for 3 consecutive days before therapy and 3 consecutive days after therapy for leukemia or lymphoma) to decrease the incidence or duration of severe oral mucositis.

NON-IONIZING RADIATION INJURY

Ionizing radiations uniquely have sufficient energy to cause DNA strand breaks, which in turn can lead to cell killing and mutations. By contrast, non-ionizing radiations, such as radio waves, microwaves, infrared radiation, and visible light, do not have sufficient energy to break DNA strands and have not been associated with health hazards. One exception is UV radiation, which is clearly a mutagen and a carcinogen. A second possible exception is radiofrequency radiation, although in this case the epidemiologic evidence and mechanistic considerations do not provide strong evidence of health risks.

Ultraviolet Radiation

UV radiations, which are part of the non-ionizing electromagnetic spectrum, cover a wavelength from about 150 to 400 nm (intermediate between visible light and x-rays). In turn, these UV wavelengths are subcategorized as UVA (400 to 320 nm), UVB (315 to 280 nm), and UVC (280 to 150 nm).

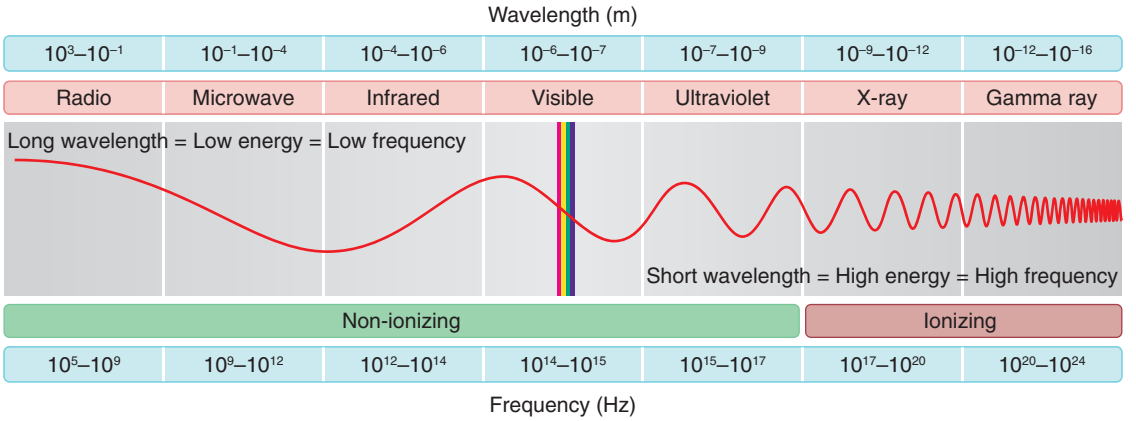

FIGURE 20-4. The electromagnetic spectrum.

Sunlight is by far the largest source of UV radiation to humans. Because of filtering in the atmosphere, about 95% of the UV spectrum that reaches the earth's surface is UVA, the remainder is nearly all UVB, and almost no UVC penetrates the ozone layer to reach the earth. Other sources of UV exposures include tanning beds and booths. Industrial exposures include welding arcs, plasma torches, germicidal and blacklight lamps, electric arc furnaces, hot-metal operations, mercury-vapor lamps, and some lasers.

PATHOBIOLOGY

UV radiations do not penetrate deeply into human tissues, so the injuries they cause are principally to the skin and eyes. The biologic effects of UV radiation are primarily attributable to its absorption in DNA, where pyrimidine dimers and their products are produced. These products are generally very efficiently removed, primarily through nucleotide excision repair but also through base excision repair, but errors in these repair processes ultimately can result in mutations. Although most UV radiation in sunlight is UVA, UVB is much more efficiently absorbed by nucleic acids, and most of the biologic effects of sunlight are associated with UVB.

The damaging effects of UV radiation are exacerbated in patients who have underlying defects in nucleotide excision repair. For example, studies of patients with xeroderma pigmentosum (Chapter 436) have provided key evidence of the link between UV light and skin cancer. In addition, the effects of UV are often enhanced in patients who are taking medications that contain photodynamic agents, such as tetracyclines, fluoroquinolones, nonsteroidal-anti-inflammatory drugs, diuretics, statins, phenothiazines, thioxanthenes, and antifungals. Such drug-related phototoxic reactions typically resolve after the drug is discontinued.

CLINICAL MANIFESTATIONS

The major acute effects of UVB exposure are sunburn and erythema, whereas UVA exposure is rarely the direct cause of sunburn. All ultraviolet radiations are well-established skin carcinogens (Chapter 203). Squamous cell carcinomas and basal carcinomas are typically associated with multiple or chronic exposures to sunlight, whereas melanoma is linked primarily to episodes of acute sunburn. Lighter skinned individuals, whose skin and eyes contain less melanin, are more prone to all UV effects because melanin acts as a photoprotector. Acute exposures of the eye to UVB (Chapter 423) can cause "welder flash" (photokeratitis), and chronic exposures are associated with cataracts as well as pterygium.

PREVENTION

Excessive exposure to sunlight or other sources of UV radiation should be avoided, especially in fair-skinned individuals. UV radiation–screening lotions or creams and UV radiation–blocking sunglasses should be used when appropriate.

During significant exposure to sunlight, it is important to use a broad-spectrum sunscreen that provides protection from UVB as well as UVA. Standard recommendations are use of sunscreen with a sun protection factor (SPF) of 30, with reapplication at least every 2 hours. Likewise, sunglasses should be rated to block 99% or 100% of UVB and UVA radiation.

Radiofrequency Radiation

Radiofrequency radiations are also part of the non-ionizing electromagnetic spectrum (Fig. 20-4). Examples are radiation emitted from mobile phones (800 MHz to 2 GHz) and radiation from electric power lines (50/60 Hz). Biologic studies of low-level radiofrequency exposure have shown slightly increased heating but no increase in DNA damage.[14]

Numerous epidemiologic studies have focused on the effects of electric power lines. Although some early studies showed an association between the proximity of residence to high-voltage power lines and the risk for childhood leukemia, these early studies have generally not proved repeatable.[15] Likewise, numerous studies of a possible relationship between cell phone use and head or neck tumors have not shown a convincing link. A recently launched prospective European study will follow 290,000 adult cell phone users over a 20-year period.

BIOTERRORISM

MARK G. KORTEPETER AND THEODORE J. CIESLAK

The likelihood that an individual physician would be called on to respond to a bioterror or biocrime incident is remote, but primary care physicians play critical roles as the point of entry into the medical system and as consultants for emergency services for any potential victims. Therefore, it is important for internal medicine physicians to be familiar with potential epidemiologic clues that an attack has occurred, general clinical aspects of agents considered to be the greatest threats, and how to alert the appropriate public health resources if they suspect an event.

HISTORY

Over centuries, biologic pathogens have repeatedly been used as weapons of warfare, ranging from tossing a dead animal carcass or feces into an adversary's water supply to releasing infectious agents by aerosol spraying.[1] Although biologic weapons can be used by governments as agents of warfare, a bigger concern now is their use by terrorists on civilian populations.

The opinions and assertions contained herein are the private views of the authors and are not to be construed as official or as necessarily reflecting the views of the Department of Defense, the United States Army, or the U.S. Government.

EPIDEMIOLOGIC CLUES

As with any other outbreak, the response to a potential act of bioterrorism relies on basic public health fundamentals. Although no single feature can be considered definitive, several features should raise the suspicion of an unnatural event (Table 21-1).

Victims of a chemical or conventional weapon release would likely become ill shortly after a release or explosion, whereas release of a biologic weapon would initially be silent because of its incubation period, with victims likely presenting for care in a delayed fashion to different care providers, dispersed in space and time. One way in which a bioterror attack might differ from a natural outbreak is in the unusual presentation of illness. For example, a disease that typically occurs on the skin or causes gastrointestinal illness might instead be manifested with respiratory features (e.g., anthrax, plague). Another clue could be illnesses that are unresponsive to standard therapies because of an unusual antibiotic sensitivity profile. Suspicion should also be raised by finding a disease outside the location or season in which it is typically found.

TABLE 21-1 EPIDEMIOLOGIC CLUES OF A BIOWEAPON ATTACK

A large outbreak with a similar disease or syndrome, especially in a discrete population
Many cases of unexplained diseases or deaths
More severe disease than expected for a specific pathogen or failure to respond to standard therapy
Unusual route of exposure for a pathogen, such as the inhalational route for diseases that normally occur through other exposures
A disease that is unusual for a given geographic area or transmission season, especially in the absence of a competent vector
Multiple simultaneous or serial epidemics
A single case of an uncommon agent (smallpox, some viral hemorrhagic fevers, inhalational anthrax, pneumonic plague)
Unusual strains or variants of organisms, or antimicrobial resistance patterns different from those known to be circulating
A similar or exact genetic type among agents isolated from distinct sources at different times or locations
Higher attack rates among those exposed in certain areas, such as inside a building after an indoor release, or lower rates in those inside a sealed building with an external release
Outbreaks of the same disease occurring simultaneously in noncontiguous areas
A zoonotic disease occurring in humans but not in animals
Direct evidence or intelligence of a release (equipment, munitions, tampering) or other potential vehicle of spread (spray device, contaminated letter)
A downwind pattern of casualty location

Modified from Dembek ZF, Alves DA, Cieslak TJ, et al. USAMRIID's Medical Management of Biological Casualties Handbook, 7th ed. September 2011. Found at www.usamriid.army.mil under reference materials tab. Accessed January 29, 2015.

AGENTS OF CONCERN

Among the myriad human infectious pathogens, a relatively small number possess the requisite properties to be considered potential weapons that could cause widespread disease, so-called weapons of mass destruction (Table 21-2). These agents typically remain stable in aerosol, which allows their relatively efficient spread, potentially over a large population.

ANTHRAX

EPIDEMIOLOGY

Anthrax, caused by infection with the gram-positive bacillus *Bacillus anthracis* (Chapter 294), is a worldwide scourge of herbivores. Most human cases have had direct contact with infected animals or their hides, hair, bone, or skins, although a recent outbreak occurred among injection drug users in the United Kingdom. Endemic areas tend to include underdeveloped parts of sub-Saharan Africa and Southeast Asia, where humans interact closely with animals that have not been vaccinated. Sporadic cases occur in the United States, typically along the trails of the historic cattle drives in the central plains. Animals are typically infected while grazing in areas contaminated with anthrax spores, which can survive in the soil for decades and are stable in a desiccated powder form. Although most cases worldwide are cutaneous, the spore form of the organism can be milled into the ideal particle size (2 to 6 μm) for infecting the lung and causing inhalational disease.

PATHOBIOLOGY AND CLINICAL MANIFESTATIONS

Exposure to spores can occur through a break in the skin, through the gastrointestinal tract, or by inhalation. Spores are taken up by macrophages and replicate in the local skin, or they can be transported to the regional lymph nodes in the gastrointestinal tract or lungs. While replicating, the bacilli secrete lethal toxin, which causes local necrosis, and edema toxin, which causes significant local edema. In untreated or unrecognized disease, the organism can cause bacteremia, systemic toxemia, and death.

Cutaneous anthrax can be readily recognized by the astute clinician on the basis of two clinical manifestations caused by its toxins: a black eschar, from which anthrax gets its name (from the Greek *anthrakis*, for coal), and surrounding edema that is out of proportion to the size of the lesion. The lesion starts as a papule that becomes a vesicle and eventually develops a central, black, necrotic area. Although this form of disease is readily treatable, it can lead to a 20% case-fatality rate if it is not recognized and treated appropriately. Gastrointestinal anthrax, which occurs after ingestion of infected, undercooked meat, is much more difficult to recognize and can have a case-fatality rate of 50% or more. Afflicted individuals develop fever, abdominal

TABLE 21-2 CENTERS FOR DISEASE CONTROL AND PREVENTION CATEGORY A BIOTERROR AGENTS

DISEASE (AND AGENT)	DIAGNOSTIC ASSOCIATIONS	WEAPONIZATION RATIONALE	TREATMENT (SEE TEXT FOR DETAIL)
Anthrax (*Bacillus anthracis*; Chapter 294)	Hemorrhagic mediastinitis	Highly lethal inhalational disease; stable spores survive desiccation; can be formulated as aerosol	Ciprofloxacin (400 mg IV q12h) or doxycycline (100 mg IV q12h) + clindamycin (600 mg IV q8h) + penicillin G (4 million units IV q4h)
Smallpox (variola virus; Chapter 372)	Synchronous exanthem	Virions stable in environment; population immunologically naïve	Supportive care; cidofovir and ST-246 are promising investigational drugs
Plague (*Yersinia pestis*; Chapter 312)	Hemoptysis	Contagious through respiratory droplets; "Black Death" conjures fear	Gentamicin (5 mg/kg IV qd) or ciprofloxacin (400 mg IV q12h) or doxycycline (100 mg IV q12h)
Tularemia (*Francisella tularensis*; Chapter 311)	Plague-like illness	Bacteria stable in environment; very low infectious dose	Same as for plague
Botulism (botulinum toxins; Chapter 296)	Descending, flaccid paralysis	Highly potent toxin; lends itself to food and water use; cases consume vast resources	Supportive care; ventilator support; botulinum antitoxin may halt (but will not reverse) symptom progression
Viral hemorrhagic fevers (Chapter 381; see Table 21-3)	Hemorrhagic diatheses	Fear factor is paramount; few countermeasures exist	Supportive care; ribavirin may be beneficial in select cases (e.g., Lassa fever, New World arenaviruses, Crimean-Congo hemorrhagic fever virus, hemorrhagic fever renal syndrome) when it is given under an experimental protocol: 30 mg/kg IV load, then 16 mg/kg q6h for 4 days, then 8 mg/kg q8h for 6 days

pain, diarrhea, hematochezia, hematemesis, and ascites. Paracentesis may yield hemorrhagic ascites.

Inhalational anthrax is of greatest concern after an aerosolized bioweapons attack. After an incubation period that averages 1 to 6 days but can be as long as 43 days, patients present with fever, profound drenching sweats, nausea, vomiting, diarrhea, shortness of breath, cough, and chest pain. Without prompt recognition and appropriate therapy, individuals can deteriorate rapidly with increasing dyspnea, stridor, cyanosis, and respiratory failure. Engorgement and hemorrhage of mediastinal lymph nodes with accompanying mediastinitis lead to the clinical hallmark of a widened mediastinum on the chest radiograph in about 60% of cases. Patients may also develop large hemorrhagic pleural effusions and infiltrates. Bacteremic dissemination can lead to widely metastatic infection in the gastrointestinal tract and meninges.

DIAGNOSIS

B. anthracis can be identified by Gram stain or culture of tissue or body fluids, including skin biopsy for cutaneous disease, peripheral blood, pleural effusions, and cerebrospinal fluid but not sputum. A chest radiograph may provide initial clues to inhalational disease with manifestations such as hilar or paratracheal fullness and pleural effusions. A chest computed tomography scan can confirm mediastinal adenopathy. Other techniques, such as fluorescent antibody staining or polymerase chain reaction (PCR), may provide more rapid diagnosis.

TREATMENT Rx

Antibiotics licensed for the treatment of inhalational anthrax include penicillin, ciprofloxacin, doxycycline, and levofloxacin, each for a total duration of 60 days (Table 21-2). After initial empirical therapy, antibiotic selection should be guided by sensitivity testing. In the 2001 outbreaks, patients who received more than one drug appeared to have better outcomes, so one of these drugs should be administered in combination with at least one other drug to which the organism is sensitive. Potential additional drugs include rifampin (300 to 600 mg orally once or twice daily), vancomycin (1 g or 15 mg/kg IV every 12 hours), ampicillin (2 g IV every 4 hours), chloramphenicol (500 mg IV or orally, every 6 hours), imipenem (1 g IV every 6 hours), clindamycin (600 mg IV every 8 hours), and clarithromycin (500 mg orally every 12 hours). Actual treatment doses and durations of combination therapy are based on clinical judgment or expert consultations.[2] A new monoclonal antibody, raxibacumab (single dose of 40 mg/kg IV during 2 hours and 15 minutes after premedicating with diphenhydramine 25 to 50 mg IV), is approved for additional therapy of inhalational anthrax along with antibiotics on the basis of animal efficacy data. Anthrax immune globulin remains an investigational product at this time.

PREVENTION

The anthrax vaccine, which is effective at preventing all forms of disease, has been reserved primarily for high-risk ranchers or veterinarians who have regular contact with herbivores, scientific personnel in research laboratories, and military personnel. The vaccine is now given as five doses intramuscularly during 18 months (day 0, followed by 1, 6, 12, and 18 months), with annual boosters if continued risk exists.

After a known exposure, chemoprophylaxis is recommended with ciprofloxacin (500 mg orally twice daily) or doxycycline (100 mg orally twice daily) for 60 days, although shorter durations are likely to be effective, especially if combined with vaccination. If the vaccine is available, three doses may be given concomitantly with antibiotics, but it is not licensed for this purpose and must be administered under an investigational protocol. Raxibacumab (dosed as before) is also approved for prophylaxis if antibiotics are not available.

PROGNOSIS

Factors associated with survival from anthrax include antibiotics or anthrax antiserum given during the prodromal phase, pleural fluid drainage, and a multiple drug regimen. Case-fatality rates in untreated patients approach 100%, although 55% of the victims of inhalation anthrax survived in a 2001 outbreak because of antibiotics and modern intensive care.

SMALLPOX

EPIDEMIOLOGY

Although smallpox was officially eradicated in 1980, concerns exist about undeclared stores outside approved repositories in the United States and Russia. The recent discoveries of unaccounted for vials of variola in the United States provide some credence to this concern. In addition to near-universal susceptibility, the environmental stability of smallpox viral particles makes it a formidable potential weapon.

Smallpox is caused by variola virus, an orthopoxvirus (Chapter 372) that is closely related to cowpox, vaccinia, and monkeypox. Variola generally spreads to household and other close contacts, but it can spread farther distances through aerosolized droplet nuclei as well as by direct contact with secretions of patients or fomites. Health care providers, who can be infected in the nosocomial setting, or unsuspecting individuals who have contact with contaminated objects are also at risk.

PATHOBIOLOGY AND CLINICAL MANIFESTATIONS

Infection initially occurs in the respiratory mucosa, followed by replication in the regional lymph nodes and then by an asymptomatic primary viremia that seeds the reticuloendothelial system. Approximately 1 week after infection (range, ~1 to 2 weeks), a secondary viremia seeds the skin. At this time, the sudden onset of illness includes fever, headache, backache, and vomiting. Within 2 or 3 days of this prodrome, and often as the temperature falls, the characteristic rash begins with small papules in a centrifugal pattern (more on the face and extremities than on the trunk) that progress in synchronous fashion during the next week to vesicles, umbilicated pustules, and finally scabs. Lesions are deep seated and can be intensely painful. Individuals are contagious at the onset of the rash and are considered to be free of contagion once the scabs have separated.

DIAGNOSIS

Chickenpox (varicella; Chapter 375), which can be confused with smallpox, occurs predominantly on the trunk rather than on the extremities (a centripetal pattern), and the lesions occur in successive crops, so macules, papules, pustules, and scabs can be seen simultaneously. In addition, varicella is transmissible before onset of the rash, but contagiousness abates when all the lesions are scabbed. Other diseases in the differential diagnosis of smallpox include monkeypox (Chapter 372), other poxviruses, disseminated vaccinia in a vaccine recipient or contact, disseminated herpes zoster (Chapter 375) or herpes simplex (Chapter 374), impetigo (Chapter 441), drug eruptions (Chapter 440), contact dermatitis (Chapter 438), erythema multiforme (Chapter 439), and rickettsialpox (Chapter 327).

Clinical recognition of the characteristic rash (Fig. 21-1) should raise suspicion of smallpox. Diagnosis would likely come from PCR or viral culture of skin or blood samples or from acute and convalescent serologies.

TREATMENT Rx

The primary therapy for smallpox remains supportive care. Potential therapies include cidofovir (5 mg/kg IV; duration is determined on the basis of clinical response and potential side effects), a product licensed for treatment of cytomegalovirus retinitis in HIV-infected patients, and the investigational drug ST-246, which has been added to the strategic national stockpile for use in case of a smallpox outbreak.

PREVENTION

Vaccination uses vaccinia, an orthopoxvirus related to variola. In the event of an outbreak, postexposure vaccination within 4 days can prevent or ameliorate disease.[3] The U.S. government has stockpiled enough doses for the entire U.S. population of a newer, cell-cultured product for use in a national emergency. The surveillance and containment or ring vaccination method combines active case finding with vaccination of potential contacts within a certain radius around the cases. Health care providers would need to be vaccinated, and airborne and contact precautions (HEPA filter masks, negative-pressure rooms, gowns, gloves, eye protection) would be recommended in the hospital environment. Although there was an attempt to encourage health care providers to be vaccinated in the aftermath of the 2001 anthrax attacks, this effort was discontinued because of concerns about vaccine side effects, such as myocarditis, and skepticism about the true risk of an outbreak. Because the vaccine is a live agent, it is contraindicated in individuals with eczema or significant exfoliative skin conditions or immune compromise in the pre-exposure setting. Even in normal hosts, it can be associated with inoculation of other locations on the body, spread to close contacts, disseminated disease, postvaccine encephalitis, progressive vaccinia in individuals with defective cell-mediated immunity, eczema vaccinatum in people with prior eczema, and pericarditis or myocarditis. In the postexposure setting,

FIGURE 21-1. Smallpox. ***A,*** Demonstrates centrifugal nature of the rash. ***B,*** Demonstrates coalescences of some pustules. ***C,*** Demonstrates umbilicated pustules. (From Fenner F, Henderson DA, Arita A, et al. Smallpox and its eradication. Geneva: World Health Organization; 1988.)

risk benefits would have to be weighed regarding which individuals at risk for complications might receive vaccine and whether vaccinia immune globulin might be administered concomitantly. First-line therapy for significant vaccine reactions is vaccinia immune globulin.

PROGNOSIS

The case-fatality rate for the typical form of smallpox, known as variola major, is approximately 30%, but wide variations exist among races. In the minority of individuals who develop hemorrhagic smallpox or flat-type smallpox, the case-fatality rate approaches 100%. A different viral strain, variola minor, has case-fatality rates of only about 1%. Survivors of smallpox are often left with lifelong scarring from the lesions. Blindness and bone deformities, especially in children, are also known complications.

PLAGUE

EPIDEMIOLOGY

Plague was responsible for millions of deaths during three pandemics. Plague was used as a weapon by the Japanese before World War II when they released infected fleas in Chinese cities, and it was included in the former Soviet Union's biologic weapon arsenal. Plague is transmissible through the respiratory route, so an aerosol release could have devastating effects.

Plague is caused by the Gram-negative coccobacillus *Yersinia pestis* (Chapter 312). On light microscopy, the organism can have a bipolar appearance, making it look like a safety pin. In general, humans are infected during close proximity with rodents in areas where plague is enzootic or when their pets serve as vehicles for bringing infected fleas or the disease into their household. The "Black Death" of the 14th and 15th centuries owed much of its persistence to the ubiquitous presence of rats in homes and a lack of appreciation for their role in disease transmission.

Each year in the United States, several human cases are reported, usually in the Southwest. Most of these cases are bubonic, although occasional pneumonic plague is linked to infections in domestic cats.

PATHOBIOLOGY AND CLINICAL MANIFESTATIONS

Plague is manifested in three ways. Bubonic plague, which is the most common form, occurs after the bite of an infected flea. The organism spreads through the local lymphatics to the regional lymph nodes. As replication occurs, the lymph node or group of lymph nodes becomes swollen and extremely tender. As most flea bites occur on the lower extremities, the inguinal and femoral lymph nodes are most often affected. Untreated bubonic plague can progress to septicemic plague after organisms gain entry to the blood stream. In addition, patients can develop necrosis of cooler areas of the body, such as the tip of the nose, ears, or digits, as a result of a temperature-dependent coagulase produced by the organism. Septicemic plague may also occur in the absence of an antecedent bubo. Meningitis may occur from seeding through the blood stream. In pneumonic plague, the lungs are seeded secondarily by bacteremia from septicemic plague or primarily when a person inhales infected droplets. Although naturally occurring pneumonic plague is rare, this form of disease is the major concern after intentional aerosol release. In patients with pneumonic plague, viable organisms are found in the sputum, and the disease can then be spread to others. One of the hallmarks of the disease is the potential for purulent sputum to become hemorrhagic.

DIAGNOSIS

Plague bacilli are readily identified with Gram, Wright-Giemsa, or Wayson stains along with culture of the sputum or other infected body fluid, such as blood, fluid from a bubo, or cerebrospinal fluid. Other diagnostic methods include PCR for the F1 antigen, direct fluorescent antibody staining of body fluids, and serology by enzyme-linked immunosorbent assay or passive hemagglutination. However, serology is primarily useful in retrospect, because patients need to be treated empirically before a serologic response occurs.

TREATMENT

Rx

The historic drug of choice has been streptomycin (1 g IM twice daily for 7 to 10 days or for 3 days after the fever remits), but suitable alternatives include gentamicin (5 mg/kg IM or IV daily or a 2 mg/kg load followed by 1.7 mg IM or IV three times daily), doxycycline (200 mg IV load, then 100 mg IV every 12 hours), ciprofloxacin (400 mg IV every 12 hours), and levofloxacin (500 to 750 mg IV once daily) (Table 21-2). The drug of choice for plague meningitis is chloramphenicol (25 to 30 mg/kg IV load, followed by 50 to 60 mg/kg/day every 6 hours; on favorable clinical response, the dose can be reduced to 25 to 30 mg/kg/day every 6 hours).[4]

PREVENTION

Use of standard precautions is appropriate for bubonic plague. Droplet precautions should be applied for patients with pneumonic plague; this generally includes a private room where caregivers wear masks, gowns, gloves, and eye protection within 3 to 6 feet of the patients to minimize spread. These precautions should be continued until the patient demonstrates improvement and has been receiving effective antibiotics for 72 hours. Oral ciprofloxacin, levofloxacin, or doxycycline is recommended for postexposure prophylaxis of household contacts or individuals suspected of exposure in either the endemic or bioterrorism setting. Prophylaxis should continue for 7 days beyond the period of exposure.

No licensed vaccine for plague currently exists in the United States and a previously-licensed whole cell killed vaccine is no longer available. A new

vaccine that uses the F1 and V antigens, which has demonstrated protection in animals against aerosol challenge, is being developed by the Department of Defense and is currently undergoing phase II testing.

PROGNOSIS

Case-fatality rates are 50% or more for untreated bubonic plague and nearly 100% for untreated septicemic and pneumonic plague. These fatality rates can be significantly reduced with prompt recognition and appropriate therapy.

TULAREMIA

Tularemia (Chapter 311) is caused by infection with the Gram-negative, aerobic nonmotile coccobacillary organism *Francisella tularensis*.[5] A zoonotic disease of rabbits, ground squirrels, and other small mammals, tularemia can be acquired by humans by skin or mucous membrane contact with body fluids or tissues of infected animals or from being bitten by infected deerflies, mosquitoes, or ticks. Disease can rarely occur by inhalation of contaminated dusts or ingestion of contaminated food or water. Relatively uncommon in the United States, fewer than 150 cases of naturally occurring human tularemia are typically reported each year. However, the environmental stability of *F. tularensis* as well as its very low infectious dose (as few as 10 organisms) makes it a potential weaponization threat.

CLINICAL MANIFESTATIONS AND DIAGNOSIS

Clinical manifestations of tularemia depend on the route of exposure. Although six different forms (glandular, oculoglandular, ulceroglandular, pharyngeal, pneumonic, and typhoidal) have been described, tularemia is perhaps more simplistically compared with plague, with glandular forms analogous to bubonic plague as well as pneumonic and typhoidal forms that present a clinical picture similar to what is seen in pneumonic and septicemic plague. A preponderance of these latter forms would be expected after an intentional release by aerosol. After an incubation period of 2 to 10 days, symptoms begin with fever and proceed to include severe exhaustion, substernal chest pain, nonproductive cough, and weight loss.

Diagnosis, which requires isolation of the organism in blood, sputum, skin, or mucus membrane lesions, may be difficult because of unusual growth requirements and overgrowth of commensal organisms. Therefore, serology is the mainstay of diagnosis, often in retrospect. Because of the risk of spread to microbiology laboratory personnel, it is important to notify the laboratory if infection with this organism is suspected.

TREATMENT AND PROGNOSIS

Rx

Treatment of tularemia is similar to that of plague, with aminoglycosides for 10 to 14 days; streptomycin and gentamicin are considered the drugs of choice, although ciprofloxacin is a newer potential alternative (Table 21-2). Doxycycline/tetracycline and chloramphenicol are second-line choices because their use has been associated with relapses, and the recommended duration of therapy is 14 to 21 days.

Person-to-person spread is unusual, and standard precautions are adequate in caring for ill individuals. For known exposures, prophylaxis with tetracycline (500 mg orally four times a day for 2 weeks) is effective if it is begun within 24 hours of exposure; consensus recommendations in a bioterrorism setting are doxycycline 100 mg or ciprofloxacin 500 mg orally twice a day as postexposure prophylaxis.[6] A live attenuated vaccine has proven efficacy in preventing disease due to laboratory exposures and aerosol challenge in human volunteers, but it is not readily available to the public.

The case-fatality rate for untreated pneumonic and typhoidal tularemia is 35%, but this rate can be reduced to less than 5% with appropriate treatment.

BOTULISM

Botulism is caused by exposure to one of eight related neurotoxins (A to H) produced by certain strains of *Clostridium botulinum* (Chapter 296), a ubiquitous anaerobic spore-forming Gram-positive bacillus.[7] Botulinum toxins, which are among the most toxic substances known, can be lethal in doses as low as 0.001 µg/kg. These toxins, which act at presynaptic nerve terminals, block the release of acetylcholine, thereby resulting in a generalized flaccid paralysis with autonomic dysfunction. Although most toxins are unstable in the environment and thus constitute dubious weaponization threats, the potent nature of botulinum toxin, coupled with the ease with which it might be used to contaminate food and water, makes it an agent of concern. Naturally occurring human botulism is limited to types A, B, and E, although other toxin serotypes can produce an identical clinical syndrome. For this reason, a heptavalent antitoxin with activity against all seven serotypes has been licensed recently.

CLINICAL MANIFESTATIONS AND DIAGNOSIS

Botulism typically develops after a latent period ranging from hours to several days. Initial manifestations involve bulbar palsies, ptosis, photophobia, blurred vision, and other signs of cranial nerve dysfunction. Symptoms progress craniocaudally, leading to dysphonia, dysphagia, and, ultimately, a descending symmetrical paralysis. In fatal cases, death typically results from respiratory muscle failure.

Although botulism may mimic other neurologic disorders, such as myasthenia gravis and the Guillain-Barré syndrome, the occurrence of an outbreak involving multiple cases of descending, symmetrical, flaccid paralysis should make diagnosis of botulism relatively straightforward.

TREATMENT AND PROGNOSIS

Rx

Supportive care measures plus antitoxin, including meticulous attention to ventilatory support, are the mainstay of botulism management. Patients may require such support for several months, so the management of a large-scale botulism outbreak would be especially problematic in terms of medical resources. Botulism is not contagious, so standard precautions are adequate in managing botulism victims. The first victims of an outbreak may have higher case-fatality rates because of delays in recognition. Those who recover can have long-term sequelae, such as dyspnea on exertion, fatigue, and weakness.

VIRAL HEMORRHAGIC FEVERS

EPIDEMIOLOGY

Viral hemorrhagic fever (Chapter 381) is a term used to describe the clinical syndrome caused by four families of RNA viruses: filoviruses (Ebola and Marburg), arenaviruses ("Old World" Lassa fever and "New World" South American viruses, Machupo, Junin, and others), bunyaviruses (hantaviruses, Crimean Congo hemorrhagic fever, and Rift Valley fever), and flaviviruses (yellow fever and dengue) (Table 21-3).[8] Agents of greatest concern from a bioterrorism perspective include the filoviruses and arenaviruses, which are infectious by the aerosol route and can replicate well in cell culture for large-scale production and whose clinical syndrome of hemorrhage and fever engenders fear. The massive outbreak of Ebola virus disease in West Africa in 2014 demonstrates the devastation that a hemorrhagic fever virus can have on a population, even in the absence of bioterrorism, especially when the medical infrastructure is sub-optimal.[9]

PATHOBIOLOGY AND CLINICAL MANIFESTATIONS

Once virus gains entry through the skin, mucous membranes, or respiratory tract, replication occurs in macrophages and dendritic cells. Organisms are then transported to regional lymph nodes and eventually through the lymphatics and blood stream to target organs, such as the liver and spleen, where local necrosis occurs. The body responds with activation of cytokines and chemokines, and massive depletion of lymphocytes disables the host's adaptive immune response. A sepsis-like picture ensues, with declining mean arterial pressure, increased vascular permeability, and a bleeding diathesis.

Clinical features of the hemorrhagic fevers include the acute onset of malaise, sore throat, fever, skin flushing, conjunctival injection, prostration, myalgias, and nonbloody diarrhea. These viruses have significant differences in the prominence of individual clinical findings. For example, dengue, the filoviruses, and Lassa more commonly cause a maculopapular rash in the first week. The filoviruses and South American viruses more typically cause obtundation and encephalitis. Although all of these produce modest elevations of aminotransferase levels, yellow fever and Rift Valley fever are known for causing significant hepatic dysfunction, thereby resulting in icterus and jaundice. Depending on a number of factors, including virulence, route of exposure, inoculum, and other host factors, illness can progress in the second week to overt signs of bleeding, including petechiae, purpura, ecchymoses, and oozing from venipuncture sites. If massive bleeding occurs, the source is usually the gastrointestinal tract. Severe cases will demonstrate a combination of neurologic and hematologic abnormalities.

TABLE 21-3 COMPARISON OF VIRAL HEMORRHAGIC FEVER AGENTS[4]

FAMILY	VIRUS	ENDEMIC AREA	FATALITY RATE	NOSOCOMIAL TRANSMISSION	COUNTERMEASURES
Filoviruses	Ebola	Africa, Philippines (Reston)	50-90% (Sudan/Zaire)	Yes	Anecdotal success with immune plasma; monoclonal antibodies demonstrate benefit after disease onset
	Marburg	Africa	23-70%	Yes	
Arenaviruses	Lassa	West Africa	1-2%	Yes	Ribavirin effective in a clinical trial with nonrandomized controls
	Junin	Argentine Pampas	30%	Rare	Immune plasma; reports of benefit with ribavirin; Candid 1 vaccine protective; not available in the United States
	Machupo	Bolivia	25-35%	Rare	Immune plasma; reports of benefit with ribavirin
Bunyaviruses	Crimean-Congo hemorrhagic fever	Africa, southeast Europe, Central Asia, India	30%	Yes	Anecdotal success with ribavirin treatment
	Rift Valley fever	Africa	<0.5%	No	Livestock vaccines in Africa; U.S. Department of Defense has two experimental vaccines
	Hantaviruses	Europe, Asia, South America (rare)	5% (Asian hemorrhagic fever with renal syndrome)	No*	Vaccines available in Asia; ribavirin effective in randomized trial but not licensed for that purpose
Flaviviruses	Yellow fever	Africa, South America	3-12%,(20-50% if second phase develops)	No	17D live attenuated vaccine
	Kyasanur Forest	Southern India	3-5%	No	Formalin-inactivated vaccine in India
	Omsk	Siberia	0.2-3%	No	Tick-borne encephalitis vaccines (not in United States) may offer some cross protection

*Exception is Andes, which causes hantavirus pulmonary syndrome (not addressed in this chapter).

DIAGNOSIS

Numerous more common diseases should be considered in the differential diagnosis of a viral hemorrhagic fever, including rickettsial infections (Rocky Mountain spotted fever, ehrlichia, anaplasma, and African tick typhus; Chapter 327), leptospirosis (Chapter 323), meningococcemia (Chapter 298), typhoid (Chapter 308), and falciparum malaria (Chapter 345). However, a viral hemorrhagic fever should be considered in patients who present with a clinically compatible syndrome, especially if a cluster of cases is seen. Laboratory features may include thrombocytopenia, elevated aminotransferase levels, leukopenia, anemia (although an elevated hematocrit may be seen in patients who have significant vascular leakage, as is sometimes seen with dengue and hantaviruses), hematuria, and proteinuria. PCR, viral culture, immunoglobulin M–specific enzyme-linked immunosorbent assay, acute and convalescent serology, or immunohistochemistry on autopsy specimens can establish the diagnosis. Routine clinical specimens and any attempt at viral isolation require a biosafety level 3 or 4 laboratory with expert consultation from the Centers for Disease Control and Prevention or the U.S. Army Medical Research Institute of Infectious Diseases.

TREATMENT

Rx

No licensed therapies exist for the viral hemorrhagic fevers, so supportive care is the primary means of management with close attention to fluid status, avoidance of procedures that cause bleeding and medications that impair platelet function, use of blood products as necessary, use of vasopressors for hypotension, and dialysis for renal failure. Close attention to fluid status has significantly reduced mortality from dengue, and aggressive fluid repletion has been needed to address significant loss of fluid volume due to diarrhea, electrolyte abnormalities, and protein/nutritional depletion in Ebola infections.[10] Oral ribavirin or intravenous ribavirin (see Table 21-2) under an approved experimental protocol can reduce mortality in Lassa hemorrhagic fever, and it also appears to be beneficial against Argentine hemorrhagic fever (Junin virus) and hantaviruses that cause hemorrhagic fever with renal syndrome. It has no apparent efficacy against filoviruses (Ebola or Marburg) or flaviviruses (dengue, yellow fever). Monoclonal antibodies are a potentially promising option for Ebola virus.[11]

PREVENTION

Yellow fever vaccine is the only licensed vaccine against a viral hemorrhagic fever in the United States. Experimental vaccines exist against Junin virus and Rift Valley fever virus, but these vaccines have been used primarily to protect laboratory workers.

Certain viral hemorrhagic fevers (primarily Ebola, Marburg, Lassa, and Crimean-Congo hemorrhagic fever) produce high-level viremia during the period of greatest bleeding risk, thereby making them notorious for causing nosocomial outbreaks. In general, these outbreaks occur in environments, such as sub-Saharan Africa, where basic infection control practices are inadequate because of limited resources (e.g., lack of gowns, gloves, and eye protection as well as reuse of unsterilized needles and syringes). Spread of these viruses in the nosocomial environment can be significantly reduced with standard precautions that limit contact with blood and body fluids. In caring for patients at higher risk of spread (those who are coughing, vomiting, or hemorrhaging), enhanced precautions are recommended, using negative-pressure isolation and N-100 masks along with gowns, gloves, and eye protection. Even with these precautions, the infection of two nurses in Dallas in 2014 from a severely ill patient demonstrates the challenge of doing this right, as there is little room for error.

PROGNOSIS

Hemorrhagic viruses exhibit a wide range of mortality rates, ranging from less than 1% with Rift Valley fever to 80 to 90% with Ebola Zaire (Table 21-3). Despite the notoriety of these viruses for causing hemorrhage, the majority of individuals do not die of blood loss. Rather, death results from a sepsis-like picture, including a loss of vascular hemostasis, disseminated intravascular coagulation, hypotension, renal failure, shock, and death.

RESPONSE TO A BIOTERRORISM ATTACK

Even a relatively small bioterror event can have profound consequences. After the 2001 anthrax mailings, thousands of people were prescribed antibiotic prophylaxis, and government buildings were closed for decontamination. Since that event, significant improvements in future responses to a bioterrorism event include the licensure, manufacture, and storage of enough smallpox vaccine for everyone in the United States, production of anthrax and botulinum antitoxins for the strategic national stockpile, and development of protocols and authority for response. However, no country has yet achieved the ability to detect a pathogen release reliably in real time.[12] The 2014 Ebola outbreak also has identified shortcomings in preparedness in the U.S.

In any future bioterror attack, early warning signs might include clusters of patients with mediastinal adenopathy or widened mediastinum on the chest radiograph, a centrifugal pustular rash (smallpox), pneumonia and hemoptysis (plague), descending flaccid paralysis (botulism), or hemorrhagic manifestations and impaired clotting (viral hemorrhagic fever). Should such a cluster be identified or suspected, physicians should contact the local county or city health department, the state health department, and potentially the Centers for Disease Control and Prevention. Unlike a natural

outbreak, a potential bioterror outbreak also requires a rapid dialogue between public health and law enforcement authorities, in part because patient and environmental samples constitute evidence against a perpetrator and must be handled under chain of custody. Physicians also must be prepared not only to protect themselves and their patients but also to serve as community resources, regardless of whether an outbreak is natural or terrorist in origin.

REVIEW QUESTIONS

1. An air detector in your city has indicated that there has been an aerosol attack with smallpox. This has been verified by the state health department. You are seeing a number of individuals suspected of having been exposed during the attack that occurred 3 days ago. What would be the appropriate management for these individuals?

A. Give vaccinia immune globulin at the earliest opportunity.
B. Vaccinate exposed individuals with the smallpox vaccine (ACAM2000).
C. Vaccinate exposed individuals with the smallpox vaccine, except those with eczema.
D. There is nothing you can offer at this point except reassurance.
E. You can treat them with cidofovir.

Answer: B Studies of historical outbreaks have demonstrated that after individuals are exposed to smallpox, it has been possible to prevent or to ameliorate smallpox disease by vaccination. When it is administered by scarification, replication of the smallpox vaccine (vaccinia virus) can provide immunity faster than the replication of the variola (smallpox) virus. However, the vaccination must occur relatively quickly after exposure, usually within 4 or 5 days, to have maximum likelihood of benefit. Although the vaccine can cause adverse effects in immunocompromised people and individuals with skin disorders, such as eczema, there are no contraindications to vaccination in the event of a true exposure. Cidofovir is potentially nephrotoxic and has been used for treatment but not for prevention. Vaccinia immune globulin is primarily used for treatment of vaccine adverse events, not for smallpox disease. Finally, a newer vaccine, modified vaccinia Ankara, which is believed to have less risk for immunocompromised individuals, is under study as a potential alternative.

2. You become aware of a large outbreak of nontyphoidal *Salmonella* in your community. Which of the following is not true?

A. More cases than would be expected in the community might be a clue of intentional spread.
B. A genetic match between patient isolates, a laboratory at a suspicious local cult, and local salad bars may indicate intentional spread.
C. This outbreak is unlikely to be spread intentionally because *Salmonella* is not considered a high-threat agent.
D. Disease in a specific ethnic group may indicate intentional targeting of the infectious agent.
E. An unusual antibiotic susceptibility pattern of the organism might indicate intentional tampering.

Answer: C Public health authorities have designated certain organisms as most concerning (category A agents) on the basis of characteristics such as the ability to grow in large quantities, stability in aerosol, and ability to infect by the aerosol route. However, we are unable to understand a specific perpetrator's criminal intentions; the perpetrators may not have access to such classic bioweapon agents, and they may instead use an organism that is easier to obtain. This is what occurred in the Dalles, Oregon, outbreak in 1984, when the Rajneesh cult contaminated local salad bars with *Salmonella typhimurium*. These types of outbreaks are difficult to pinpoint as artificially caused, so it is useful to look at historical outbreaks and potential clues as to why this might deviate from what would be expected.

22

CHRONIC POISONING: TRACE METALS AND OTHERS

LOUISE W. KAO AND DANIEL E. RUSYNIAK

About 80% of the elements in the periodic table are metals or metalloids, and various metals are in contact with humans in the home, workplace, and environment. Metals are part of a number of normal physiologic processes, such as iron in hemoglobin, but also can cause a number of toxic adverse effects.[1]

LEAD TOXICITY

EPIDEMIOLOGY

Lead (Pb) is a silver-gray, malleable metal that is resistant to corrosion. It has no known physiologic use, so any lead in the human body should be considered contamination.

The most common sources of lead poisoning are lead-based paints, lead-contaminated dust in older buildings, and lead-contaminated soil. Other sources include plumbing, solder, batteries, bullets, toys, curtain weights, necklace charms, food containers, and cosmetics, including Nigerian eyeliners. Adults in occupations such as battery manufacturing, welding, construction, mining, glass blowing, and shipbuilding have the highest lead exposures. Other less common but important routes of exposure include lead-contaminated moonshine and lead-containing ethnic folk remedies (e.g., greta and azarcon in Mexico).

Children in lower socioeconomic areas have the highest exposures to lead, and the majority of the scientific literature is biased toward pediatric studies. Much of what we have learned, however, is applicable to adults.

PATHOBIOLOGY

Lead's most devastating effects are on the central nervous system (CNS) of children. By disrupting the intracellular junction of capillary endothelium, lead impairs the blood-brain barrier, which further increases CNS absorption. Lead also increases capillary leak, which in severe cases can result in cerebral edema.

Lead inhibits several enzymes involved in heme synthesis: aminolevulinic acid synthetase, δ-aminolevulinic acid dehydratase, coproporphyrinogen decarboxylase, and ferrochelatase. Lead also inhibits the enzyme erythrocyte pyrimidine-5-nucleotidase, which impairs RNA degradation and contributes to red cell hemolysis. Collectively, the inhibition of these enzymes results in decreased concentrations of hemoglobin and a shorter life span of red blood cells.

By depositing lead-protein complexes in renal proximal tubular cells, lead interferes with normal mitochondrial function, thereby resulting in decreased reabsorption of glucose, amino acid, and phosphate. Chronically exposed persons can develop renal failure from tubular atrophy, interstitial fibrosis, and glomerular sclerosis.

Although lead has not been associated with specific bone-related disorders, the skeletal system serves as the main reservoir for lead; with chronic exposure, lead stores in bone can have a half-life of 5 to 19 years. As a result, soft tissues may be subjected to increased lead exposure during times of accelerated bone turnover, such as during childhood growth, after a long bone fracture, or during pregnancy.

CLINICAL MANIFESTATIONS

Lead poisoning can be subtle and difficult to diagnose because many of its historical clinical associations (e.g., neuropathy, gout, abdominal colic) are rarely seen today. In children, the most concerning long-term complications of environmental lead exposure are developmental cognitive deficits, especially when lead concentrations in young children exceed 100 µg/dL. Subacute neurologic problems include ataxia, lethargy, seizures, and coma. Adults can also experience severe neurologic symptoms (e.g., seizures and cerebral edema) with plumbism, but typically only when whole blood lead levels are higher than 150 µg/dL. More commonly, the neurologic problems caused by lead in adults are manifested as memory problems, insomnia, depression, and personality changes.

Other clinical effects of lead poisoning, in both children and adults, include a normocytic or microcytic anemia, abdominal pain, hepatotoxicity, and pancreatitis. The classic finding of peripheral neuropathy with footdrop and wristdrop is well described in adults but only occasionally seen in children. Nephrotoxicity most commonly is manifested as Fanconi syndrome (Chapter 128) with aminoaciduria, glycosuria, and phosphaturia. A consequence of this toxicity is impaired uric acid clearance and gout.[2] High lead levels also probably increase the risk of hypertension.

DIAGNOSIS

Diagnosis of lead intoxication involves a high level of suspicion. The best initial test is a whole blood lead level collected in a certified lead-free tube (Table 22-1). The blood lead level can be falsely elevated in individuals who have received chelation therapy, which mobilizes tissue lead stores, in the prior 7 days.

Radiographic imaging can support the diagnosis of lead poisoning and sometimes detect a lead-containing object or a retained bullet. Bone x-ray fluorescence technology can estimate bone lead levels, which can reflect chronic lead exposure, but this test is mostly a research tool and is not commonly available in clinical practice.

TREATMENT

Rx

The first step in management of patients with elevated lead levels is prompt removal of the source, although the effectiveness of environmental cleanup and educational initiatives is disappointing.[3] If lead comes from a work-related source, the Occupational Safety and Health Administration should be contacted. Chelation increases excretion of lead in a 24-hour urine sample and thereby decreases blood concentrations, but studies to date with the chelating agent succimer (2,3-dimercaptosuccinic acid, DMSA) in children have not shown improved neuropsychological function[3,4] despite success in reducing blood lead levels. The current recommendation is that asymptomatic adults with blood lead levels of less than 70 µg/dL do not require chelation, patients with mild symptoms or blood lead levels between 70 and 100 µg/dL should receive only oral chelation, and patients with lead-induced encephalopathy or blood lead levels above 100 µg/dL should be considered for parenteral chelation. Although DMSA is approved by the Food and Drug Administration only for children, it also is commonly used in adults (Table 22-2).

Whole bowel irrigation with a polyethylene glycol–electrolyte solution should be considered if a patient has retained a gastrointestinal lead object. Patients who have lead-containing bullet fragments lodged in soft tissues or joint spaces may need to have them surgically removed.

PROGNOSIS

Despite controversy about long-term recovery from lead-associated cognitive deficits in children, adults with neurologic symptoms improve with removal of the exposure. The hematologic and nephrotoxic effects of lead also are reversible.

MERCURY TOXICITY

EPIDEMIOLOGY

Mercury (Hg) is a naturally occurring metal with three distinct forms. Although all forms are neurotoxic, elemental mercury (Hg^0) also causes pulmonary toxicity, inorganic mercury (Hg^+ or Hg^{++}) causes gastrointestinal and

renal toxicity, and organic mercury (ethyl, methyl, alkyl, or phenyl) is a teratogen.

Elemental mercury is found in dental amalgams, thermometers, fluorescent lamps, batteries, and some paints. Occupational exposures may occur in dentists and dental hygienists, painters, gold extractors, bronzers, electroplaters, metallurgists, paper pulp manufacturers, miners, ceramic workers, and other workers who use mercury in processing. Mercury thermometers are becoming increasingly rare, and many countries have banned them because of potential mercury toxicity. Toxicity from elemental mercury is caused primarily from breathing its volatilized vapor.

Inorganic mercury has been used historically as a medicinal, cosmetic, and topical antiseptic in the forms of HgCl (calomel) and $HgCl_2$ (mercuric chloride). It is also used in the tanning industry, in taxidermy, in manufacturing of fireworks, and in dye manufacturing. Inorganic mercury may also be found in patent medicines, folk remedies (such as empacho among Mexican Americans), skin lightening creams, and Asian herbal remedies. Toxicity may occur from ingestion, inhalation, or dermal absorption.

Organic mercury compounds can be classified as short-chain alkyl (such as methylmercury), long-chain alkyl, and aryl compounds. The aryl compounds, such as thimerosal, behave like inorganic mercurial compounds. Methyl mercury has caused several large-scale human poisoning epidemics.

Soil and marine organisms methylate inorganic mercury from the air and industrial waste. Through a process known as bioamplification, methyl mercury concentrates in the tissues of marine life, reaching highest concentrations in large predatory fish such as tuna and swordfish. Fish consumption is now the largest route of organic mercury exposure in the general population. Organic mercury is also used as a fungicide, pesticide, wood preservative, and medicinal antiseptic or preservative (Mercurochrome and thimerosal). Toxicity is typically by ingestion.

TABLE 22-1 DIAGNOSTIC TESTING FOR METALS: REFERENCE RANGES

METAL	SERUM LEVEL	WHOLE BLOOD LEVEL	SPOT URINE	24-HOUR URINE
Lead		<10 µg/dL		
Mercury		<10 µg/L	<20 µg/L	<5 µg/g creatinine
Arsenic		<5 µg/L		<50 µg/L or <100 µg/g creatinine
Cadmium		<5 µg/L		<3 µg/g creatinine
Aluminum	<2 µg/L	<12 µg/L		4-12 µg/g creatinine
Bismuth	<1 µg/dL	<5 µg/dL	<20 µg/L	
Cobalt	0.1-1.2 µg/L		0.1-2.2 µg/L	
Manganese	0.9-2.9 µg/L	4-15 µg/L		<10 µg/L
Silver	<1 µg/L			<2 µg/L
Thallium		<2 µg/L		<5 µg/L
Zinc	109-130 µg/dL	600-1000 µg/dL		<500 µg/day

Modified from Nelson L, Goldfrank LR. Goldfrank's Toxicologic Emergencies. 9th ed. New York: McGraw-Hill Medical; 2011.

PATHOBIOLOGY

The pathophysiology of mercury poisoning is related to its disruption of cell physiology by binding to sulfhydryl, phosphoryl, carboxyl, and amide groups, thereby causing widespread dysfunction of normal cellular mechanisms. Each type of mercury causes differential effects depending on its route of exposure, solubility, and lipophilicity.

Elemental mercury is poorly absorbed by ingestion. If gastrointestinal motility or mucosal integrity is compromised, however, elemental mercury

TABLE 22-2 CHELATORS FOR ADULT HEAVY METAL POISONING

SYMPTOMS	CHELATOR	RECOMMENDED DOSE†	ADVERSE EFFECTS
LEAD			
Asymptomatic, BLL* < 70	None		
Mild-moderate, BLL 70-00	DMSA	10 mg/kg tid PO × 5 days, then bid for 14 days	Nausea, vomiting, diarrhea; mild elevations in aminotransferase levels
Encephalopathy, BLL > 100	BAL +	4 mg/kg deep IM q 4 h × 5days	Local injection site (pain, redness, sterile abscess); nausea, vomiting, diarrhea; anxiety, hypertension, tachycardia, fever; contraindicated in peanut allergy
	$CaNa_2EDTA$‡	1500 mg/m^2/day (approximately 50-75 mg/kg/day) either continuous infusion or in 2-4 divided IV doses for 5 days	Renal toxicity (from metal chelate), constitutional symptoms, transient hypotension
MERCURY			
Acute (elemental or inorganic) with moderate/severe symptoms	BAL	5 mg/kg deep IM then 2.5 mg/kg every 12-24 hours for 10 days or until symptoms improve and patient is able to take PO	Local injection site (pain, redness, sterile abscess); nausea, vomiting, diarrhea; anxiety, hypertension, tachycardia, fever; contraindicated in peanut allergy
Chronic (elemental or inorganic) or organic with symptoms	DMSA	10 mg/kg tid PO × 5 days, then bid for 14 days	Nausea, vomiting, diarrhea, mild elevations in aminotransferase levels
ARSENIC			
Acute exposure with moderate to severe symptoms	BAL	3 mg/kg deep IM q 4 h × 2 days, then bid for 7 to 10 days	Local injection site (pain, redness, sterile abscess); nausea, vomiting, diarrhea; anxiety, hypertension, tachycardia, fever; contraindicated in peanut allergy
Chronic exposure with moderate symptoms§	DMSA	10 mg/kg tid PO × 5 days, then bid for 14 days	Nausea, vomiting, diarrhea, mild elevations in aminotransferase levels
ALUMINUM			
Acute or chronic exposure in dialysis patient with encephalopathy	Deferoxamine	See *http://www2.kidney.org/professionals/kdoqi/guidelines_bone/Guide12.htm*	Hypotension, increased risk of sepsis, acute lung injury
THALLIUM			
Acute thallium poisoning with moderate to severe symptoms	Prussian Blue	3 g tid PO until the urinary thallium excretion is less than 0.5 mg/day	Constipation, blue stool

*Adult recommendations.
†Chelation doses in general are not well studied or validated, with the exception of lead in children. Optimal dosing is not well established, particularly for BAL. Doses listed are author's suggestions.
‡Start 4 hours after first dose of BAL is administered.
§Benefit in this setting is not established.
BAL = British anti-Lewisite, dimercaprol; BLL = blood lead level; DMSA = 2,3-dimercaptosuccinic acid; succimer; EDTA = ethylenediaminetetraacetic acid.

may ionize into more readily absorbed forms. Elemental mercury toxicity occurs primarily by inhalation of the vapor into the alveoli, where it is well absorbed in the pulmonary circulation and readily crosses the blood-brain barrier. In the brain, it interferes with multiple cellular processes, including protein and nucleic acid synthesis. Mercury also inhibits catechol-*O*-methyltransferase, thereby elevating circulating catecholamine levels.

Inorganic mercury is absorbed after ingestion, initially binds the gastrointestinal mucosa, and accumulates in the kidneys, where it exerts direct oxidative damage. Although it does not readily cross the blood-brain barrier, CNS toxicity can be seen with chronic exposures because of the prolonged elimination rate. Mercuric ions do not appear to cross the placental barrier.

Organic mercury compounds are readily absorbed after ingestion and inhalation and are moderately absorbed after dermal exposure, particularly if skin is not intact. Owing to its high lipid solubility, organic mercury crosses the blood-brain barrier and concentrates in the CNS. It can also cross the placental barrier and concentrate in the fetus. Organic mercury concentrates in red blood cells, distributes throughout the body, and is primarily eliminated in the feces. Some forms of organic mercury are metabolized in the body to inorganic mercury compounds. Toxicity results from its inhibition of enzyme systems and interference with cellular maturity, microtubule function, and neurotransmitter synthesis and uptake.

CLINICAL MANIFESTATIONS

The manifestations of elemental mercury toxicity vary depending on the dose and chronicity of the exposure.[5] Inhalation of high concentrations of mercury vapor, as may occur in an industrial setting, may result in cough, chills, fever, and shortness of breath. Nausea, vomiting, and weakness may result. This syndrome may progress to a severe acute lung injury and respiratory as well as renal failure. Chronic exposure to lower concentrations of mercury vapor produces a classic triad of tremor, gingivostomatitis, and neuropsychiatric disturbances. The mercurial tremor may be both static and intentional. Sudden episodic bursts of tremor, also called tetanus mercurialis, have been described. Neuropsychiatric manifestations of mercury poisoning, also known as erethism, include fatigue, insomnia, memory dysfunction, social withdrawal, shyness, and depression.

Inorganic mercury poisoning can occur after dermal or mucosal absorption of mercury-containing cosmetics and teething powders as well as after accidental or intentional ingestion of mercuric chloride antiseptics. After acute ingestion, a hemorrhagic gastroenteritis is typically followed by renal failure from acute tubular necrosis. Chronic exposure is associated with erethism, renal dysfunction, and neurologic manifestations such as sensorimotor neuropathy, constriction of visual fields, tremor, and delirium. Acrodynia, or pink disease, has been described after elemental or inorganic mercury exposure, most notably in children after exposure to mercurial teething powder and diaper ointment. This syndrome is manifested as an erythematous, hyperkeratotic, often desquamating rash on the palms, soles, and face in conjunction with a papular rash. Acrodynia is also associated with an idiosyncratic hypersensitivity to mercury ions and mercury poisoning, which itself can increase circulating catecholamines and mimic pheochromocytoma (Chapter 228). Common findings include tremor, diaphoresis, tachycardia, and hypertension.

Human toxicity from organic mercury was first recognized when the dumping of mercury-containing waste into Minamata Bay in Japan led to a large-scale poisoning of the population, whose primary dietary staple was fish from the bay. In what is now called Minamata disease, patients presented with paresthesia, ataxia, dysarthria, tremor, and constriction of visual fields or "tunnel vision." These symptoms can be progressive and sometimes fatal. Children born to exposed mothers (congenital Minamata disease) suffer mental retardation, limb deformities, chorea, seizures, and microcephaly.

With organic mercury toxicity, symptoms are typically delayed for weeks to months. Other symptoms that follow organic mercury poisoning include mucous membrane irritation after ingestion and dermatitis after cutaneous exposure. However, no cardiovascular toxicities have been reported with up to moderate elevation in blood mercury levels.[6]

DIAGNOSIS

The diagnosis of mercury poisoning should be considered on recognition of the characteristic signs and symptoms coupled with a known or suspected exposure. Whole blood and urine mercury levels can confirm the exposure, but the correlation between levels and symptoms is inconsistent. In the setting of elemental mercury ingestion or injection, radiographs may also be useful. In a nonoccupationally exposed patient, whole blood mercury concentration should not exceed 10 µg/L, and a 24-hour urine mercury concentration should not exceed 20 µg/L (Table 22-1); urine must be collected in an acid-washed container. In general, urine concentrations are more reliable for monitoring of exposure and the response to therapy, but whole blood concentration is the preferred monitoring test for methyl mercury poisoning. The ratio of red blood cell to plasma mercury can differentiate organic mercury toxicity from inorganic mercury toxicity because organic mercury concentrates significantly in red blood cells. Hair analysis is unreliable because of the potential for external contamination. The practice of obtaining urine mercury levels after a chelation challenge is not recommended because levels obtained in this way are difficult to interpret.

TREATMENT

Rx

Treatment is primarily symptomatic and supportive, with removal from the source of exposure. In cases of acute exposure, decontamination may be required. In cases of occupational or environmental exposure, environmental decontamination and surveillance by local or federal agencies may be necessary. After inhalation of elemental mercury vapor, support of respiratory function is crucial. After ingestion of inorganic mercury salts, fluid resuscitation, usually with normal saline, is needed to correct intravascular depletion, and renal replacement therapy may be required in cases of oliguric renal failure. Mercury compounds are poorly cleared by extracorporeal elimination measures, such as hemodialysis or peritoneal dialysis.

If dietary fish is the likely cause of an elevated mercury level, affected individuals should avoid eating any fish or shellfish for 1 month, after which blood or urine mercury levels should be reanalyzed. If mercury levels have declined into the normal range, as is usually the case, low-mercury fish (shrimp, canned light tuna, salmon, pollock, catfish) can be reintroduced into the diet at a frequency of no more than two meals per week.

Chelation therapy will increase urinary elimination of mercury (Table 22-2), and limited clinical data support its use early after acute poisonings. Oral DMSA, which is the chelator of choice, is generally well tolerated. If oral administration is not possible, dimercaprol (British anti-Lewisite, BAL) can be used except after methyl mercury exposure, in which it is contraindicated because it may shift mercury into the brain.

PROGNOSIS

The neurotoxicity that follows significant poisoning from all types of mercury may be irreversible, particularly in the setting of organic mercury poisoning, in which the diagnosis is often delayed. Nevertheless, 33 of 40 symptomatic children affected in the contaminated grain outbreak of 1971 in Iraq improved during a 2-year observation period. Acute renal failure after elemental or inorganic mercury poisoning can sometimes resolve. Patients with acrodynia have been reported to recover completely after chelation therapy and removal of the exposure.

ARSENIC TOXICITY

EPIDEMIOLOGY

Arsenic (As), which is found in soil, minerals, rocks, and metal ores, is present in all living organisms. It exists in several forms: elemental, inorganic (As^{3+} trivalent arsenite and As^{5+} pentavalent arsenate), gaseous (arsine, AsH^3), and organic. Elemental and organic arsenic have low toxicity, whereas gaseous arsine and inorganic arsenic are highly toxic. Arsenic's medicinal properties were recognized as early as 400 BC, and it has been used throughout history as a medicinal as well as a component of pigments, cosmetics, and famously as a poison.

Human exposure to arsenic may occur through contaminated air, groundwater, soil, and food, particularly seafood, rice, and produce. Marine organisms, especially shellfish, contain organic arsenicals arsenobetaine and arsenocholine, which are commonly reported in laboratory assays as elevated arsenic level but exert no known toxic effects.

In Bangladesh, ongoing epidemic arsenic poisoning from contaminated groundwater has affected millions of persons. Taiwan, Chile, the Cordoba province in Argentina, West Bengal, and other regions in the Ganga plain also have elevated levels of naturally occurring arsenic and cases of arsenic poisoning.

Occupational exposure to arsenic occurs in the microelectronics industry, where arsenide crystals are used to etch circuits on microchips. Arsine gas is liberated when inorganic arsenic contacts acid, as may occur in occupations such as metal smelting, galvanizing, and semiconductor manufacturing. Arsenic compounds are also used in the production of paint, fungicide,

insecticide, pesticide, herbicide, wood preservatives, ceramics, and glass, and employees in these industries may also be potentially exposed.

Arsenic compounds may still be found in folk remedies and patent medicines. Modern medicinal uses of arsenic include arsenic trioxide (Trisenox) for the treatment of acute promyelocytic leukemia (Chapter 183) and melarsoprol, an organic arsenical, for the treatment of African trypanosomiasis (Chapter 346).

PATHOBIOLOGY

The toxicologically significant arsenic compounds are inorganic (trivalent and pentavalent). Arsine gas, which is also toxic, causes acute hemolysis. After absorption, inorganic arsenic binds to hemoglobin and is distributed to liver, kidney, heart, and lungs. In the liver, arsenic is methylated to form monomethylarsenoic and dimethylarsinic acid, both of which are less toxic. Arsenic concentrates in keratin-rich tissues, such as hair, skin, and nails. Much of an ingested dose of arsenic is eliminated in the urine. The mechanism of toxicity is by binding sulfhydryl groups of critical enzymes, including those of the Krebs cycle, thereby resulting in impaired gluconeogenesis, impaired oxidative phosphorylation, and ultimately depletion of cellular energy stores. Pentavalent arsenate may substitute for phosphate in biochemical reactions and disrupt normal oxidative phosphorylation. Arsenic also affects cardiac conduction by blocking cardiac potassium channels. Arsenic can alter gene expression through induction, downregulation, and upregulation of various genes involved in apoptosis, cell signaling, and growth factor response.

Arsine is a colorless, nonirritating gas. After inhalation, it is absorbed rapidly and binds to erythrocytes, where it exerts oxidative stress and causes severe Coombs-negative intravascular hemolysis. Renal failure is due to hemoglobin pigment deposition as well as to the direct toxic effects of arsine on renal tubular cells.

CLINICAL MANIFESTATIONS

The initial clinical features after ingestion of inorganic arsenic are nausea, vomiting, bloody diarrhea, and abdominal pain. Within several days, hematologic findings such as pancytopenia can be seen. QT prolongation, which can develop acutely or chronically, can lead to dysrhythmias such as torsades de pointes. After gastrointestinal symptoms improve, distal symmetrical peripheral neuropathy develops, potentially accompanied by weakness or encephalopathy.

Chronic exposures affect the bone marrow, skin, and peripheral nervous system.[7] Dermatologic effects include patchy or diffuse alopecia, hyperpigmentation, and melanosis as well as hyperkeratosis on the palms and soles. The pigmentation of chronic poisoning commonly appears in a finely freckled, "raindrop" pattern of symmetrical pigmentation or depigmentation that is particularly pronounced on the trunk and extremities. Nails may exhibit transverse white bands, which are known as Mees lines (Chapter 442) and reflect growth interruption during poisoning. Anemia, pancytopenia, neutropenia, thrombocytopenia, and eosinophilia can be seen. Neuropathy, which is a hallmark of arsenic poisoning, is described as a diffuse, symmetrical, ascending, painful sensorimotor neuropathy, most prominent in a stocking-glove distribution. In severe poisoning, ascending weakness and paralysis may result in respiratory failure that mimics the Guillain-Barré syndrome (Chapter 420). Arsenic exposure also causes a dose-dependent decline in lung function. Peripheral vascular disease, including peripheral vascular gangrene (black foot disease), can develop in chronically exposed patients. Even low to moderate chronic arsenic exposure increases the long-term risk of cardiovascular disease by about 30%.[8] Arsenic is a human carcinogen, and exposed populations have an increased risk of developing malignant neoplasms in the lung, skin, and bladder.

Arsine gas produces a clinical triad of abdominal pain, hemolysis, and hematuria, typically occurring hours after exposure. Patients may initially have headache, weakness, nausea, and vomiting. Several weeks after an acute exposure, peripheral neuropathy may develop.

DIAGNOSIS

Because arsenic clears from the blood quickly, an arsenic level above 100 µg/24 hours in urine collected in an acid-washed container requires further scrutiny (Table 22-1). Arsenic levels above 50 µg/L in a spot urine test warrant a 24-hour test. Patients who have recently ingested seafood may have urine arsenic levels exceeding 1500 µg/L, exclusively from organic arsenic, so differentiating inorganic from nontoxic organic arsenic is often critical. Total arsenic levels in hair or nails, where arsenic accumulates, are useful indicators of past exposures. Blood arsenic, urine arsenic, and urine arsenic metabolites can be used to confirm recent or ongoing exposure. In the unexposed individual, blood arsenic should be below 1 µg/L; hair and nail levels should be less than 1 ppm.

In patients with chronic arsenic exposure, a complete blood count may show anemia (normocytic, normochromic, or megaloblastic), leukopenia, and thrombocytopenia. A peripheral smear may show basophilic stippling (Fig. 157-14) or karyorrhexis. Renal dysfunction, hepatic enzyme elevation, and hyperbilirubinemia may be seen as well. The electrocardiogram may show QT prolongation and nonspecific ST-T wave changes. Nerve conduction studies typically show evidence of a distal symmetrical sensorimotor axonopathy. Conduction slowing may be seen in severe poisoning.

TREATMENT

Rx

Initial treatment of arsenic toxicity includes supportive care, fluid repletion, decontamination if needed, and removal of the source of exposure. Hemodialysis may be required in patients who have significant renal dysfunction.

In cases of severe acute poisoning from inorganic arsenic, chelation is beneficial if it is instituted early. Dimercaprol (BAL; Table 22-2), which is the traditional chelating agent for arsenic, is effective in decreasing morbidity and mortality if it is administered within minutes to hours of acute exposure. In a small randomized trial, 2,3-dimercapto-1-propanesulfonate, which is not commercially available in the United States, significantly improved clinical symptoms, especially weakness, skin pigmentation, and lung disease, when given as 100 mg orally four times daily every other week for four cycles.[■] The oral analogue of BAL, dimercaptosuccinic acid (DMSA, succimer) is also useful for subacute or chronic arsenic poisoning. In chronic inorganic arsenic intoxication, however, a clear benefit of chelation therapy has not been demonstrated.

Hemolysis caused by arsine gas poisoning should be treated with prompt exchange transfusion. Exchange transfusion can restore functional erythrocytes, remove hemoglobin pigments, remove arsenic itself, and remove toxic products formed in the arsine-hemoglobin reaction.

PROGNOSIS

Outcomes after arsenic poisoning are influenced by the dose, type of arsenic compound, and route and chronicity of exposure. Acute high-dose arsine gas inhalation with severe and rapid systemic toxicity can be fatal. With appropriate treatment, however, recovery has been reported. After acute inorganic arsenic ingestion, rapid diagnosis and treatment, including chelation, can reduce mortality from about 75% to about 45%. After acute or chronic arsenic poisoning, electrocardiographic abnormalities and bone marrow suppression are generally reversible after exposure ceases, but encephalopathy and neuropathy may be permanent. Skin changes, such as hyperpigmentation and hyperkeratoses, can progress to cancer but also can improve if exposure is reduced.

CADMIUM TOXICITY

EPIDEMIOLOGY

Cadmium (Cd) is primarily found in zinc ores as cadmium sulfide. Serious human exposures usually come from industrial use, including the production of nickel-cadmium batteries, electroplating, soldering, and welding. Workplace exposures occur through inhalation of dust containing oxides of cadmium or fumes from welding or smelting of metals containing cadmium. Depending on the particle size, more than 50% of cadmium can be absorbed through the lungs, but little cadmium is absorbed through the gastrointestinal tract. Many plants take up cadmium from the environment, but poor oral bioavailability and relatively low food concentrations make ingestion of food an unlikely source of significant cadmium, except when cadmium-containing industrial waste is dumped in agricultural regions, such as happened when cadmium-containing mining waste in waterways that irrigated rice fields caused a large outbreak of renal disease. Patients with renal disease often developed osteomalacia (Chapter 244), which can lead to painful fractures. Today, the most common source of environmental cadmium exposure is through smoking, because tobacco concentrates cadmium from the soil, and smoking exposes the lungs to these high levels of cadmium. Compared with nonsmokers, an average smoker has about double the concentration of total body cadmium.

PATHOBIOLOGY

Cadmium commonly exists as a divalent ion (Cd^{2+}) in salts such as cadmium sulfide and cadmium oxide. Like other divalent metals, it binds to

and inhibits sulfhydryl-containing proteins and enzymes, thereby resulting in oxidative stress, cellular apoptosis, or necrosis. To survive in an environment where metals are ubiquitous, mammals have developed numerous antioxidant systems for protection. The one best studied in cadmium is the protein metallothionein, which is an intracellular, cysteine-rich protein especially found in the liver and kidney, where it is a potent protective antioxidant that binds to ionized cadmium.

CLINICAL MANIFESTATIONS

The most life-threatening manifestation of cadmium toxicity is acute chemical pneumonitis (Chapters 93 and 94). In persons who are exposed to high concentrations of cadmium fumes (e.g., smelter or welders), cadmium pneumonitis is manifested like metal fume fever with fever, malaise, myalgias, and elevated white blood cell counts that develop within 12 hours of exposure. Unlike metal fume fever, which typically resolves within a few days, cadmium pneumonitis can progress, with symptoms of dyspnea, hemoptysis, pulmonary edema, and respiratory distress as well as diffuse bilateral alveolar infiltrates on the chest radiograph.

The most problematic manifestation of chronic cadmium exposure is renal failure. Like lead, cadmium can damage the proximal tubules of the kidney and result in Fanconi syndrome (Chapter 128). Cadmium, bound to metallothionein, accumulates in the kidney, where its half-life is decades. Once metallothionein binding is saturated, toxicity can develop. Unlike the acute pulmonary manifestations, renal symptoms of cadmium toxicity may have a latency of 10 years of longer. Clinically, the signs of renal disease from cadmium are not different from those of other causes of proximal tubular disease. Patients will often manifest secondary symptoms of renal dysfunction, such as osteoporosis or ureteral stones, from impaired calcium metabolism. Hypertension and anemia from cadmium exposure are also likely secondary to its renal toxicity.

DIAGNOSIS

No laboratory tests can aid in the diagnosis of cadmium pneumonitis, so physicians must rely on their clinical suspicion or on alveolar infiltrates on a chest radiograph in a worker who presents with influenza-like symptoms.

Diagnosis of renal toxicity from chronic cadmium exposure relies predominantly on a 24-hour urine cadmium level standardized to grams of creatinine in a certified laboratory experienced in heavy metal testing (Table 22-1). In nonexposed nonsmokers, cadmium values should average about 0.08 µg per gram of creatinine. Levels of 7 µg cadmium per gram of creatinine and higher require removal from the workplace. For patients with levels above 3 µg cadmium per gram of creatinine, a medical evaluation and renal testing are indicated. Renal dysfunction has been reported in patients with lower levels, and the best test for evaluating renal function is urinary β_2-microglobulin levels, which serve as a useful early marker of toxicity; levels above 300 µg cadmium per gram of creatinine should raise concern for early kidney disease.

TREATMENT

Rx

Because of the similarities between cadmium pneumonitis and metal fume fever, any patient presenting with influenza-like symptoms after working with heated cadmium should be admitted for observation. If the metal a patient was welding or cutting is not known, any clinical or radiographic sings of noncardiogenic pulmonary edema would also warrant hospital admission for supplemental oxygen and pulmonary support.

There are no effective treatments for renal toxicity caused by cadmium. Chelation therapy is not recommended.

PROGNOSIS

Patients with cadmium pneumonitis can survive with aggressive treatment, but severe cases can result in death, and survivors can have persistent restrictive lung disease. Because of its long half-life in the kidney, cadmium-induced renal damage is largely irreversible unless it is detected early when body burden is low (urinary cadmium < 10 µg per gram of creatinine).

SYNDROMES SPECIFIC TO OTHER TOXIC METALS

Aluminum (Dialysis Dementia)

In the 1970s, renal failure patients exposed to aluminum-containing phosphate binders or aluminum-contaminated dialysis fluid developed progressive neurologic impairment and multifocal seizures. Also known as dialysis dementia, this syndrome developed during weeks to years and was often fatal if undetected. Aluminum-containing phosphate binders and dialysis fluids are no longer used in patients with renal failure, and dialysis patients are routinely screened for aluminum toxicosis. However, occasional outbreaks continue to be reported, typically due to contamination of dialysis fluid with aluminum from electric pumps or drums.

Aluminum is found in air, soil, and water and is a component of metal alloys used in the home, such as cookware. Aluminum is also found in some antacids (sucralfate) and as aluminum potassium sulfate (Alum), which is used to treat hemorrhagic cystitis. Additional iatrogenic sources of aluminum include total parenteral nutrition solutions and vaccines. Ingested aluminum is not metabolized by the body and is excreted unchanged by the kidney. In patients with impaired renal function, aluminum is bound to transferrin and concentrates primarily in bone. Smaller amounts, however, are distributed to heart, liver, kidney, and brain. Ingested aluminum is thought to affect several biochemical functions, including neurotransmitter manufacture, uptake, and release. Aluminum also affects erythropoiesis and the normal function of bone, likely partially by interference with parathyroid function.

CLINICAL MANIFESTATIONS AND DIAGNOSIS

Clinical effects in patients with chronic exposures include anemia, osteomalacia, and neurologic effects including memory loss, tremor, dyspraxia, encephalopathy, and seizures. The relationship between aluminum and Alzheimer dementia has been debated, but the complex characteristics of aluminum bioavailability make it difficult to produce conclusive evidence.

Serum and urine aluminum levels can be obtained to estimate exposure. A serum aluminum concentration should not exceed 2 µg/L, and a 24-hour urine concentration is expected to be 4 to 12 µg per gram of creatinine in a patient with typical background aluminum exposure (Table 22-1).

TREATMENT AND PROGNOSIS

Rx

Management of aluminum toxicity centers on removal from the source of exposure. The only chelator with proven benefit is deferoxamine (Table 22-2), which has a high affinity for aluminum and forms a dialyzable aluminum-deferoxamine complex.[9,10] If it is detected early, successful treatment with full recovery of neurologic function has been reported with deferoxamine.

Bismuth (Bismuth Encephalopathy)

Bismuth salts used to treat gastrointestinal disorders include bismuth subgallate, bismuth citrate, bismuth subnitrate, and bismuth subsalicylate (the active ingredient in Pepto-Bismol). Bismuth (Bi) is poorly absorbed from the gastrointestinal tract and is still used today to treat peptic ulcer disease and diarrhea. It also is used as an oral deodorant for patients with colostomies. Idiopathic bismuth toxicity is almost always associated with the chronic ingestion of over-the-counter preparations.

CLINICAL MANIFESTATIONS AND DIAGNOSIS

Bismuth toxicity is manifested primarily as a subacute encephalopathy with ataxia and incoordination followed by progressive memory loss, behavioral changes, insomnia, and muscle cramps. As symptoms progress, a prevalent feature is limb myoclonus when patients are startled or as they fall asleep. As symptoms worsen, myoclonus can progress to involve the whole body, including the tongue, and can occur without stimulus. Seizures can also develop.

The diagnosis of bismuth encephalopathy can be difficult. Blood and urine levels can indicate exposure to bismuth (Table 22-1) but do not correlate with symptoms. Furthermore, electroencephalographic findings, laboratory tests, and imaging studies are not specific. Because of its similarity in onset and symptoms, bismuth encephalopathy is often misdiagnosed as Creutzfeldt-Jakob disease (Chapter 415) or other progressive encephalopathies. Therefore, any patient in whom these diagnoses are being entertained should be screened for the use of bismuth products. As bismuth causes black stools, the finding of heme-negative black stool in a patient with a rapidly progressing encephalopathy should also warrant an investigation for bismuth toxicity.

Cobalt (Thyroid and Cardiac Toxicity)

Cobalt (Co) is an essential trace element that serves as the catalytic center of vitamin B_{12}. Toxicity is most commonly associated with chronic ingestion of

TREATMENT AND PROGNOSIS

Rx

The treatment of bismuth encephalopathy is to stop the use of the offending agent. Although there have been case reports purporting the benefits of metal chelators (e.g., DMSA, BAL, and 2,3-dimercapto-1-propansulfonic acid; Table 22-2) the rarity of the disorder makes a clinical trial impossible. Ethylenediaminetetraacetic acid (EDTA) may increase brain bismuth concentrations, and it should not be used. Although deaths have occurred from bismuth encephalopathy, full recovery is possible if the offending drug is stopped and the patient receives modern supportive care.

cobalt salts and more recently from cobalt-containing metal prostheses. One of the side effects of chronic ingestion is polycythemia. By stabilizing hypoxia-inducible transcription factors that normally respond to low concentrations of oxygen, cobalt mimics hypoxia and stimulates erythropoietin production. In the 1950s, cobalt chloride was used to treat iron deficiency anemia. Some of these patients developed hypothyroidism and goiter because of cobalt's ability to inhibit tyrosine iodinase. In addition, cobalt has caused dilated cardiomyopathy with pericardial effusions in adults who consumed large amounts of beer in which cobalt salts had been added as a foam stabilizer. Cobalt can also cause neurotoxicity with symptoms of hearing loss, visual impairment, and polyneuropathy.

Because cobalt is no longer used as a therapeutic or as an additive to beer, the concern for cobalt toxicity is now isolated to patients with cobalt-chromium prosthetic joints.[11] Cobalt liberated from a prosthesis has been linked to hypothyroidism, dilated cardiomyopathy, and neurotoxicity with metal-on-ceramics arthroplasty and metal-on-metal prosthetics. When it is viewed in the context of the millions of prosthetic joints placed each year and the few reported cases, this complication seems rare. The diagnosis in a patient with a cobalt-containing joint replacement requires symptoms of polycythemia, hypothyroidism, cardiomyopathy, and neurotoxicity. In these patients, a blood chromium level above 7 μg/L should stimulate a referral for a possible joint revision. There is little evidence that chelation improves outcomes in cobalt-poisoned patients.

Silver (Argyria)

Silver (Ag) is a precious metal long used in coinage and for its antibacterial properties. Silver is a broad-spectrum antimicrobial and commonly used as a topical antimicrobial in bandages, catheters, and medical devices. The ingestion of colloidal silver preparations as a "natural" supplement accounts for the majority of recent cases of significant toxicity.

When it is ingested continually, silver will be deposited in the skin and the liver.[12] The primary chronic toxicity of silver is argyria, which is a permanent blue-gray discoloration of the skin due to silver deposition over time (Fig. 22-1). Argyria can result from inhalation, ingestion, mucosal absorption, or dermal application or exposure. Argyria may be localized to the site of exposure, such as with corneal argyria, which was seen in the past from the use of colloidal silver-containing eye drops, or at the site of silver earrings and rings. Rarely, argyria has been reported after the implantation of silver-containing medical devices.

FIGURE 22-1. Frontal and side views of a 36-year-old woman with argyria show the gray discoloration of her face and neck. (From Jacobs R. "Argyria: my life story," *Clin Dermatol.* Elsevier, 2006;24:66-69. Figure 3).

The diagnosis of argyria is primarily based on history and physical examination. Localized skin biopsy, typically to differentiate argyria from malignant lesions, will show characteristic black-brown globules that are adherent to the dermal elastic fibers, blood vessels, basement membranes, hair follicles, and sweat glands on light microscopy; refractile particles on darkfield microscopy; and the presence of silver on scanning electron microscopy with energy dispersive radiography.

Chelation therapy is not effective for argyria, but successful laser treatment has been reported.[13]

Thallium (Neuropathy and Alopecia)

Thallium (Tl) has no beneficial role in the human body. Its salts are odorless, tasteless, well absorbed in the gastrointestinal tract, and very toxic. These characteristics make it a potential homicidal agent, and patients with thallium poisoning should always be considered victims of a crime. By interfering with potassium and sulfhydryl-containing enzymes, thallium interrupts normal energy production. Although it is toxic to all organs, the peripheral nervous system and integumentary system are the most sensitive.

The earliest clinical sign of thallium poisoning is a rapidly progressive, painful sensory polyneuropathy. Within 2 or 3 days of exposure, patients will describe painful burning paresthesias in their feet. These paresthesias can progress up the legs and, over time, can involve the hands. Motor nerves can also be affected, and profound weakness, including in respiratory muscles, can be misdiagnosed as Guillain-Barré syndrome (Chapter 420). Cranial neuropathies have also been reported. The best-known complication of thallium is painless hair loss, typically beginning 5 to 14 days after exposure and sometimes progressing to total body alopecia. Skin and nails can also be affected, with scaling of palms, acne-like lesions of the face, and Mees lines in the nails. Other neurologic symptoms of thallium poisoning include hallucinations, altered mental status, insomnia, psychosis, ataxia, and coma. Constipation, myalgias, pleuritic chest pain, arrhythmias, and hypotension can also occur.

Because systemic toxicities often develop before hair loss and because not all patients lose their hair, clinicians should consider thallium as a possible cause of any rapidly progressive painful neuropathy. In patients with thallium poisoning, a pulled hair will often have darkening of the hair root when it is visualized under a low-power light microscope. The definitive diagnosis of thallium poisoning requires the identification of elevated concentrations of thallium in a 24-hour urine sample (normal, <20 μg/specimen). As thallium undergoes enterohepatic circulation and is eliminated in the feces, treatment requires binding of thallium in the gut. The most effective antidote is Prussian Blue (a complex of potassium hexacyanoferrate), with recommended doses ranging from 3 g orally three times a day up to 250 mg/kg three times a day.[14]

Zinc (Myelopathy)

Zinc (Zn) is an essential mineral that is necessary for normal cellular functioning. It is involved in the catalytic activity of more than 100 enzymes and plays an important role in olfaction, taste, immune function, protein synthesis, and DNA synthesis. It is found naturally in a wide variety of foods and is absorbed in the jejunum, where it binds to metallothioneins. Zinc deficiency is manifested as a triad of dermatitis, diarrhea, and alopecia, which is reversible after zinc repletion.

In the setting of zinc overload, metallothioneins are upregulated; because copper has a higher affinity for metallothioneins, the result is increased copper binding and subsequent elimination of copper. Zinc-induced copper deficiency has been reported after overuse of zinc-containing supplements, with the improper use of zinc-containing denture adhesives, and from the presence of retained zinc-containing coins such as pennies.

The hematologic manifestations of zinc-induced copper deficiency include sideroblastic anemia, leukopenia, neutropenia, and myelodysplastic syndrome,[15] all of which are reversible with zinc cessation alone. In addition, a syndrome of myeloneuropathy, characterized by a spastic gait and sensory ataxia, is also associated with zinc overload/copper deficiency and may improve with copper supplementation and zinc cessation.

Diagnostic testing in patients suspected of zinc overload should include serum or urine zinc concentrations (Table 22-1), serum copper levels, and ceruloplasmin levels. In patients with myeloneuropathy, nerve conduction studies may show a sensory neuropathy, and magnetic resonance imaging (MRI) may show increased T2 signal in the cervical cord. Treatment of zinc overload–induced copper deficiency is primarily by cessation of zinc exposure and repletion of copper, such as with 6 mg/day of elemental copper

orally daily for the first week, then 4 mg/day for the next week, and finally 2 mg/day after that until serum levels return to normal. Various chelation regimens have been reported, but data are insufficient to support their routine use in the setting of chronic toxicity.

Manganese (Parkinsonism)

Manganese (Mn) is an essential element necessary for the function of several enzymes, including superoxide dismutase and glutamine synthetase. Although there is no clear syndrome associated with manganese deficiency, a well-described constellation of symptoms and findings is associated with manganese toxicity. Associated primarily with chronic occupational exposure, manganese toxicity results from inhalation of high concentrations of either manganese dust (e.g., in miners) or manganese fumes (e.g., smelting, grinding, and rarely welding).[16] More recently, manganese toxicity has been reported in abusers of methcathinone, when this drug was illegally synthesized with potassium permanganate. Although the mechanism is not clear, manganese causes selective toxicity in the globus pallidus, striatum, and substantia nigra pars reticulata. In contrast to idiopathic Parkinson disease (Chapter 409), manganese does not affect the substantia nigra pars compacta.

The symptoms of manganism develop insidiously after years of exposure. Patients first develop changes in appetite, muscle weakness, and apathy. On occasion, patients will develop signs of central excitation and can have what is termed manganese psychosis. Symptoms often progress to difficulties with gait, speech, and facial expression. The gait abnormalities involve a slow and clumsy gait with the inability to walk backward. Patients often freeze while turning and frequently fall. Symptoms can progress to muscle hypertonia in extension and a peculiar gait in which patients walk on the balls of the feet with their ankles extended. Patients also develop stuttering speech, masked facies, sleep disturbances, and myalgias. Unlike with idiopathic Parkinson disease, manganese-exposed patients do not typically develop a resting tremor, and these symptoms are almost always symmetrical at onset.

Although there is no definitive test of manganese toxicity, a history of exposure, confirmatory laboratory testing (Table 22-1), radiographic studies, and clinical symptoms can support the diagnosis. The best laboratory test is a whole blood manganese level (normal, <15 μg/L), with elevated levels indicative of exposure but not necessarily correlating directly with symptoms. Because manganese can concentrate in the globus pallidus, MRI often will show an intense T1-weighted signal in the globus pallidus bilaterally. As with blood, however, MRI is indicative of manganese exposure but does not correlate with clinical symptoms. Because of the differences in the affected brain regions between manganese toxicity and Parkinson disease, fluorodopa positron emission tomography (PET) scanning can help differentiate between these disorders: patients with manganese toxicity will typically have normal PET scans, whereas patients with Parkinson disease have abnormal scans.

Manganism is not typically responsive to treatment. Although chelation with $CaNa_2EDTA$ has been associated with increased urinary elimination of manganese, there are no convincing data as to whether patient outcomes are improved.

REVIEW QUESTIONS

1. A 58-year-old patient seeks your care for management of his hypertension. In his evaluation, you discover that he operates a gun range and often cleans up casings at the end of the day. You request a blood lead level that comes back elevated at 60 µg/dL. He has no other medical complaints. Along with pharmacologic management for his hypertension, which of the following lead treatment strategies would be the most efficacious?

A. Chelation with BAL and CaNa2EDTA
B. Chelation with DMSA
C. Chelation challenge, and if the 24-hour urine level is above 100 µg per gram of creatinine, chelate with DMSA
D. No intervention is warranted.
E. Proper respiratory protection at work and repeat lead levels in 1 month

Answer: E Adults who are asymptomatic and have blood lead levels below 70 µg/dL require no treatment besides removal of the source of exposure and decrease in workplace exposure through proper respiratory protection.

2. A 38-year-old health-conscious man is referred to you for arsenic poisoning. He has been seeing his primary care physician for symptoms of mild depression. He asked his physician to check him for heavy metal poisoning because he has well water and read that lead could cause symptoms similar to his. A 24-hour urine test result showed lead and mercury levels to be within normal limits but revealed an extremely elevated urine arsenic level (530 µg per gram of creatinine). What is the most prudent next step?

A. Admit him to the hospital and immediately begin chelation with DMSA.
B. Ask about any history of seafood ingestion and send his urine for arsenic speciation.
C. Begin outpatient treatment with DMSA and repeat testing in 3 weeks.
D. Obtain blood arsenic levels to determine if he has had a recent exposure.
E. Obtain hair arsenic levels to determine if he has had a remote exposure.

Answer: B Organic arsenic is considered largely nontoxic to humans. Found in shellfish and seafood, it is a common cause of elevated urinary arsenic levels. In patients without symptoms of acute arsenic poisoning, a detailed history of seafood ingestion and sending a urine sample for speciation of arsenic would be the next step.

3. A 32-year-old chemical worker ingests a vial of methylmercury in a suicide attempt. She is admitted to the hospital, lavaged, and begun on DMSA chelation. The development of which of the following symptoms would concern you the most in respect to her long-term outcome?

A. Hypertension and tachycardia
B. Myalgias
C. Prolonged QTc on her electrocardiogram
D. Proteinuria
E. Visual field constriction and perioral numbness

Answer: E The most devastating effect of organic mercury intoxication is neural degeneration. Early symptoms of this include constriction of visual fields, tremor, and paresthesias. Symptoms can progress to ataxia and ultimately to encephalopathy and death. Elemental mercury exposure can mimic pheochromocytoma and can be manifested with muscle weakness and myalgias; these symptoms can improve when the source of mercury exposure is removed. Proteinuria would be a potential manifestation of inorganic mercury toxicity, but renal damage tends to resolve over time. Arsenic, not mercury, is associated with a prolonged QTc.

4. A 68-year-old Hispanic woman with end-stage renal disease requiring hemodialysis three times a week develops a progressive encephalopathy. The water used for dialysis was tested and found to be normal. Which one of the following would you think is most responsible for her symptoms?

A. Occasional use of Pepto-Bismol
B. A prosthetic hip joint
C. Her sucralfate prescription
D. The homeopathic use of colloidal silver
E. Traditional Hispanic folk remedy for gastrointestinal distress

Answer: C Sucralfate is most likely to cause encephalopathy in a dialysis patient from aluminum toxicity. A prosthetic hip with cobalt has been linked to cardiomyopathy and hypothyroidism. Pepto-Bismol can cause a progressive encephalopathy but typically only after prolonged and regular use. Hispanic folk and Chinese herbal medicines can occasionally contain arsenic and elemental mercury, but either would be less likely to cause the patient's symptoms. Colloidal silver ingestion typically affects only the skin.

EPIDEMIOLOGY OF AGING: IMPLICATIONS OF AN AGING SOCIETY

ANNE B. NEWMAN AND JANE A. CAULEY

DEMOGRAPHY: AGING OF SOCIETIES WORLDWIDE

More than 40 million adults older than 65 years are now living in the United States, and they account for 13% of the population. Even more notably, 5.5 million people (1.8% of the population) are older than 85 years, and more than 50,000 people (0.02% of the population) are older than 100 years. Although only 13% of the U.S. population is older than 65 years, they account for 36% of all medical expenditures.[1]

The trend toward an aging society has expanded to become a global health issue. The global population aged 65 years and older is more than 500 million people, about 7% of the world's population. By 2040, the world is projected to have 1.3 billion older people, accounting for 14% of the total population. In 2040, 28% of the population in western Europe will be 65 years and older, including about 9.3% older than 80 years. Japan is currently the oldest country in the world, with 22% of the population aged 65 years and older, compared with 18% in western Europe and 21% in North America (Table 23-1). Between 2005 and 2040, the overall world population is projected to increase by 35%, whereas the percentage aged 85 years or older will increase by 300% and the percentage aged 100 years or older will increase by 750%. The estimated number of centenarians was about 270,000 in 2005, but this number is projected to reach 2.3 million by 2040.[2]

Population aging, which has been accelerating in the United States and western Europe for more than 100 years, is now affecting countries such as India and China, where the population older than 65 years is projected to increase more than three-fold by 2040. The population aged 65 years and older was already 166 million in China and India in 2008, nearly one third of the world's total, and the absolute number will increase to 550 million by 2040. In the United States, increases in the elderly population are most prominent in minorities, especially Hispanics.

Life expectancy is also changing dramatically. Life expectancy is highest in Japan at 82 years and is in the 78- to 80-year range for other developed countries. Life expectancy has continued to increase at all ages and especially for people older than 85 years, except in some parts of the developing world, such as sub-Saharan Africa, where HIV/AIDS has had a major negative impact. In the United States, an average 65-year-old woman can expect to live for an additional 19.6 years, and the average 65-year-old man can expect to live for an additional 16.8 years. These changes have many important impacts on society because rates of illness and disability increase with age, and the relative proportion of younger adults who can help care for this older population is not increasing.

THE HEALTH OF OLDER ADULTS

Mortality

The current generation of older adults is healthier than previous generations because of the successful elimination of many infectious diseases and the prevention of injuries, but the population at risk for chronic diseases is increasing. In the United States in 1900, infectious diseases accounted for the largest share of deaths after 65 years of age, whereas heart disease, cancer, stroke, and lung disease account for more than half of all deaths today.

As people age, their mortality rate increases. Death rates are 1.8% per year in men and 1.2% per year in women between the ages of 65 and 70 years, increasing to 13% per year in women and 15% per year in men older than 85 years.[3] With increasing age, causes of death in older adults shift away from cancer and cardiovascular disease and toward stroke and dementia. Nevertheless, cardiovascular disease and cancer remain the top two causes of death in older adults into advanced old age (Table 23-2).

However, many factors contribute to mortality in old age, and death is usually multifactorial, with contributions from other chronic underlying conditions. Mortality in older adults is related to sociodemographic status and health habits; cardiovascular risk factors; and pulmonary, vascular, kidney, physical, and cognitive function. The inflammatory marker interleukin-6 is consistently associated with death from many different primary causes, thereby suggesting that inflammation is a common underlying pathway to death.[4]

Morbidity

The most common chronic conditions in older adults are hypertension, high cholesterol levels, and ischemic heart disease (Fig. 23-1). Prevalence varies by sex, with men having more heart disease than women and women having more arthritis than men. Because women live longer than men do, the prevalence of dementia is higher in women than in men, but incidence rates are more similar. Older African Americans and Hispanics have higher rates of hypertension, diabetes, and metabolic syndrome compared with older whites.[5]

The majority of older adults have one or more chronic health conditions, and 50% have two or more. Because of this high prevalence of multiple conditions, the care of older adults requires a balanced approach that considers the impact of treatment of one condition on the other conditions and the potential that some conditions may be masked by multiple overlapping symptoms. The presence of multiple conditions is commonly referred to as comorbidity, although multimorbidity may be a more accurate term.

Multimorbidity is strongly associated with disability, with a stepwise increase in the proportion of individuals who have self-reported difficulty in activities of daily living according to their number of medical conditions. Prospectively, the number of comorbid conditions predicts future disability. Multimorbidity also is associated with having a slower gait speed and poorer lower extremity strength and balance. Furthermore, disability and comorbidity provide distinct information and should not be considered equivalent constructs. The combined influence of multiple chronic diseases on physical functioning can be greater than the simple sum of their effects.

Subclinical Disease

Subclinical diseases are also common and increasingly recognized as important contributors to the risk of disability and mortality. With the advent of noninvasive functional testing and imaging, it is clear that many conditions can be advanced in older people, even if they are not symptomatic. Symptoms may also be nonspecific and attributed to aging rather than to underlying disease. For example, population studies of cardiovascular disease reveal that strokes are present on magnetic resonance imaging in about one third of older adults with no history of stroke, and advanced atherosclerosis is present also in one third of older adults with no history of a prior myocardial infarction. Ankle-brachial index screening documents that peripheral artery disease is 5 to 10 times more common than classic intermittent claudication. Other conditions, such as chronic obstructive pulmonary disease and osteoarthritis, are also more common when noninvasive testing is performed compared with clinically diagnosed disease. Importantly, subclinical disease burden is strongly related to mortality.

Obesity

Obesity (Chapter 220) is increasing in older adults at a rate faster than in any other age group. Obesity and disability disproportionately affect women and especially women of color. About one third of whites older than 60 years are obese, compared with about 50% of blacks and 40% of Hispanics. Obesity has a major impact on disability, including difficulty in walking or climbing steps. The epidemic of obesity is also contributing to the large increases in the incidence of diabetes in older adults. Increasing rates of obesity may halt or reverse increases in life expectancy, reduce quality of life, and increase disability.

Geriatric Syndromes

Many multifactorial conditions in older adults do not fall into a single disease category and are called geriatric syndromes. For example, urinary incontinence (Chapter 26) is a functional loss of bladder control that can be influenced by poor mobility, poor vision, loss of urinary concentrating ability, and certain medications as well as impaired bladder structure or function. Other important geriatric syndromes include impaired sleep (Chapter 405), delirium (Chapter 28), falling (Chapter 25), and weight loss. Rather than focusing on identification of a primary cause, all contributing factors need to be addressed in the evaluation and treatment of these syndromes.

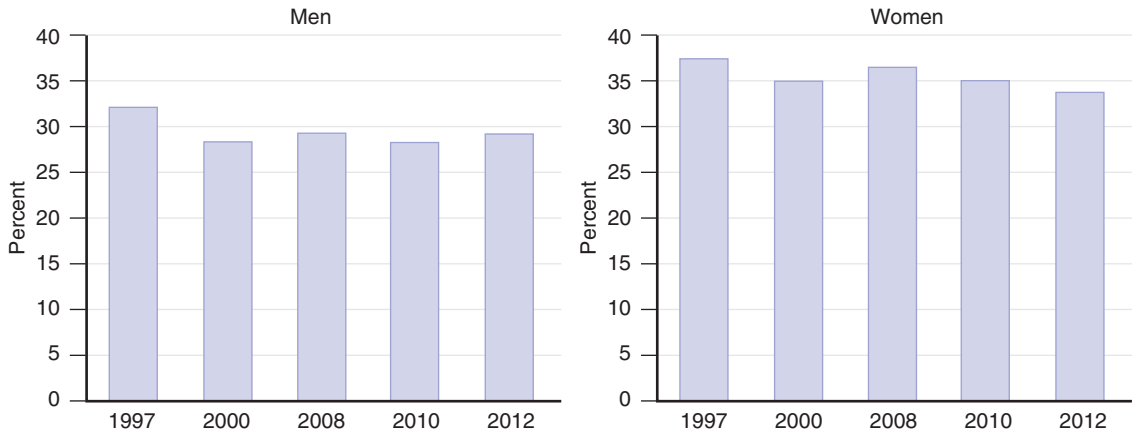

FIGURE 23-1. Prevalence of complex activity limitation among those 65 years and older in the United States. A complex activity limitation is defined as having one or more of the following limitations: self-care (activities of daily living or instrumental activities of daily living), social, or work. (Source: Centers for Disease Control and Prevention, National Center for Health Statistics: Health, United States, 2012, and Health, United States, 2010. Disability

In older adults, disability is usually related to multiple chronic conditions. Disability can be slowly progressive and chronic, or it can be sudden and catastrophic, as in the case of a stroke or hip fracture. Levels of disability include loss of basic self-care skills, such as bathing and toileting; loss of ability to live in the community for skills such as shopping and paying bills; loss of mobility; and loss of ability to function in high-level tasks. Classification schemes for disability in geriatrics are reviewed in Chapter 24.

The majority of older adults are not disabled. Data from the National Health Interview Survey show that disability levels declined in the 1980s and 1990s but have largely plateaued in recent years (Fig. 23-2). In 2012, about 28% of men and 34% of women older than 65 years reported difficulty with complex activities. Disability for activities of daily living appears to be declining worldwide, although evidence suggests that less severe levels of disability are becoming more common. It is possible, however, that the obesity epidemic will result in more years with disability.

Frailty versus Vigor

Frailty has been described as a state of decreased physiologic reserve and increased vulnerability to stress. Frailty is a wasting syndrome characterized by weakness, fatigue, low activity, slow movement, and weight loss. It has also been characterized by poor physical function alone or by a high burden of chronic disease. By the definition of a wasting syndrome, frailty is present in 7% of community-dwelling adults aged 65 years and older and 25% of adults aged 85 years and older. These estimates undoubtedly underestimate the prevalence of frailty because frail individuals are more likely to be temporarily in a medical care facility and unable to participate at any given time.

Loss of muscle mass, or sarcopenia, is an underlying component of frailty,[6] but excess fat, especially visceral fat and muscle fat, has a greater influence on physical function, inflammation, and metabolism than does low muscle mass. In the elderly, muscle strength, including contractile force, mitochondrial function, and speed of contraction or power, is more important to physical

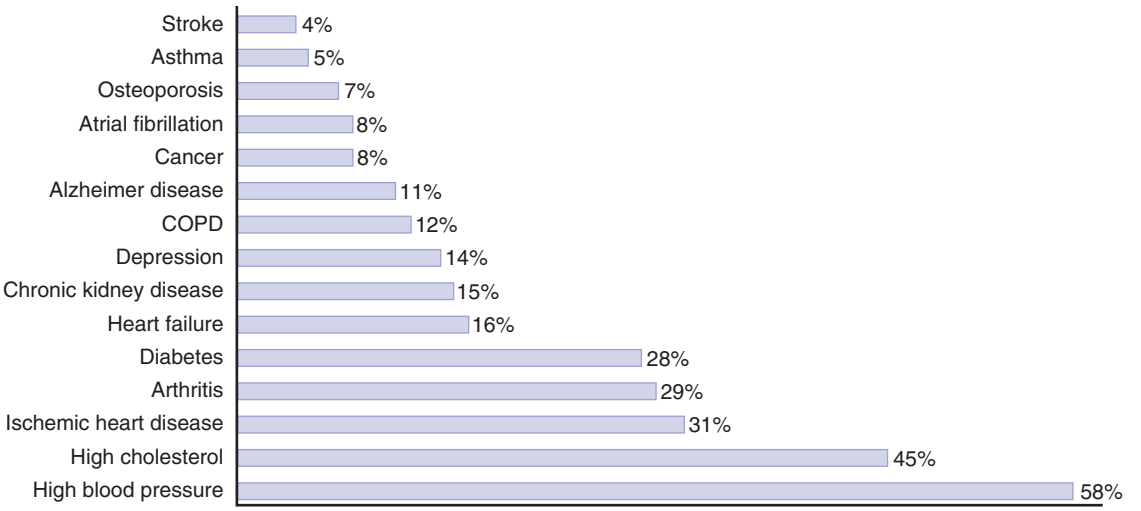

FIGURE 23-2. Percentage of Medicare fee-for-service beneficiaries with 15 selected chronic conditions: 2010. (Source: Centers for Medicare and Medicaid Services: Chronic Conditions among Medicare Beneficiaries, Chartbook: 2012 Edition. Based on 2010 Centers for Medicare and Medicaid Services administrative claims data for 100% of Medicare beneficiaries enrolled in the fee-for-service program.) COPD = chronic obstructive pulmonary disease.

function than muscle mass. Important weakness can be assessed in an office setting by measuring a grip strength (<30 kg in men and <20 kg in women).

Longevity and Healthy Aging

About 20 to 30% of longevity is heritable, similar to many complex chronic diseases.[7] Animal models of aging show that lifespan can be extended several-fold by altering genes, especially in the metabolic pathway. In lower organisms and mice, calorie restriction, achieved through long-term daily restriction of available calories, extends life, but this approach has mixed results in primates. Many hormonal factors are reduced with aging, but hormone replacement with estrogen, growth hormone, testosterone, and adrenal androgens is not beneficial for longevity and may be harmful. Among genetic factors, absence of the *ApoE4* allele remains the most robust predictor of longevity, and recent genome-wide association studies of centenarians also point to genes such as *FOX03A* in the pathway for metabolic control.

Many health conditions in late life may stem from early life exposures, including the health of the mother during pregnancy. For example, low birthweight or famine during pregnancy predicts early cardiovascular disease and diabetes when babies are later exposed to higher calorie intake. In Sweden, a lower lifetime exposure to infectious disease was associated with increased life expectancy. More research is needed to determine the critical periods for development and the optimal environmental exposures that can enhance healthy aging later in life.

PREVENTION

Osteoporosis treatment is effective in reducing fracture risk in advanced old age,[8] and treatment of hypertension is effective in decreasing mortality after 80 years of age.[A1] Statins are effective in reducing coronary heart disease in older adults.[A2] Physical activity significantly decreases the risk of disability[A3] and may reduce the risk of dementia, although the latter finding is primarily from observational studies that may be confounded by the fact that healthier people are more able to exercise. Ongoing research is evaluating the potential for aspirin to prolong active life in older adults and whether testosterone replacement in hypogonadal men will improve physical, cognitive, or sexual function in older men.

GERIATRIC ASSESSMENT

DAVID B. REUBEN

Geriatric assessment is a broad term used to describe the evaluation of older patients, a process that recognizes the diverse medical and psychosocial conditions that influence the health status of older persons. In addition to the diseases that are common in the elderly population, these influences include social, psychological, and environmental factors. Geriatric assessment can range from brief screens by individual clinicians to an intensive interdisciplinary process that includes both evaluation and management.

Three fundamental concepts guide geriatric assessment and the resulting medical management. At the core of geriatric assessment is functional status, both as a dimension to be evaluated and as an outcome to be improved or maintained. A second overarching concept guiding geriatric assessment is prognosis, particularly life expectancy. Finally, geriatric assessment must be guided by the patient's goals.

FUNCTIONAL STATUS

Functional status can be viewed as a summary measure of the overall impact of health conditions in the context of an elderly person's environment and social support network. The underlying framework of functional status is a hierarchy of increasing complexity, beginning with specific physical movements (e.g., lifting, walking) that are integrated into higher level activities (e.g., fulfilling occupational and social roles). Impairment of functional status can be triggered by the onset of disease, deconditioning, changes in social support or environment, and advanced age.

Most commonly, older adults' functional status is assessed at two levels: activities of daily living (ADLs) and instrumental activities of daily living (IADLs). ADLs refer to self-care tasks such as bathing, dressing, toileting, maintaining continence, grooming, feeding, and transferring. Dependency in these tasks, which is present in up to 10% of older persons, usually requires full-time help at home or placement in a nursing home.

IADLs refer to tasks that are integral to maintaining an independent household, such as using the telephone, doing laundry, shopping for groceries, driving or using public transportation, preparing meals, taking medications, performing housework, and handling finances. Dependency in IADLs is more common, and almost 20% of persons aged 75 years or older are impaired in at least one task. With the progressive loss of multiple IADL functions, older persons find it more difficult to remain in their homes. Accordingly, many social services (e.g., Meals On Wheels, homemaker

TABLE 24-1 LIFE EXPECTANCY IN VARIOUS STATES OF FUNCTIONAL HEALTH ACCORDING TO AGE, GENDER, AND INITIAL FUNCTIONAL STATUS*

*Using 1988-1990 Established Populations for Epidemiologic Studies of the Elderly Data
ADL (activities of daily living) disabled = self-report of being unable to do or requiring human help to perform any of the following: bathing, transferring from bed to chair, dressing, eating, and using the toilet. Mobility disabled = self report of being unable to walk a half-mile or to walk up and down stairs to the second floor without help.

services, transportation services) are available to compensate for these deficiencies. A move to an assisted living facility can provide most IADL functions, but many facilities do not routinely provide assistance with ADLs except at an additional cost. In the United States, the costs of assisted living facilities are not covered by Medicare.

At a higher level of function, advanced activities of daily living (AADLs) refer to the ability to fulfill societal, community, and family roles as well as to participate in recreational or occupational tasks. These advanced activities vary considerably from individual to individual but may be valuable in monitoring functional status before the development of disability.

The choice of functional assessment tool depends on the characteristics of the population being assessed. For example, nursing home residents are almost always completely dependent in IADLs, so the focus should be on assessing ADLs and other basic dimensions of health. Hospitalized older persons should be assessed with regard to their prehospitalization functional status to provide insight into what may be achievable as well as their functional status at the time of discharge to identify any existing gap and to facilitate plans to close it.

Functional status is usually measured by self-report or proxy report. However, physical and occupational therapists often add objective information using structured clinical examinations or assessments. In addition, dimensions such as mobility and balance that contribute to function can be assessed by objective measures (described later).

Functional status should be assessed periodically: at the time of an initial visit; after a major illness; and at the time of social milestones, such as the illness of a spouse or a change in living or working situation. Changes in functional status should always prompt further diagnostic evaluation and intervention unless the change is expected and reflects a trajectory that is consistent with the patient's wishes. Measurement of functional status can be valuable in monitoring response to treatment (especially of chronic diseases) and can provide prognostic information that is useful in planning short- and long-term care.

PROGNOSIS

Life expectancy affects both the assessment process and the management decisions based on that assessment. For some older patients, comorbidities can worsen prognosis, such that screening tests (e.g., mammography) and treatments (e.g., for hypertension) with demonstrated effectiveness would not be beneficial within the expected survival period.

The probability that a patient will survive for a specified time (e.g., 5 years from the time of the assessment) or to a specified age (e.g., to age 100 years) can be estimated on the basis of age, gender, and race with government-generated life tables. Life expectancy also can be estimated with online calculators (see, for example, *eprognosis.org*) or by incorporating clinical characteristics. For example, better cognitive status and less comorbidity are the best predictors of 5-year survival in nonagenarians.[1] One simple approach is to incorporate functional status in addition to age and gender (Table 24-1).[2,3]

PATIENT GOALS

As people age, their current and future health may become a prominent factor in determining and achieving their life goals. Among very old patients, goals may be limited to achievement of a functional or health state (e.g., being able to walk independently), control of symptoms (e.g., pain, dyspnea), maintenance of their living situation (e.g., remaining at home), or short-term survival (e.g., living long enough to reach a personal milestone, such as an upcoming holiday). Sometimes the goals of patients and physicians differ. For example, a patient may want a cure, whereas the physician believes that only symptom management is possible. Conversely, the physician may believe that a better outcome is possible, but the patient declines to pursue the recommended path (e.g., hip replacement to restore mobility).[4] Physicians and patients alike must recognize that the elderly may receive less benefit from some interventions than younger do patients because of other adverse prognostic factors. For frail older persons with multiple chronic conditions or a short life expectancy, clinicians and patients should work together to identify the patient's personal goals within and across a variety of dimensions (e.g., symptoms, physical functional status, social and role functioning).[5] The care plan can then be developed and framed in the context of meeting these goals.

COMPONENTS OF GERIATRIC ASSESSMENT

Geriatric assessment begins with a medical evaluation. Some aspects (described later) that are rarely abnormal in younger adults (e.g., mobility, cognition) may cause substantial morbidity in older persons. In addition, some clusters of abnormal findings, such as muscle wasting, poor hygiene, bruises, pressure sores, and contractures, should raise the suspicion of elder mistreatment, neglect, or abuse. In such cases, patients should be questioned and examined without family members or caregivers present. Patients should then be queried as to whether anyone has threatened or hurt them, whether they have been receiving enough care, and whether anyone has taken their things. Answers to these questions may provide confirmatory information and prompt a report to adult protective services.

Nonmedical assessments are also important because they can identify problems that should be addressed and may be key to achieving the patient's goals. In addition to an assessment of functional status, older persons' environmental, financial, and nonfinancial support should be assessed. In some situations, particularly when older persons become acutely ill or experience

caregiver stress or loss of a loved one, assessment of spiritual needs, with appropriate referral, may be valuable.

Advance Directives

Clinicians should discuss older patients' preferences for specific treatments while they still have the cognitive capacity to make these decisions. Patients should be asked to identify a spokesperson to make medical decisions for them if they cannot speak for themselves. This information should be conveyed through a durable power of attorney for health care, which also allows patients to specify treatments they do not want. Many states have allowed the use of Physician Orders for Life-Sustaining Treatment (POLST), a specific advance directive that documents a patient's end-of-life treatment preferences and serves as an order sheet. The standardized form, which is signed by both the physician and the patient, must be honored in all settings of care, including by emergency medical technicians responding to 911 calls.

Medical Assessment

The medical assessment includes vision; hearing; cognition; mood and affect; falls, mobility, and balance; medication review; nutrition; and urinary incontinence. Numerous screening instruments have been developed that assess many of these dimensions. Another important medical component of geriatric assessment includes[5] a determination of whether preventive services are up-to-date.

Vision

Each of the four major eye diseases—cataract, age-related macular degeneration, diabetic retinopathy, and glaucoma (Chapter 423)—increases in prevalence with age. Moreover, presbyopia is virtually universal, and most older persons require eyeglasses. Visual impairment has been associated with increased risk of falls, functional and cognitive decline, immobility, and depression.[6] Corrective lenses or other treatments may restore vision or prevent further decline of visual function.

A single question can be used to screen for visual impairment: Do you have difficulty driving, watching television or reading, or doing any of your daily activities because of your eyesight, even while wearing glasses?

The Snellen eye chart is the standard method of screening for visual acuity. The patient is asked to stand 20 feet from the chart and to read letters. Inability to read letters on or below the 20/40 line with the best-corrected vision (using glasses) indicates the need for further evaluation.

Hearing

Hearing loss (Chapter 428), which affects more than 60% of community-dwelling adults older than 70 years and 75% of residents living in nursing home settings, is associated with reduced cognitive, social, emotional, and physical functioning. When hearing loss is detected, amplification by hearing aids or assistive listening devices can improve quality of life and functional status.[7]

To identify hearing loss, simple questions (e.g., Would you say you have any difficulty hearing? Do you feel you have hearing loss?) can be asked, or the 10-item self-reported Hearing Handicap Inventory for the Elderly instrument can be administered. If either of these screens is positive or if the clinician suspects hearing loss, an objective test is the whisper voice test, which involves whispering three different random words in each ear at distances of 6, 12, and 24 inches from the patient's ear and then asking the patient to repeat the words. Patients who fail the test—that is, are unable to repeat half the whispered words correctly—should be referred to an audiologist for further evaluation.

A more accurate screening tool for hearing impairment is the Welch Allyn AudioScope. This handheld otoscope has a built-in audiometer that can be set at different levels of intensity. A pretone at 60 dB is delivered to the patient, and then four tones of 500, 1000, 2000, and 4000 Hz at 40 dB are presented. The inability to hear either the 1000- or 2000-Hz frequency in both ears or both the 1000- and 2000-Hz frequencies in one ear indicates a positive screen and identifies the need for formal audiometric testing.

Cognitive Assessment

The incidence of dementia (Chapters 27 and 402) increases with age, especially among those older than 85 years. Early detection of memory problems can lead to the identification of treatable conditions that contribute to cognitive impairment and the development of a proactive management plan with the patient's full participation.[8] Because the diagnosis of dementia has not been documented for as many as 80% of patients who meet diagnostic criteria for it, clinicians should routinely evaluate elderly patients using any of a variety of brief screening instruments (Chapter 27).[9]

Another component of cognitive assessment is decision-making capacity. In cognitively intact older persons, capacity is assumed. However, among those with cognitive impairment, decision making must be determined before many treatments are initiated. As a rule, capacity is specific to the decision the patient is being asked to make. Ask the following questions to determine a patient's decision-making capacity:

- Can the patient make and express personal preferences at all?
- Can the patient comprehend the risks and benefits?
- Does the patient comprehend the implications?
- Can the patient give reasons for the alternative selected?
- Are supporting reasons rational?

If the answer to all these questions is yes, the patient is competent to make the decision at hand. If not, a surrogate (the durable power of attorney for health care, if the patient has identified one) should make the decision. If a durable power of attorney for health care has not been identified, the decision can be made by a family member, friend, or caregiver who knows the patient well. The order of surrogates is determined by state law. If no one is available, the health care provider should make the decision on the basis of the patient's known value system or what the health care provider believes to be in the best interest of the patient.

Mood and Affect

Although major depression (Chapter 397) is no more common among the elderly than among the younger population, minor depression and other affective disorders are common and cause considerable morbidity. Moreover, the clinical manifestations of depression may be atypical, and depression may be masked in patients with cognitive impairment or other neurologic disorders such as Parkinson disease (Chapter 409).

A two-item version of the Patient Health Questionnaire can effectively screen for depression symptoms.[10] The screener asks the patient: Over the past 2 weeks, how often have you been bothered by any of the following problems?

- Little interest or pleasure in doing things
- Feeling down, depressed, or hopeless

Responses are scored as follows: 0, not at all; 1, several days; 2, more than half the days; 3, nearly every day. Persons who score a total of 3 points or higher on the two-item screen have a 75% probability of having a depressive disorder and should be evaluated in more detail (see Table 27-3 and Chapter 397).

Falls, Mobility, and Balance

Approximately one third of community-dwelling persons older than 65 years and half of those older than 80 years fall each year. Ten percent of these falls result in a serious injury. Patients who have fallen or have gait or balance problems are at higher risk of another fall. Performing a falls assessment (measuring orthostatic blood pressure; assessing vision; reviewing medications; and testing balance, gait, and lower extremity strength) and treating risk factors for falling can reduce falls by 30 to 40%.

All older patients should be asked at least annually if they have fallen,[11] and frail older persons should be asked about falls at every visit. In addition, asking about fear of falling can identify patients at risk of future falls.

Patients who have fallen or have a fear of falling should have their balance and gait assessed by direct observation of their ability to perform specific tasks. Tests of balance include the ability to maintain a side-by-side, semitandem, and full-tandem stance for 10 seconds; resistance to a nudge; and stability during a 360-degree turn. Quadriceps strength can be assessed by observing an older person rising from a hard armless chair without using his or her hands.

In addition, direct qualitative and quantitative observation of gait to determine stability is a quick and important component of assessment.[12] Qualitative aspects include evaluation of hesitancy; sway; step length, height, symmetry, and continuity; and path deviation. Gait speed is also a helpful marker for recurrent falls. Patients who take more than 13 seconds to walk 10 meters (0.8 meter per second) are more likely to have recurrent falls and to have a shorter life expectancy.[13]

The timed up-and-go test combines some features of strength and gait. It is a timed test of the patient's ability to rise from a standard armchair, walk 3

meters (10 feet), turn, walk back, and sit down again. Patients who take longer than 20 seconds to complete the test should receive further evaluation.

Medication Review

Older persons often see several different health care providers who prescribe multiple medications that increase the risk for drug-drug interactions and adverse drug events. At a minimum, the clinician should review the patient's updated and accurate medication list at each visit. A good method of detecting potential problems is to have patients bring in all their medications (prescription and nonprescription) in their bottles. Entering a patient's medication list into commercially available computer drug interaction programs can help prevent adverse events. Many electronic health records also alert clinicians to potential drug interactions.

Nutrition

Malnutrition in older adults includes obesity (Chapter 220), undernutrition (Chapter 214), and specific vitamin deficiencies (Chapter 218). Obesity in older adults is defined as a body mass index (BMI) of 30 kg/m^2 or greater. High BMI is associated with poorer function and more comorbidities, such as type 2 diabetes mellitus (Chapter 229), osteoarthritis (Chapter 262), hyperlipidemia (Chapter 206), coronary artery disease (Chapter 52), and sleep apnea (Chapter 100).

At the initial visit, patients should be weighed and asked about weight loss in the previous 12 months. They should be weighed at all follow-up visits. BMI should be calculated on the initial visit and periodically thereafter (e.g., yearly or when a change in weight suggests the need to recalculate). Serum markers, including serum albumin, prealbumin, and cholesterol levels, are nonspecific indicators of nutritional status and can be affected by inflammatory states, physiologic stress, and trauma.

Weight loss of 4% or more during 12 months predicts increased mortality and should prompt an evaluation of medical (e.g., malignant disease, gastrointestinal disorders, hyperthyroidism, diabetes), psychiatric (e.g., depression, dementia), dental, and social or functional (e.g., poverty, inability to shop or to prepare meals) causes. In community-based older adults, a serum 25-hydroxyvitamin D level below 50 nmol/L (20 ng/mL) is associated with an increased risk for relevant clinical disease events.[14]

Urinary Incontinence

Approximately one third of community-dwelling older adult women have some degree of urinary incontinence (Chapter 26), and 75% of older men have abnormal urinary tract symptoms. Complications of incontinence include skin irritation, pressure ulcers, urinary tract infections, sleep disruption, and falls. Identification of urinary incontinence is important because effective behavioral and pharmacologic treatments are available.

A simple screen for urinary incontinence asks the following question: Have you had urinary incontinence (do you "lose" your urine) to the extent that it is bothersome and you would like to know how it can be treated? This may be valuable in determining which patients want further evaluation and therapy. Patients who answer yes should be asked how much urine is leaked, how much it interferes with daily life, and when the leakage occurs. Further evaluation and treatment depend on whether the incontinence is overflow incontinence, urge incontinence, or stress incontinence (see Table 26-3).

PREVENTIVE SERVICES

Preventive services include lifestyle advice, screening tests to detect asymptomatic disease, and vaccinations. Recommended adult immunization schedules for older adults include annual influenza vaccination, one-time pneumonia vaccination, one-time pneumococcal vaccination, one-time herpes zoster vaccination (even if the patient reports a past episode of herpes zoster), and tetanus toxoid vaccination every 10 years after receiving one dose of tetanus, diphtheria, and pertussis vaccination (Tdap). (Chapter 18).

To help the clinician decide what is appropriate for a specific patient, the U.S. Preventive Services Task Force has created an interactive website (*http://epss.ahrq.gov/ePSS/search.jsp*) with recommendations based on the patient's age, gender, tobacco use, and current sexual activity (Chapter 14). For younger elderly persons, recommendations include screening for blood pressure, diabetes (if blood pressure >135/80 mm Hg), hyperlipidemia, obesity, alcohol misuse, colorectal cancer (to age 75 years), vitamin D supplementation, and osteoporosis as well as breast cancer in women (to age 75 years), with appropriate counseling and treatment if these disorders are detected. Exercise or physical therapy is recommended to prevent falls in patients who are at increased risk. Aspirin may be recommended to prevent cardiovascular disease in this population. Other recommendations depend on patient-specific risk factors.

With increasing age, fewer preventive services are recommended because of limited life expectancy and greater comorbidities. Accordingly, some preventive measures (e.g., aspirin to prevent cardiovascular disease) and cancer screenings are not recommended in the very elderly. When the evidence base for preventive services is sparse, decisions should be individualized, on the basis of the patient's personal values, goals, and preferences.

NONMEDICAL ASSESSMENTS

Environmental Assessment

Assessing a patient's environment includes evaluating three components: the person's ability to access community services (e.g., getting to the bank and stores if the patient cannot drive), the safety of the physical environment, and the appropriateness of the living situation for the person's functional ability and cognitive status. A brief screen for safety of the physical environment can be accomplished by using a checklist that is in the public domain (*http://www.cdc.gov/ncipc/pub-res/toolkit/Falls_ToolKit/DesktopPDF/English/booklet_Eng_desktop.pdf*). For home-bound older patients, a home safety evaluation by a home health agency is more appropriate.

Social Support Assessment

When older persons become frail, the adequacy of their social support network may be the determining factor in whether they can remain at home or need institutionalization. A brief screen of social support includes taking a social history, including asking who would be available to help if the patient becomes ill. For patients with functional impairment, the clinician should ascertain who can help the patient perform ADLs or IADLs. Early identification of problems with social support can help avoid crisis situations if the patient has a sudden medical or functional decline. Caregivers should be screened periodically for symptoms of depression or caregiver burnout and referred for counseling or support groups if necessary.

Financial Assessment

Although clinicians do not have the training or expertise to explore financial resources in detail, knowing the patient's insurance status may be helpful. For example, patients with Medicaid coverage may qualify for additional medical or social support benefits. Some may be eligible for other state or local benefits, depending on their income. Others may have long-term care insurance or veterans' benefits that can help pay for caregivers, obviating the need for institutionalization.

A STRATEGIC APPROACH TO GERIATRIC ASSESSMENT FOR THE PRACTICING CLINICIAN

Although assembling an interdisciplinary assessment team is beyond the capability of most practitioners, even small group practices can use teamwork and simple practice design to perform geriatric assessments efficiently and comprehensively. These assessments can lead to local implementation of or referral to comprehensive care models that can improve the outcomes of elderly individuals with a variety of chronic conditions.[■■] Because of time constraints, screening is increasingly delegated to staff and to patients and their families by standing orders, forms, and questionnaires (Table 24-2). For example, previsit questionnaires can be used to gather information about past medical and surgical history; medications and allergies; social history, including available social support resources, preventive services, ability to perform functional tasks, and need for assistance; home safety; and advance directives. In addition, the previsit questionnaire can include specific questions that assess vision, hearing, falls, urinary incontinence, and depressive symptoms. A reasonable approach is to assess these issues annually beginning at age 75 years. Persons who are younger than 75 years but have multiple comorbidities should also be screened and reassessed annually. In addition, some elements of geriatrics assessment (assessing ADLs and IADLs; gait, balance, and falls; mood and affect; and cognition) should be performed after major illnesses, especially for those requiring hospitalization.

TABLE 24-2 APPROACHES TO ASSESSMENT OF FUNCTION IN ELDERLY INDIVIDUALS

ASPECT BEING ASSESSED	*PREVISIT QUESTIONNAIRE*		*OFFICE STAFF ADMINISTERED*	
	LENGTH OF SCREEN*	INSTRUMENTS	LENGTH OF SCREEN*	INSTRUMENTS
Functional status	D	Activities of daily living Instrumental activities of daily living		
Advance directives	B	Specific question about advance directives		
MEDICAL ASSESSMENT				
Visual impairment	B	Single-item question	B	Snellen eye chart (see Table 423-1)
Hearing impairment	B	Hearing Handicap Inventory for the Elderly	B (if needed)	Whisper test Audioscope
Cognitive problems	B		D	Mini-cog (see Chapter 27)
Mind, affective problems	D	PHQ	B	
Falls, mobility, balance	B	Simple questions	B	Timed up-and-go test
Medication review	D			Inspection of medication bottles
Malnutrition	D	Single question	B	Weight
Urinary incontinence	B	Single question	B	International Consultation on Incontinence Modular Questionnaire short form if single question is positive (see Chapter 26)
Preventive services	D	Specific questions		
OTHER DIMENSIONS				
Environment	D	Home safety checklist		
Social support	B	Single question		
Financial status			B	Insurance status

*B = brief screen (e.g., <2 minutes); D = detailed evaluation (usually ≥5 minutes); PHQ = Patient Health Questionnaire (see text).

REVIEW QUESTIONS

1. A Physician Orders for Life-Sustaining Treatment (POLST) form orders must be respected in which of the following settings?

A. Hospital
B. Emergency department
C. Skilled nursing facility
D. Home (by emergency medical technicians)
E. All of the above settings

Answer: E Physician Orders for Life-Sustaining Treatment forms must be respected in all settings of care.

2. For frail older persons, the most important determining factor of whether a specific preventive service (e.g., mammography, colonoscopy, bone mineral density assessment, cholesterol lowering for primary prevention of heart disease) should be provided is which of the following?

A. Life expectancy
B. U.S. Preventive Services Task Force recommendations
C. Professional society (e.g., American College of Physicians) guidelines
D. Pay-for-performance incentives

Answer: A If a patient is unlikely to live long enough to accrue the benefits of treatment, the preventive service is not indicated. Some guidelines issued by professional societies do not consider comorbidity or life expectancy. Pay-for-performance initiatives do not consider age. The U.S. Preventive Services considers life expectancy only based on current age and only for some recommendations.

3. Which of the following statements about functional status is incorrect?

A. It is always impaired in dementia.
B. Impairment of instrumental activities (e.g., shopping, managing finances, performing housework) is more common than impairment of basic activities (e.g., bathing, dressing, transferring).
C. It can be assessed by self-report or direct observation.
D. It is has prognostic value in outpatient but not inpatient settings.

Answer: D Functional status has prognostic value in both outpatient and hospital settings. Functional impairment is required for the diagnosis of dementia and is used to differentiate dementia from mild cognitive impairment. Functional status can be assessed by self-report or objectively (e.g., by a physical or occupational therapist or with structured, performance-based instruments).

25

COMMON CLINICAL SEQUELAE OF AGING

JEREMY D. WALSTON

EPIDEMIOLOGY

Older adults make up the majority of patients actively treated in the health care system, in large part owing to their increased burden of chronic diseases but also because of their marked vulnerability to adverse health outcomes, such as functional and cognitive decline, falls, delirium (Chapter 28), and frailty. This age-related vulnerability is thought to have its basis in altered biology that results in tissue and physiologic system changes, which in turn may contribute to many of these conditions and to the chronic disease states commonly seen in older adults. Importantly, these biologic changes are likely to be heterogeneous and to occur at different chronologic ages and in different organs at different rates (Fig. 25-1). These complex age-related biologic changes represent a source of vulnerability that sets the stage for the marked increase in clinical sequelae observed in older adults.

PATHOBIOLOGY

Age-Related Cellular and Molecular Changes

The multiple biologic changes of aging affect important homeostatic functions and can lead to altered cellular function, declines in tissue resiliency, and cellular dropout. Several pathways become dysregulated with increasing age. First, autophagy, an intracellular process responsible for the recycling of damaged or redundant organelles or proteins, becomes less effective with age.[1] The result is an intracellular accumulation of dysfunctional mitochondria and proteins, which in turn can trigger cellular dysregulation through increased levels of free radicals, lower mitochondrial energy production, and programmed cell death or apoptosis. Second, senescent cell populations arise with increasing age and may lead to alterations in tissue and immune system function. For example, fibroblasts and fat cells evolve toward a phenotype whereby reproduction and cell death are less likely to take place, and survival persists in an altered, less functional state.[2] These senescent cells no longer function normally and often chronically secrete inflammatory cytokines and other bioactive molecules that alter surrounding tissues. Senescent T-cell populations also evolve with increasing age, perhaps related to early life viral infections. Although they are often normal in appearance and number, these T cells are less able to respond appropriately to immunogenic signals, thereby increasing vulnerability to infections. Third, some tissues become more sensitive to apoptosis, or programmed cell death. Although apoptosis is a normal cellular program that kills and disassembles damaged or redundant cells in all tissues, it accelerates with age and likely contributes to the vulnerability to chronic disease states, such as Parkinson disease, heart failure, and the generalized loss of cell number in many tissues. Fourth, evidence suggests that increased activity in transforming growth factor-β signaling may play an important role in the fibrotic changes that are observed in the heart, skeletal muscle, and lung tissue and that result in functional decrements with increasing age. Importantly, these aging-related molecular and cellular changes are heterogeneous and may affect individuals at different ages and in different tissues. However, the end result is increased susceptibility to chronic disease states, frailty, declines in function and cognition, and ultimately mortality.

Physiologic System Dysregulation and Its Consequences

Dysfunction in multiple physiologic stress response systems also plays a role in late-life vulnerability. Chronic diseases such as diabetes, vascular disease, chronic obstructive pulmonary disease, depression, and heart failure activate the innate immune system, the sympathetic nervous system, and the

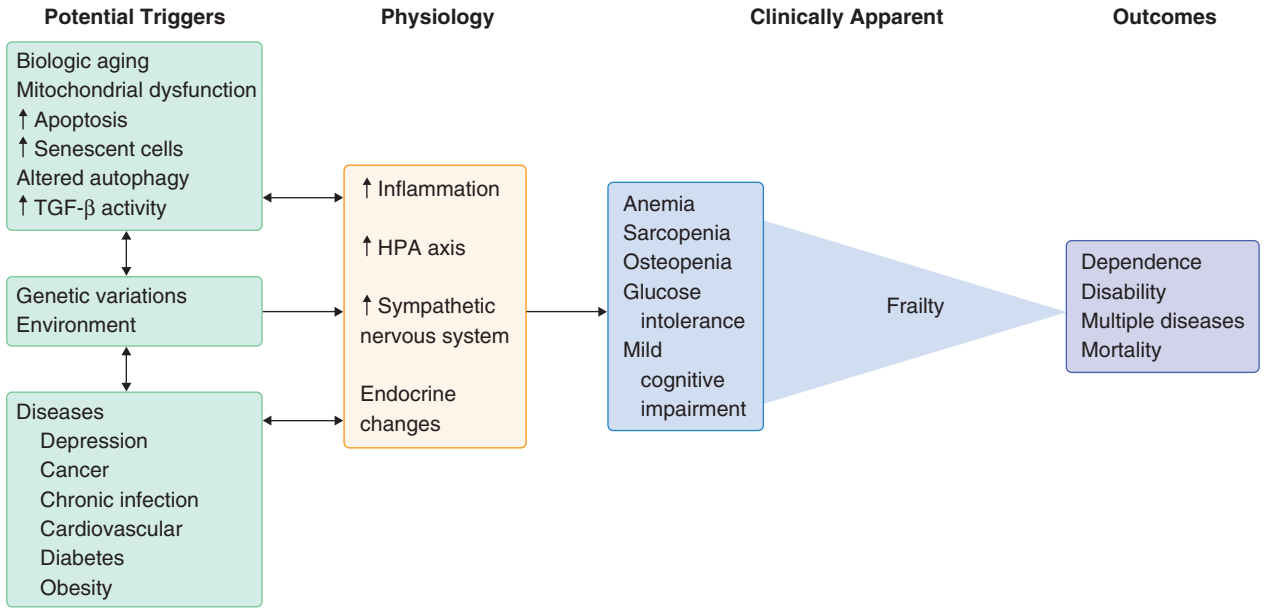

FIGURE 25-1. Comprehensive model pathway for biologic vulnerability to adverse outcomes in aging. HPA = hypothalamic-pituitary-adrenal; TGF-β = transforming growth factor-β.

hypothalamic-pituitary-adrenal axis, which in turn increase cortisol and the inflammatory cytokine interleukin-6 (IL-6).[3] These responses further exacerbate aging-related clinical conditions, such as osteoporosis and hypertension, and increase vulnerability to frailty, functional decline, accidental injury, and worsening chronic disease states[4] (E-Fig. 25-1).

CLINICAL MANIFESTATIONS

Some clinical manifestations are related not to physiologic aging but rather to cumulative exposures, such as with sun-related skin cancer (Chapter 203), or the delayed expression of genetic abnormalities, such as Huntington disease (Chapter 410) or polycystic kidney disease (Chapter 127). However, many organs and systems become less functional with age. For example, a healthy 70-year-old will have only about 50% of the lung function (Chapter 83) and renal function (Chapter 115) of a young adult. The resultant lack of physiologic reserve capacity does not affect day-to-day function but can greatly affect the ability to recover from a severe illness that exhausts the body's reserve capacity.

Despite normal baseline temperatures, older adults are more susceptible to hypothermia or hyperthermia (Chapter 109) after environmental exposure, even though they are less likely to develop fever with infections. For example, patients with pneumonia (Chapter 97) may present with confusion and dehydration rather than with fever and cough.

EFFECTS OF AGING ON SPECIFIC ORGANS AND SYSTEMS

Cardiovascular System

Between the ages of 20 and 80 years, left ventricular systolic function does not change, but the left ventricle gradually thickens. The result is that left ventricular filling in early diastole declines by 50%, and ventricular filling becomes more dependent on atrial contraction (Chapter 53). Although atherosclerosis is the most important cause of symptomatic cardiac disease in elderly people, the age-associated vascular stiffness results in an age-related increase in heart failure despite normal systolic function (Chapter 58). With the gradual loss of up to 90% of sinus node pacemaker cells by the age of 80 years, both the resting heart rate and the maximal heart rate with exercise decline. Conduction system dysfunction contributes to an increase in the prevalence of atrial fibrillation, which is seen in about 4% of community-dwelling older individuals (Chapter 64) and can develop in up to one third of the elderly after surgery (Chapter 433). Heart valves thicken and stiffen, and the prevalence of aortic stenosis and mitral annular calcifications rises (Chapter 75), often causing heart murmurs. Stiffening of the aorta causes an increase in systolic blood pressure, whereas diastolic blood pressure often stays stable or even declines (Chapter 67).

The combination of impaired ventricular filling and the inability to increase the heart rate with stress contributes to the postural hypotension that is seen in 20% of older individuals (Chapter 62) as well as their predisposition to syncope with stresses that younger individuals would tolerate. The reduced ability of the elderly to tolerate cardiovascular stress must be recognized and anticipated whenever they experience a major illness. In addition, coronary artery disease can limit cardiac reserve and increase the risk that hypotension will cause a secondary myocardial infarction.

Respiratory System

The chest wall stiffens with advancing age, and the lungs lose elastic recoil (Chapter 85). Maximal vital capacity declines by about 40%, but oxygen exchange declines by about 50% because of the additive effect of progressive ventilation-perfusion mismatching (Chapter 85). As a result, the arterial Po_2 of many 80-year-olds is about 70 to 75 mm Hg. The clinical manifestations are often progressive shortness of breath with exercise (Chapter 83) and an increased susceptibility to community-acquired pneumonia (Chapter 97) and even to aspiration pneumonia.

Gastrointestinal System

Taste and smell (Chapter 427) decline with advancing age. Food tends to taste less sweet and more bitter.

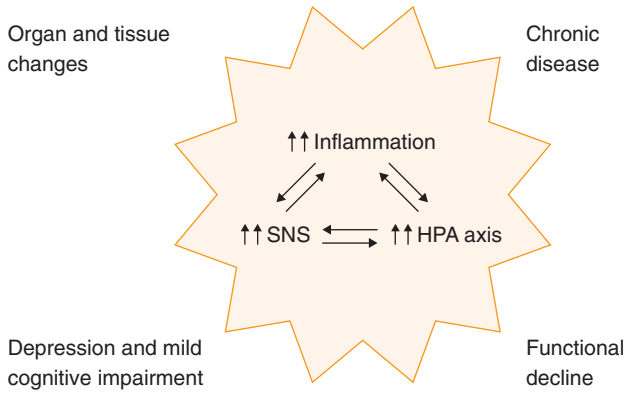
The esophageal sphincter can become lax (Chapter 138), thereby increasing reflux and even aspiration. Atrophic gastritis reduces the risk of duodenal ulcer but also the absorption of iron (Chapter 159) and vitamin B_{12} (Chapter 164). Delayed gastric emptying can lead to a sense of early satiety and decreased appetite.

A gradual decline in the number of hepatocytes decreases the weight of the liver by about one third by the age of 90 years and decreases the liver's ability to metabolize drugs (Chapter 29). Distal colonic motility from the rectosigmoid to the anal canal declines, and more than 60% of elderly individuals develop constipation (Chapter 136). Diverticula (Chapter 142) become more common with age and are seen in up to 50% of people older than age 80 years.

Urinary System

Glomerular filtration declines by about 1% per year, and kidney size declines by about one third in older adults (Chapter 115). Maximal concentrating capacity declines, and it becomes more difficult to excrete a salt load or to conserve water in the face of dehydration.

The bladder becomes more irritable with advancing age and may generate less power, which is especially a problem in men with prostatic hypertrophy (Chapter 129). By comparison, urinary incontinence (Chapter 26) is more prevalent in women. Residual bladder urine volume increases and nocturia



E-FIGURE 25-1. **Dysregulation of stress response systems and their influence on vulnerability to adverse outcomes. HPA = hypothalamic-pituitary-adrenal; SNS = sympathetic nervous system.**

is common. Vaginal and urethral atrophy predispose women to urinary tract infections (Chapter 284).[5]

The kidney is more susceptible to the effects of medications, particularly nonsteroidal anti-inflammatory drugs, which can result in sodium and fluid retention and subsequent hypertension. In elderly individuals, a slight acidemia results from impaired acid excretion and may contribute to the development of osteoporosis.

Endocrine System

Growth hormone levels fall with advancing age (Chapter 224), thereby resulting in decreased muscle strength, thinning of bones and skin, and increased central fat. However, growth hormone replacement does not appear to result in improved muscle strength. Levels of thyroid hormones do not decline with age (Chapter 226). Parathyroid hormone levels, however, commonly increase, especially in women, probably in response to the kidney's declining ability to maintain normal serum levels of phosphorus and calcium (Chapters 199 and 245).

The ability of the pancreas to release insulin is blunted with advancing age (Chapter 229), but the kidney's clearance of insulin also decreases. The net result is maintained plasma insulin levels in the fasting state but an increased likelihood of postprandial or stress-induced hyperglycemia. Dramatic declines in estrogen and progesterone production precipitate menopause at an average age of 51 years (Chapter 240). Testosterone levels begin to decrease in men by about 50 years of age, often with resulting declines in sexual function but not in the potency of semen (Chapter 234). Testosterone supplements reverse the muscle loss and sexual implications of declining testosterone levels but increase the risk of cardiovascular complications five-fold.

Immune System

Declines in the responsiveness of the immune system explain why the incidence of autoimmune conditions, such as systemic lupus erythematosus (Chapter 266) and multiple sclerosis (Chapter 411), declines in the elderly. However, this same decline explains increased morbidity and mortality with infectious diseases and the increased risk of reactivating infections such as tuberculosis (Chapter 324) and herpes zoster (Chapter 375). These risks emphasize the importance of vaccination against herpes zoster, influenza, pneumococcal pneumonia, and tetanus in the elderly (Chapter 18).

Hematopoietic System

Hematopoiesis (Chapter 156) is generally sustained with aging, except in response to marked stress. The one exception is that the hematocrit declines somewhat in elderly men, presumably owing to their lower testosterone levels.

Integumentary System

With aging, the epidermis and dermis adhere less tightly and the subcutaneous tissue thins, thereby making the skin feel looser and more likely to wrinkle and ulcerate. Clinical sequelae include senile purpura (Fig. 25-2) due to tears in small venules after bumps or abrasions (Chapter 440). Ultraviolet light exposure also predisposes to skin cancer (Chapter 203), rosacea (Chapter 439), xerosis, and hair loss (Chapter 442).

Wound healing is also compromised, and complete skin healing can take 5.5 weeks instead of 3.5 weeks in individuals older than 65 years. As a result, older adults are more prone to pressure sores when they are bedridden. Pressure sores, which are necrotic areas of muscle, subcutaneous fat, and skin, usually occur between underlying bone and a hard surface (or a soft surface during a prolonged time) as a result of compression and subsequent ischemia (Fig. 25-3). A continuous-pressure threshold of only 30 to 35 mm Hg is needed to cause pressure sores, and a standard mattress can generate pressures five times as high. In addition to pressure injury, other contributing factors include shear injury from rubbing constantly against underlying surfaces; burning injury from friction of the superficial skin layers; and moisture that softens the skin, makes it stick to underlying surfaces, and provides easy access for infection.

Safe positioning, regular turning, avoidance of direct pressure, pressure-reducing beds, deep foam mattresses, and air suspension beds can reduce the incidence of pressure sores. Pressure sores should be photographed to establish a baseline. The wound should be freed of any pressure to prevent additional pressure ulcers. Wet-to-dry dressings are a mainstay, and semiocclusive and occlusive dressings also can be helpful. Surgical or chemical débridement is often required. Topical or systemic antibiotics (Chapter 282) may be needed. Pressure ulcers usually heal within 6 months, but surgical repair is sometimes required.

FIGURE 25-2. Senile purpura is a common and benign condition that results from impaired collagen production and capillary fragility in some older adults. In the absence of other signs of disease, no investigation is necessary. (From Forbes CD, Jackson WF. Color Atlas and Text of Clinical Medicine. 3rd ed. London: Mosby; 2003.)

FIGURE 25-3. Severe sacral pressure sore, one of the serious but preventable complications of immobility. (From Forbes CD, Jackson WF. Color Atlas and Text of Clinical Medicine. 3rd ed. London: Mosby; 2003.)

Musculoskeletal System

Bone mass and density decrease by about 1% per year but by up to 2 to 3% per year in the first 5 to 10 years after menopause in women (Chapters 243 and 240). Tendons and ligaments become less elastic, thereby contributing to a higher incidence of rupture, especially of the Achilles tendon. Muscle mass declines by about 25% by the age of 70 years and by 30 to 40% by the age of 80 years unless it is offset by exercise.

Clinical Pharmacology

Older adults take a disproportionate share of all prescription (Chapter 29) and nonprescription medications (Chapter 39), and they are at increased risk of drug-drug interactions. Because the elderly have less muscle mass and more fat as a proportion of total body weight, they are more sensitive to the effects of water-soluble drugs and have prolonged effects from lipophilic drugs. Declines in renal and hepatic function reduce the clearance of most drugs, although drugs that are conjugated and glucuronidated are cleared relatively normally. Elderly people also are more likely to be nonadherent to prescribed regimens owing to the number of medications and their cost, mental impairment, and medication side effects.

Cancer and Cancer Screening

The incidence of most cancers rises with age, although many cancers may be less aggressive in the elderly than in younger persons. Some screening options, such as colonoscopy, are associated with their own intrinsic risks (Chapter 134), and all screening tests carry the potential side effects of false-positive results. All of these risks are greater in elderly persons, who also have fewer years of life to gain from early detection and treatment of cancer. As a result, screening recommendations should be adjusted in elderly persons. Examples include discontinuing colon cancer screening after the age of 75 years (Chapter 15), limiting screening mammography to women with at least a 10-year life expectancy,[6] advising any prostate cancer screening only to men

with a 15-year life expectancy (Chapter 15), and often discontinuing Pap smear testing in women older than 65 years if prior active screening results have been negative.

Sensory and Sleep

In addition to age-related cognitive decline (Chapters 27 and 28), hearing loss develops in about 25% of individuals older than 65 years (Chapter 428), with decreased neural transmission leading to difficulty in discriminating important sounds from background noise. Presbycusis diminishes the ability to hear high-frequency sounds.

The thickening and stiffening of the lens diminish the ability to focus on nearby objects and increase glare (Chapter 423). Transmission of light through the lens may decline by 50% or more, so elderly individuals require more ambient light. Vitreal detachment causes floaters that also can interfere with vision. Decreased tear production causes dryness of the eyes. All of these conditions contribute to a decline in visual acuity to the extent that 40% of men and 60% of women older than 65 years have a visual acuity of 20/70 or worse.

Older adults tend to have difficulty in sleeping (Chapter 405) yet spend much more time in bed. Sleep apnea also becomes more common with advancing age (Chapter 100).

Frailty as a Clinical Marker of Vulnerability in Older Adults

Frailty, which is a late-life syndrome of weakness, slowness, and weight loss, is associated with high risk of adverse health outcomes and mortality. For example, diminished heart rate variability, which is a marker of dysregulated sympathetic nervous system activity, is associated with aging, frailty, and cardiac arrhythmias. Frail older adults have significantly higher levels of salivary cortisol during the afternoon nadir period, thereby suggesting chronically increased activity of the hypothalamic-pituitary-adrenal axis. Elevated levels of inflammatory cytokines, especially IL-6, tumor necrosis factor-α receptor 1 (TNFR1), and C-reactive protein, are strongly related to functional decline, frailty, chronic disease, and mortality in older adults,[7] probably owing to increased fat, more senescent cells, and free radical production from altered mitochondria. IL-6 is likely to have a negative impact on stem cells and satellite cells, which in turn may contribute to the chronic anemia and age-related declines in skeletal muscle (sarcopenia) and bone mass (osteopenia) commonly observed in frail, older adults. TNFR1 stimulates apoptosis and necroptosis, which are cell programs that lead to cell death and possibly tissue depletion and vulnerability later in life.

In addition to stress response systems, endocrine factors that normally maintain muscle mass also play a role in frailty. For example, the adrenal androgen dehydroepiandrosterone sulfate and insulin-like growth factor 1 are significantly lower in frail adults.

Frailty serves as a clinical indicator of which older adults are at high risk for adverse outcomes, including delirium (Chapter 28), falls, and mortality. Frailty is characterized by signs and symptoms of increasing weakness, fatigue, and declines in activity. Validated frailty screening tools (Table 25-1) enable physicians to identify patients at highest risk of adverse outcomes and mortality and to develop preventive interventions that will decrease risk and improve quality of life.

One approach is to measure physiologic parameters such as grip strength, walking speed, and weight loss as well as to gather information about activity and fatigue levels. With use of this approach, the prevalence of frailty rises with increasing age; approximately 10% of community-dwelling adults older than 65 years meet these frailty criteria and subsequently are at increased risk of functional decline, falling, hospitalization, and death, even after adjustment for age, socioeconomic and smoking status, and multiple common disease states.[8] The Fried or the Cardiovascular Health Study approach has been widely used to identify elders for whom interventions may be helpful.

Frailty increases the likelihood for development of influenza or influenza-like illness in the 6 months after vaccination; the likelihood of requiring care in a skilled nursing or long-term care facility after hospitalization for general surgery; poor renal transplant graft function and early hospital readmission after transplantation; falls, hospitalization, and mortality in patients on hemodialysis for chronic renal failure; and the risk of death in aging intravenous drug users. Biologic differences between frail and non-frail older adults (see Fig. 25-1) drive the marked vulnerability to adverse outcomes observed in the frail subjects.[9] Interventions should be targeted to the specific characteristics of a patient's frailty. Increasing physical exercise is the mainstay of most programs.

TABLE 25-1 FOUR COMMONLY USED INSTRUMENTS TO MEASURE FRAILTY IN OLDER ADULTS, WITH RELEVANT MEASUREMENT DOMAINS AND SCORING CRITERIA

INSTRUMENT	DOMAINS	SCORING
Fried frailty phenotype (biologic syndrome model)*	Physical function (slowness, low activity, weakness), nutritive (weight loss), and exhaustion	Score range: 0 to 5 Frail = ≥3 criteria present Intermediate/pre-frail = 1-2 criteria present Robust = 0 criteria present
Frailty index/ accumulation of deficits (burden model)†	Diseases, ability in ADL, health attitudes/values, and symptoms/signs from the clinical and neurologic examinations	Number of deficits present and divided by the number of deficits taken into consideration Higher proportion equates to a higher level of frailty
Vulnerable Elders Survey (VES-13)‡	Physical function and ADL/IADL disability	Score range: 0 to 10 Frail = score ≥3
1994 Frailty measure (functional domains model)§	Physical function, nutritive function, cognitive function, sensory problems	Subject scoring a 3 or higher on at least one item in any domain is considered to have a problem or difficulty in that domain Frail = problems/difficulties in ≥2 domains

Details on the use and implementation of these tools can be found in the referenced articles.
ADL = activities of daily living; IADL = instrumental activities of daily living.

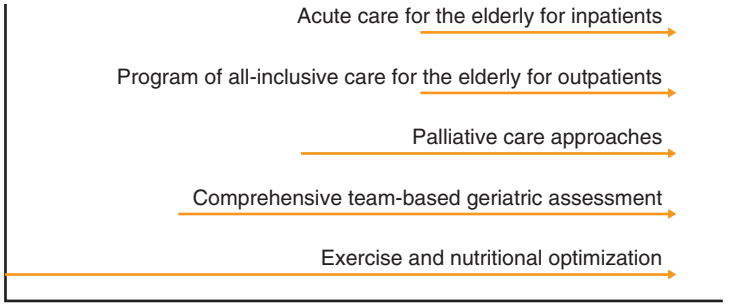

FIGURE 25-4. Assessment and treatments in frail and vulnerable older adults.

The Care of Frail Older Patients in Clinical Settings

Focused prevention of iatrogenic injuries or recurrent hospitalizations and remediation of symptoms are often warranted for frail vulnerable older adults[10] (Fig. 25-4). Physical activity, exercise interventions, and nutritional supplementation can reduce disability and symptoms and improve quality of life across the spectrum of robust to frail older adults. In addition, exercise and weight loss together improve function in obese and frail older adults. Other options include a team-based approach that engages the patient, family members, caregivers, health care providers, and social workers. Classic palliative care, with appropriate pain management, less invasive treatment plans, limited hospital visits, and organized home care plans, can greatly improve quality of life. If the patient has frequently been admitted to an inpatient setting, a program for all-inclusive care or a medical daycare setting may help prevent recurrent admissions and improve quality of life. Once admitted to the hospital, frail older adults may benefit from being congregated in a unit that specializes in their care and can provide attention to their functionality, continence, sleep disturbances, delirium, and palliative care issues.

TABLE 25-2 EVALUATION OF A PATIENT WHO HAS FALLEN

Blood tests to exclude anemia, infection, and metabolic problems such as diabetes and thyroid disease
Electrocardiography to evaluate heart disease
24-Hour electrocardiographic recording or loop monitoring to evaluate arrhythmias (Chapter 62)
Echocardiography for patients with significant heart murmurs (Chapter 55)
Drug levels to determine whether a patient is being undertreated or overtreated with a particular drug
If focal neurologic signs or symptoms are present, a computed tomography scan of the brain
If suggestive symptoms are present, radiography of the neck or spine to look for spinal stenosis

Falls

Falls are a common manifestation of frailty. Contributing factors include cardiopulmonary disease, poor eyesight, hearing loss, balance disturbances, weakness, movement disorders, neuropathies, poor judgment, depression, osteoporosis, arthritis, and foot disorders. The risk of falling also increases in patients who take more prescription medications, especially hypnotics, muscle relaxants, antihypertensive agents, diuretics, and antidepressant medications. Environmental risks include stairs, loose objects, rugs, poor lighting, poorly fitting shoes, uneven pavements, and slippery surfaces.

The approach to a patient who has fallen must include a careful history of the circumstances surrounding the fall and all conditions that could contribute to it. The physical examination should test vision, gait, balance, muscle strength, neurologic function, and pulmonary function. Further testing is recommended whenever the history and physical examination do not reveal the cause of falling or if they reveal conditions that require further evaluation (Table 25-2). In general, this evaluation is similar to the evaluation for syncope (Chapter 62).

Given the strong relationship between vitamin D deficiency and frailty,[11] clinical trials are under way with some evidence that vitamin D_3 supplementation may reduce the mortality in elderly individuals.[A6] Exercise programs, including Tai Chi, improve strength and balance as well as help prevent falls that are often associated with frailty.[A4,A8] Hip protectors to reduce fractures in nursing home patients and in ambulatory older individuals have shown mixed results, and compliance with these cumbersome devices is only 25 to 70%. Further studies of types and doses of exercise may help elucidate optimal regimens for preventing frailty and for optimizing health and well-being of frail, older adults.

REVIEW QUESTIONS

1. A 74-year-old man who is in robust health and who exercises frequently asks what supplements will keep him strong and fit. Which of the options has been proved effective in maintaining quality of life and fitness in older adults?

A. Growth hormone
B. Testosterone
C. Vitamin D and calcium
D. Regular exercise
E. Coenzyme Q

Answer: D Many studies have evaluated the safety and efficacy of hormones and other treatments for maintenance of strength and function in older age groups. Although growth hormone, testosterone, and vitamin D may be helpful in those with diagnosed deficiencies, there is no evidence that giving these agents to a relatively healthy person without signs or symptoms of such deficits would be beneficial. Regular exercise is the only listed intervention that has been shown to be safe and efficacious for building strength and enhancing quality of life in almost any setting.

2. An 82-year-old patient presents with a chief complaint of "I just don't have any energy." He notes muscle wasting, fatigue, and functional decline during the past year. Extensive medical evaluation in the next month reveals no obvious medical conditions that explain this decline. What should you recommend?

A. Careful medical monitoring
B. Assessment of his risk for falling
C. Exercise and activity regimen
D. Social engagement
E. All of the above

Answer: E This obviously frail patient is at high risk for adverse outcomes, social isolation, and mortality in the coming years. He warrants careful medical monitoring, assessment of the risk for falling, and increasing social engagement. In addition, exercise has been demonstrated to be helpful in even the frailest older adults. Hence, all of the answers are appropriate in this patient.

26

INCONTINENCE

NEIL M. RESNICK

DEFINITION

Urinary incontinence is the involuntary leakage of urine sufficient to be a health or social problem.

EPIDEMIOLOGY

More than twice as common in women as in men, the prevalence of incontinence increases with age. Incontinence afflicts 15 to 30% of older adults living at home, one third of those in acute care settings, and half of those in nursing homes. It predisposes to perineal rashes, pressure ulcers, urinary tract infections, urosepsis, falls, and fractures, and it is associated with embarrassment, stigmatization, isolation, depression, anxiety, sexual dysfunction, and risk for institutionalization. Its cost in the United States exceeds $26 billion annually.

Despite these considerations, geriatric incontinence remains largely neglected, by patients and physicians alike. This is unfortunate because its increased prevalence with age relates more to age-associated diseases and functional impairments than to age itself. Most important, incontinence is usually treatable and often curable at all ages, even in frail elderly people, although the approach in older patients must be broader than that employed in younger patients.

PATHOBIOLOGY

At any age, continence depends not only on the integrity of lower urinary tract function but also on the presence of adequate mentation, mobility, motivation, and manual dexterity. Although incontinence in younger patients is rarely associated with deficits in these domains, such deficits occur commonly in older patients, in whom they can cause or exacerbate incontinence or influence therapeutic approaches.

With age, bladder capacity does not change, but bladder sensation and contractility decrease. At the cellular level, detrusor smooth muscle develops a "dense band pattern" characterized by dense sarcolemmal bands with depleted caveolae. This depletion may mediate the age-related decline in bladder contractility. In addition, an incomplete disjunction pattern characterized by scattered protrusion junctions develops and may underlie the high prevalence of involuntary bladder contractions (detrusor overactivity) in older adults of both sexes. Bladder ischemia and/or inflammation may also contribute.[1,2] Urethral length and sphincter strength decrease in women, whereas the prostate enlarges in most men and causes measurable obstruction in about half. The postvoid residual volume in the bladder also increases in both sexes but normally to less than 100 mL. In addition, elderly people often excrete most of their fluid intake at night, even in the absence of venous insufficiency, renal disease, heart failure, or prostatism. Because this shift in nocturnal fluid excretion is coupled with an age-associated increase in sleep disorders, most older adults have one or two episodes of nocturia per night.

None of these changes causes incontinence, but all predispose to it. This predisposition, combined with the increased likelihood that an older person will encounter an additional pathologic, physiologic, or pharmacologic insult, explains the increased prevalence of incontinence with age. Thus, the onset or exacerbation of incontinence in an older person is likely to be due to precipitants that are outside the lower urinary tract and that are amenable to medical intervention. Furthermore, treatment of the precipitants alone may be sufficient to restore continence, even if there is coexisting urinary tract dysfunction. For example, a flare of hip arthritis in a woman with age-related detrusor overactivity may decrease mobility sufficiently to convert her urinary urgency into incontinence. Treatment of the arthritis, rather than the involuntary detrusor contractions, will not only restore continence but also lessen pain and improve mobility. Because of their frequency, reversibility, and association with morbidity beyond incontinence, the transient precipitant causes should be addressed first.

Causes of Transient Incontinence

Incontinence is transient in up to one third of community-dwelling elderly people and in up to half of acutely hospitalized patients. Although most

TABLE 26-1 CAUSES OF TRANSIENT INCONTINENCE: DIAPERS MNEMONIC

Delirium	Result of underlying illness or medication; incontinence is secondary and abates once the cause of delirium is corrected	
Infection—*symptomatic* UTI	Acute, symptomatic UTI causes incontinence, but the far more common asymptomatic bacteriuria does not	
Atrophic urethritis/vaginitis	Characterized by vaginal erosions, telangiectasia, petechiae, and friability; may cause or contribute to incontinence. Although oral estrogen may worsen incontinence, a 3- to 12-month course of topical estrogen can be useful	
Pharmaceuticals	*Drug type:*	*Potential effects on continence:*
	Sedative-hypnotics (e.g., long-acting benzodiazepines; alcohol)	Sedation, delirium, decreased mobility
	Anticholinergics (dicyclomine, disopyramide, sedating antihistamines, antipsychotics, tricyclic antidepressants, anti-Parkinson, antidepressants) (*not* SSRIs)	Urinary retention, overflow incontinence, delirium, impaction; the antipsychotics also decrease mobility
	Opiates	Urinary retention, stool impaction, sedation, delirium
	α-Adrenergic antagonists	Relax sphincter; may induce stress incontinence in women
	α-Adrenergic agonists	Urinary retention in men (tighten sphincter, prostate)
	Calcium-channel blockers, especially the dihydropyridines	Urinary retention; nocturnal diuresis due to fluid retention
	"Loop" diuretics (thiazide-like agents only rarely cause it)	Polyuria, frequency, urgency
	NSAIDs	Nocturnal diuresis due to fluid retention
	Thiazolidinediones	Nocturnal diuresis due to fluid retention
	Some nociceptives (gabapentin, pregabalin)	Nocturnal diuresis due to fluid retention; sedation; delirium
	Dopamine receptor agonists (e.g., ropinirole, pramipexole)	Nocturnal diuresis due to fluid retention
	Angiotensin-converting enzyme inhibitors	Drug-induced cough leads to stress incontinence in women
	Vincristine	Urinary retention due to neuropathy
Excess urine output	From large intake, diuretic agents (theophylline, caffeinated beverages, alcohol), and metabolic disorders (hyperglycemia, hypercalcemia); nocturnal incontinence may result from mobilization of peripheral edema (heart failure, venous insufficiency, side effects of medications)	
Restricted mobility	Often results from overlooked, correctable conditions such as arthritis, pain, foot problems, postprandial hypotension, or fear of falling	
Stool impaction	May cause both fecal and urinary incontinence that remit with disimpaction	

NSAIDs = nonsteroidal anti-inflammatory drugs; SSRI = selective serotonin reuptake inhibitor; UTI = urinary tract infection.
Adapted from Resnick NM, Tadic SD, Yalla SV. Geriatric incontinence and voiding dysfunction. In: Wein AJ, Novick AC, Partin AW, et al, eds. *Campbell-Walsh Urology*, 10th ed. St. Louis: Elsevier; 2010.

transient causes are outside the lower urinary tract (Table 26-1), three points warrant emphasis. First, the risk for transient incontinence is increased if, in addition to physiologic changes of the lower urinary tract, there also are pathologic changes. Anticholinergic agents are more likely to cause overflow incontinence in individuals with a weak or obstructed bladder, whereas excess urine output is more likely to cause urge incontinence in people with detrusor overactivity or impaired mobility. Second, these transient causes may persist if left untreated and should not be dismissed merely because incontinence is long-standing. Third, identification of the most common cause is of little value because causes vary among individuals, and geriatric incontinence is rarely due to just one cause.

Causes of Established Incontinence Related to the Lower Urinary Tract

Detrusor overactivity, also called involuntary bladder contraction or *overactive bladder*, generally causes *urge incontinence* and is the most common type of lower urinary tract dysfunction in incontinent elderly people, in whom it accounts for about two thirds of cases. Histologically, detrusor overactivity is associated with the complete disjunction pattern, with widening of the intercellular space, reduction of normal (intermediate) muscle cell junctions, and emergence of novel protrusion junctions and ultraclose abutments that connect cells together in chains. These connections may mediate a change in cell coupling from a mechanical to an electrical mechanism that results in involuntary bladder contraction. Other potential causes include ischemia, abnormalities in suburothelial myofibroblasts, and changes in central nervous system structural and functional control mechanisms.

At any age, detrusor overactivity is usually idiopathic, but it can be associated with a variety of other causes that may affect prognosis and management. Such conditions include an upper motor neuron lesion (Chapters 400 and 419), urethral obstruction, stress incontinence, bladder calculus, and bladder carcinoma (Chapter 197).

Detrusor overactivity exists as two subsets in elderly people: one in which contractile function is preserved and one in which it is impaired. The latter condition, termed *detrusor hyperactivity with impaired contractility*, has several implications. First, because the bladder is weak, these patients commonly develop urinary retention, which is also seen in patients with outlet obstruction and detrusor underactivity. Second, even in the absence of retention, detrusor hyperactivity with impaired contractility mimics other lower urinary tract causes of incontinence. For instance, if the involuntary detrusor contraction occurs coincident with a stress maneuver and if the weak contraction is not detected, detrusor hyperactivity with impaired contractility will be misdiagnosed as stress incontinence. Alternatively, because detrusor hyperactivity with impaired contractility may be associated with urinary urgency, frequency, weak flow rate, elevated residual urine, and bladder trabeculation, in men it may mimic prostatic obstruction. Third, anticholinergic therapy of detrusor hyperactivity with impaired contractility may result in urinary retention owing to bladder weakness, thereby requiring alternative therapeutic approaches.

Stress incontinence, which is the second most common cause of incontinence in older women and the dominant cause in middle-aged women, usually reflects urethral hypermobility plus some degree of sphincter weakness. Stress incontinence is rare in men but can result from sphincter damage following radical but not transurethral prostatectomy.

Urethral obstruction is the second most common cause of established incontinence in older men, although most obstructed men are not incontinent. When obstruction is associated with incontinence, it usually presents as urge incontinence owing to the associated detrusor overactivity; overflow incontinence is uncommon. Outlet obstruction is rare in women but may result from a bladder neck suspension or from urethral kinking associated with a large cystocele.

Detrusor underactivity is usually idiopathic. When it causes incontinence, it is associated with overflow incontinence (<10% of incontinence).

Damage to lower urinary tract innervation can cause several types of dysfunction. A brain lesion may cause detrusor overactivity. A spinal cord lesion (Chapters 189 and 400) above the sacral level can cause both detrusor overactivity and detrusor-sphincter dyssynergia, a condition in which the sphincter contracts rather than relaxes during detrusor contraction; the result can be severe outlet obstruction and hydronephrosis. A spinal cord lesion below the sacral level can cause detrusor underactivity, sphincter weakness, or both. Peripheral and autonomic nerve damage can cause still additional problems. Because *neurogenic bladder* is such a nonspecific term, it is preferable to refer to the specific dysfunction that it causes.

Causes of Incontinence Unrelated to the Lower Urinary Tract (Functional Incontinence)

"Functional" incontinence, which is often cited as a distinct type of geriatric incontinence and attributed to deficits of cognition and mobility, implies that urinary tract function is normal. However, normal urinary tract function is the exception, even in continent elderly people, and is rarely observed in incontinent elderly people. Moreover, incontinence is not inevitable, even with dementia or immobility. Among the most severely demented

institutionalized residents, nearly 20% are continent; among those who can transfer from a bed to a chair, nearly half are continent. Functionally impaired individuals also are the most likely to suffer from factors that cause transient incontinence, and a diagnosis of functional incontinence may result in failure to detect these reversible causes. Finally, if functionally impaired individuals also have urethral obstruction or stress incontinence, they may benefit from targeted therapy. Nonetheless, functional impairment often contributes to incontinence, and addressing its causes and those of transient incontinence may ameliorate incontinence sufficiently to obviate the need for further investigation.

CLINICAL MANIFESTATIONS

The manifestations of transient incontinence depend on the underlying condition. For established incontinence, detrusor overactivity usually manifests as *urge incontinence,* characterized by leakage that follows the *abrupt* onset or intensification of a desire to void, leakage of a moderate to large amount, urinary frequency (>8 voids/day), nocturia, and nocturnal incontinence. However, some patients with detrusor overactivity may present without the urge component. *Stress incontinence* causes leakage that coincides *instantaneously* with both the onset and cessation of a cough or other cause of increased abdominal pressure; nocturnal leakage is rare. Some patients report both types of incontinence, or *mixed incontinence*, but it is useful to determine which component is the most bothersome. In men with sphincter damage following radical prostatectomy, leakage resembles the intermittent drip of a leaky faucet. Occasionally, patients present with incontinence that is more difficult to characterize clinically without further testing.

DIAGNOSIS

In addition to a targeted clinical evaluation (Table 26-2), a bladder diary can provide diagnostic clues and guide therapy (Fig. 26-1). For example, incontinence occurring only between 8 AM and noon may be caused by a morning loop diuretic. Incontinence that occurs at night in a demented man with heart failure, but not during a 4-hour nap in his wheelchair, is likely due to nocturnal diuresis associated with his heart failure and not to dementia, impaired mobility, or prostatic obstruction. A woman with volume-dependent stress incontinence may leak only on the way to void after a full night's sleep, when

TABLE 26-2 CLINICAL EVALUATION OF THE INCONTINENT PATIENT

HISTORY
Type (urge, stress, overflow, or mixed)
Incontinence frequency, severity, duration
Pattern (diurnal, nocturnal, or both; also, e.g., after taking medications)
Associated symptoms (straining to void, incomplete emptying, dysuria, hematuria, suprapubic/perineal discomfort)
Alteration in bowel habit/sexual function (because of proximity to the bladder and shared innervation)
Other relevant factors (cancer, acute illness, neurologic disease, pelvic or lower urinary tract surgery/radiation therapy)
Medications, including nonprescription agents (see Table 26-1)
Brief assessment of cognitive and physical function
PHYSICAL EXAMINATION
Identify other relevant medical conditions (e.g., congestive heart failure, peripheral edema)
If stress incontinence suspected, determine whether leakage *coincides* with the onset *and* cessation of a single, forceful cough
Palpate for bladder distention after voiding
Pelvic examination to detect atrophic vaginitis, pelvic muscle laxity, pelvic mass
Rectal examination (skin irritation, resting tone and voluntary control of anal sphincter, prostate nodule; fecal impaction (*note:* prostate size correlates poorly with presence of urethral obstruction)
Neurologic examination (mental status and elemental examination, including sacral reflexes and perineal sensation)
INITIAL INVESTIGATION
Bladder diary (see Fig. 26-1)
Metabolic survey (electrolytes, calcium, glucose, and urea nitrogen as appropriate)
Measure postvoid residual volume, by portable ultrasound if available
Urinalysis to detect sterile hematuria or infection; culture if new-onset or worsening incontinence
Renal ultrasound to detect hydronephrosis in men whose postvoid residual volume urine exceeds about 200 mL
Urine cytology for patients with hematuria, pain, or unexplained new-onset or worsening incontinence
Uroflowmetry for men in whom urethral obstruction is suspected
Cystoscopy for patients with hematuria, suspicion of lower urinary tract pathology (e.g., bladder fistula, stone, or tumor; urethral diverticulum), or need for lower urinary tract surgery

FIGURE 26-1. Sample bladder diary. Bladder diary of an incontinent 75-year-old man. Urodynamic evaluation excluded urethral obstruction and confirmed a diagnosis of detrusor hyperactivity with impaired contractility (detrusor hyperactivity with impaired contractility). Note the 24-hour urine output of nearly 3 liters due to the belief that drinking 10 glasses of fluid per day was "good for my health." (He did not mention this until queried about the voiding record.) Given the typical voided volume of 150 to 250 mL and a measured postvoid residual of 150 mL, excess fluid intake was overwhelming his usual bladder capacity of 400 mL (150+250 mL). Although involuntary bladder contractions were present, the easily reversible volume component of the problem, combined with the risk for precipitating urinary retention with an anticholinergic agent, prompted treatment with volume restriction alone. After daily urinary output dropped to 1500 mL, frequency abated, and incontinence resolved. (Adapted from DuBeau CE, Resnick NM. Evaluation of the causes and severity of geriatric incontinence: a critical appraisal. *Urol Clin North Am*. 1991;18:243-256.)

her bladder contains more than 400 mL—more than it ever does during her continent waking hours.

Because urinary retention is difficult to detect by examination and can affect diagnosis and therapy, the postvoid residual volume should be determined routinely, except possibly in middle-aged women with a classic presentation of stress incontinence. For example, in a randomized trial of women with uncomplicated, demonstrable stress urinary incontinence and a postvoid residual volume of less than 150 mL, preoperative office evaluation alone provided similar 1-year outcomes as did evaluation with urodynamic testing.■ Urodynamic testing is generally recommended only when diagnostic certainty is required, such as before most surgical repairs in older patients, or if there is evidence of a serious underlying cause of the incontinence, such as a brain or spinal cord lesion, carcinoma of the bladder or prostate, hydronephrosis, or bladder calculus.[3] Urodynamic evaluation comprises a battery of tests designed to assess the lower urinary tract during the filling and voiding phases of micturition. The selection among tests depends on the clinical setting and question to be answered; for instance, measuring detrusor pressure and urine flow during voiding can determine whether urethral obstruction is present, whereas monitoring bladder and urethral pressures during the filling phase and with coughing may be helpful for patients with an atypical presentation of mixed incontinence.

TREATMENT

Optimal therapy requires a multifactorial approach (Table 26-3), including treatment of transient causes, underlying medical conditions, functional impairments, and the urinary tract abnormality itself. Although pads and diapers have a role, they remain an adjunct to more specific therapy.

Behavioral Therapy

Behavioral therapy includes education, self-monitoring with a bladder diary, adjustment of the intake of fluid and caffeine,[3,4] weight loss for overweight women with stress incontinence,■ use of aids (e.g., a bedside urinal), and various types of bladder retraining and urethral sphincter exercises (e.g., progressively increasing voiding intervals, strategies to cope with urgency, and pelvic muscle exercises).[4,5]■ The efficacy of behavioral therapy is equivalent to pharmacotherapy for urge incontinence. For stress incontinence, the efficacy of behavioral therapy is superior to drugs but inferior to surgery.[5]■■ Moreover, combining behavioral and pharmacologic therapy may prove more beneficial than either treatment alone, especially for urge incontinence,■■ because neither therapy generally abolishes involuntary bladder contractions.[6] For institutionalized patients who are cognitively impaired but can state their name and are partly mobile, regular daytime reminders to void ("prompted voiding")

TABLE 26-3 STEPWISE APPROACH TO TREATMENT OF URINARY INCONTINENCE*

CONDITION	CLINICAL TYPE OF INCONTINENCE†	TREATMENT
Detrusor overactivity with normal contractility	Urge	1. Bladder retraining or prompted voiding regimens 2. ± Bladder relaxant medication if needed and not contraindicated (see drug list below). If treatment fails, consider posterior tibial neurostimulation, sacral neuromodulation, or intradetrusor injection of onabotulinumtoxinA 3. Indwelling catheterization alone is often unhelpful because detrusor spasms often increase, leading to leakage around the catheter 4. In selected cases, induce urinary retention pharmacologically and add intermittent or indwelling catheterization‡
Detrusor hyperactivity with impaired contractility	Urge§	1. If bladder empties adequately, behavioral methods (as above) ± bladder relaxant medication (low doses; especially feasible if sphincter incompetence coexists) 2. If residual urine >150 mL, augmented voiding techniques¶ or intermittent catheterization (± bladder relaxant medication). If neither feasible, undergarment or indwelling catheter‡ 3. In selected cases, induce urinary retention pharmacologically and add intermittent or indwelling catheterization‡
Stress incontinence	Stress	1. Conservative methods (weight loss if obese; treatment of cough or atrophic vaginitis; physical maneuvers to prevent leakage [e.g., tighten pelvic muscles before cough, cross legs]; occasionally, use of tampon or pessary is helpful) 2. If leakage threshold ≥150 mL identified, adjust fluid excretion and voiding intervals appropriately 3. Pelvic muscle exercises ± biofeedback/weighted intravaginal cones; must continue indefinitely 4. Surgery (sling, artificial sphincter, periurethral bulking injections)
Urethral obstruction	Urge/overflow‖	1. Conservative methods (including adjustment of fluid excretion, bladder retraining/prompted voiding) if hydronephrosis, recurrent symptomatic UTI, and hematuria have been excluded 2. α-Adrenergic antagonist 3. Also consider adding a bladder relaxant if detrusor overactivity coexists, postvoid residual volume is small, and surgery is not desired/feasible; *monitor postvoid residual volume!* 4. Finasteride, if not contraindicated and the patient either prefers it or is not a surgical candidate 5. Surgery (incision, prostatectomy) is an effective alternative before or after these steps
Underactive detrusor	Overflow	1. Decompress for at least several days (the larger the postvoid residual volume, the longer should be the decompression [up to a month]) and then perform a voiding trial 2. Exclude urethral obstruction if this has not already been done 3. If cannot void or if postvoid residual volume remains large, try augmented voiding techniques¶ ± α-adrenergic antagonist, but only if some voiding possible; bethanechol *rarely* useful 4. If fails, or voiding is not possible, intermittent or indwelling catheterization‡

BLADDER RELAXANT AGENTS FOR URGE INCONTINENCE

- Anticholinergic
  - Oxybutynin IR, 7.5-20 mg daily (2.5-5 mg tid-qid); oxybutynin XL, 5-30 mg once daily; oxybutynin patch (3.9 mg/day) twice weekly; oxybutynin 10% gel (1 g topically once per day)
  - Tolterodine, 1-2 mg twice daily; tolterodine LA, 4 mg once daily
  - Darifenacin, 7.5-15 mg once daily
  - Solifenacin, 5-10 mg once daily
  - Trospium, 20 mg daily to twice daily; 60 mg (extended release) once daily
  - Fesoterodine, 4-8 mg once daily
- β_3-Adrenergic agonist
  - Mirabegron, 25-50 mg once daily

*These treatments should be initiated only after adequate toilet access has been ensured, contributing conditions have been treated (e.g., atrophic vaginitis, UTI, fecal impaction, heart failure), fluid management has been optimized, and unnecessary or exacerbating medications have been addressed. For additional details, see text.
†*Urge:* leakage in the absence of stress maneuvers and urinary retention, usually preceded by *abrupt* onset or intensification of the need to void; *stress:* leakage that coincides *instantaneously* with stress maneuvers, in the absence of urinary retention or detrusor contraction; *overflow:* frequent leakage of small amounts associated with urinary retention.
‡UTI prophylaxis can be used for recurrent symptomatic UTIs, but only if catheter is not indwelling.
§May also mimic stress or overflow incontinence.
‖Also can cause postvoid "dribbling" alone, which is treated conservatively (e.g., by sitting to void and allowing more time, "double voiding," and in men by gently "milking" the urethra after voiding).
¶Augmented voiding techniques include Credé (application of suprapubic pressure) and Valsalva (straining) maneuvers, and double voiding. They should be performed only *after* voiding has begun.
UTI = urinary tract infection.
Adapted and updated in 2014 from Resnick NM. Voiding dysfunction and urinary incontinence. In: Beck JC, ed. *Geriatric Review Syllabus.* New York: American Geriatrics Society; 1991:141-154.

have proved effective for daytime incontinence; pads and diapers are appropriate for the others.[7]

Pharmacotherapy

Currently approved drugs have not proved effective for stress incontinence and overflow incontinence. For urge incontinence, however, several bladder relaxants have proved modestly and equally effective (see Table 26-3), even in trials that targeted older patients.[5,A1,A2,A3] All of the anticholinergics have antimuscarinic properties, such as dry mouth, constipation, visual blurring, and occasional confusion. Yet each is well tolerated even in cognitively impaired elderly patients when prescribed properly, although cognitive status should be monitored.[A4] These drugs also can be well tolerated in patients taking cholinesterase inhibitors. The choice among these drugs often hinges on other considerations. For instance, immediate-release oxybutynin has the quickest onset of action, making it an inexpensive and effective choice for patients who need excellent control at predictable times. The other drugs, although more expensive, can be used less often and can be better tolerated for daily use. Mirabegron, a β_3-adrenergic agonist, is a newer drug with an efficacy similar to the anticholinergic agents.[8]

Regardless of the drug selected, the key is to begin with a low dose and increase it slowly, realizing that the full benefit is generally not apparent for about 2 months and that side effects may offset the benefit. With such titration, urge incontinence can be controlled in about one third of patients and substantially improved in another one third.

Surgical Procedures

Surgery for stress incontinence has proved effective for women of all ages, including elderly women, and is relatively durable.[A1] Periurethral bulking injections can help frail women or those with mild stress incontinence, but it does not generally restore continence. However, urethral sling and mid-urethral tape suspension procedures can cure most women for at least 5 years. For women with more complex stress incontinence and for men with stress incontinence more than 1 year after radical prostatectomy, an artificial sphincter has proved effective and relatively durable. Experience with the "male sling" is still limited.

Surgical interventions for urge incontinence, including neuromodulation,[A9] tibial nerve stimulation,[A10] and injections of onabotulinum toxin,[A11,A12] are third-line agents. However, these procedures have not yet been studied adequately in elderly people. In addition, the limited available data suggest that their efficacy may be only modestly better than that of pharmacotherapy, and that older patients may not fare as well as younger ones.

PREVENTION

There are scant data regarding the prevention of incontinence, but one randomized trial of an educational and behavioral modification program for women older than 55 years found that it reduced the risk for incontinence for 1 year.[A13] A secondary analysis of the Diabetes Prevention Program found that, at the end of 3 years, an intensive lifestyle intervention was associated with reduced risk for self-reported incontinence, with most of the benefit explained by weight loss and a reduced risk for stress incontinence.[A14]

PROGNOSIS

Limited data suggest that incontinence progresses in about one third of patients and remits in about 10 to 15%, although it is unclear how much of the remission reflects intervention or improvement in functional or medical status.

REVIEW QUESTIONS

1. Which of the following is true about acute urinary retention in an older man?

A. Indicates the need for surgical decompression
B. Is treated effectively with α-adrenergic blockers
C. Is treated effectively with bethanechol
D. Requires treatment of the underlying urinary tract abnormality
E. None of the above

Answer: E The differential diagnosis for urinary retention extends beyond urethral obstruction, particularly in elderly people. Many older patients may develop retention owing to a weak detrusor associated with age, autonomic neuropathy, or previous urethral obstruction. In addition, fecal impaction, pain (e.g., following hip replacement), and medications with urinary tract side effects (e.g., anticholinergics, sedating antihistamines, decongestants, opiates) may induce acute urinary retention, particularly in patients with underlying bladder weakness or obstruction. Thus, the bladder should be decompressed for at least a week while reversible causes are addressed; the larger the postvoid residual volume, the longer the decompression should be. Decompression allows some restoration of detrusor strength, which also facilitates urodynamic testing should it be necessary. α-Adrenergic blockers are effective for men with symptoms of prostatism, but clinical trials of its efficacy have excluded patients with significant urinary retention. Bethanechol has not proved effective in controlled clinical trials. Decompression in some elderly patients can reduce but not eliminate residual urine. Provided it does not cause symptoms or renal compromise, subclinical retention need not necessarily be treated in all elderly patients, even if obstruction is present.

2. A 58-year-old obese woman with significant daily stress incontinence comes for a follow-up appointment. Her bladder diary shows maximal voided volume of 125 mL during the daytime. Each of these measures is appropriate except which of the following?

A. Adjustment of fluid excretion and voiding intervals
B. Advise weight reduction
C. Teach her postural maneuvers
D. Consideration of surgical correction
E. Pelvic floor muscle exercises

Answer: A Recent evidence suggests that weight loss will improve stress incontinence in obese women, and data support the use of postural maneuvers, pelvic floor muscle exercises, and surgical correction as well. Adjusting fluid excretion and voiding intervals can also be useful, especially for women with volume-dependent stress leakage. It can work particularly well for women with a threshold of at least 150 mL and best in those with a threshold of more than 250 mL. When the threshold for stress incontinence is this low, however, the extent of fluid restriction required is usually not feasible and might even lead to dangerous dehydration.

3. A 78-year-old woman with dementia has responded modestly to donepezil (Aricept, a cholinesterase inhibitor) for the past year. The recent onset of urge incontinence led her primary physician to prescribe tolterodine last month while awaiting your assessment. Her incontinence has responded well. The next appropriate step is which of the following?

A. Discontinue tolterodine because of its interaction with donepezil.
B. Discontinue donepezil because her cognitive function is stable.
C. Discontinue both drugs because she is stable and the urge incontinence may reflect an adverse effect of the donepezil.
D. Continue both drugs and monitor her for deterioration in cognitive function.
E. Taper the tolterodine.

Answer: D Because cholinesterase inhibitors block the metabolism of acetylcholine, they can provoke urge incontinence, especially in older adults who already may have underlying age-related involuntary detrusor contractions that have not yet caused incontinence. However, despite prescription of these agents to millions of demented patients, there is little evidence that they cause incontinence. Moreover, because the benefits of these drugs for dementia are modest at best and not seen in most patients who use them, patients and families may decide that the benefit of the bladder relaxant outweighs the risk. Particularly in this patient, who has already benefited from tolterodine without notable cognitive deterioration, it is worth continuing therapy and monitoring her cognitive status.

4. A 53-year-old woman says that she has frequent leakage. It most commonly occurs about 10 seconds after she coughs or laughs. Having suffered for years, she is interested in the approach with the best chance of success.

A. Pelvic muscle strengthening exercises ("Kegels")
B. An α-adrenergic agonist (e.g., pseudoephedrine)
C. A pessary
D. Urethral suspension surgery
E. A bladder relaxant drug

Answer: E Most stress incontinence results from weakness of intrinsic sphincter muscle or pelvic muscle support. In all such cases, however, leakage coincides instantaneously with the increase in abdominal pressure and ceases as soon as the cough ends. In this case, however, there is a delay between the cough and leakage. This finding suggests that the cough has triggered an involuntary detrusor contraction, which then leads to leakage. Therapy should focus on reducing or eliminating the precipitant of coughing (e.g., bronchospasm, use of an angiotensin-converting enzyme inhibitor) or the underlying detrusor overactivity.

5. Which of the following is true of incontinence in demented elderly patients?

A. Is inevitable
B. Is virtually always due to detrusor overactivity/overactive bladder
C. Is unlikely to respond to therapy
D. Is multifactorial and often reversible
E. Treatment should focus primarily on preventing skin breakdown

Answer: D Incontinence is never normal, even in patients with dementia. Detrusor overactivity is the most common type of lower urinary tract dysfunction among demented and incontinent nursing home residents, but it is also the most common dysfunction among their dry peers. Moreover, in 40% of these individuals, incontinence is not associated with detrusor overactivity but with obstruction (in men), stress incontinence (in women), or a combination of an outlet and a detrusor problem, and the cause does not correlate with either the presence or severity of dementia. Thus, it is not tenable to attribute incontinence *a priori* to detrusor overactivity. Because incontinence in elderly people is usually multifactorial, involving urinary tract as well as non–urinary tract contributions, it is often treatable. Even among nursing home patients, randomized studies of just a toileting regimen have shown more than a 50% reduction in incontinent episodes overall and full daytime continence in nearly 40% of residents. Because causes of transient incontinence are particularly common in demented individuals, additional benefit can be achieved by addressing other common contributors to their incontinence, including medication use, depression, fecal impaction, urinary tract infection, atrophic vaginitis, and disorders of fluid excretion. For those with detrusor overactivity, a bladder relaxant may provide additional help; for those with urethral obstruction or incompetence, minimally invasive procedures can be helpful. It is also important to prevent skin breakdown, but such treatment should not be the primary approach to the incontinent nursing home resident.

27 NEUROPSYCHIATRIC ASPECTS OF AGING

SHARON K. INOUYE

DEFINITION

The process of aging produces important physiologic changes in the central nervous system (Table 27-1), including neuroanatomic, neurotransmitter, and neurophysiologic changes. These processes result in age-related symptoms and manifestations (Table 27-2) for many older persons. These physiologic changes develop at dramatically variable rates among older persons, however, and the decline may be modified by factors such as diet, exercise, environment, lifestyle, genetic predisposition, disability, disease, and side effects of drugs. These changes can result in the common age-related symptoms of benign senescence, slowed reaction time, postural hypotension, vertigo or giddiness, presbyopia, presbycusis, stiffened gait, and sleep difficulties. In the absence of disease, these physiologic changes usually result in relatively modest symptoms and little restriction in activities of daily living. These changes decrease physiologic reserve, however, and increase the susceptibility to challenges posed by disease-related, pharmacologic, and environmental stressors. As a result, mild (relative risk, 1.2) and moderate (relative risk, 1.4) cognitive impairment are associated with increased mortality.[1]

EPIDEMIOLOGY

Neuropsychiatric disorders, the leading cause of disability in older persons, account for nearly 50% of functional incapacity. Severe neuropsychiatric conditions have been estimated to occur in 15 to 25% of older adults worldwide. These conditions are due to diseases that increase with age but are not part of the normal aging process. Alzheimer disease and related dementias occur in approximately 10% of adults aged 65 years and older and in 40% of

TABLE 27-1 AGE-RELATED PHYSIOLOGIC CHANGES IN THE CENTRAL NERVOUS SYSTEM

Neuroanatomic changes
Brain atrophy
Decreased neuron counts
Increased neuritic plaques
Increased lipofuscin and melanin
Neurotransmitter changes
Decline in cholinergic transmission
Decreased dopaminergic synthesis
Decreased catecholamine synthesis
Neurophysiologic changes
Decreased cerebral blood flow
Electrophysiologic changes (slowing of alpha rhythm, increased latencies in evoked responses)

TABLE 27-2 NEUROPSYCHIATRIC MANIFESTATIONS OF AGE-RELATED PHYSIOLOGIC CHANGES

SYSTEM	MANIFESTATION
Cognition	Forgetfulness Processing speed declines throughout adult life Neuropsychological declines: selective attention, verbal fluency, retrieval, complex visual perception, logical analysis
Reflexes	Stretch reflexes lose sensitivity Decreased or absent ankle reflexes Decreased autonomic and righting reflexes, postural instability
Sensory	Presbycusis (high-frequency hearing loss), tinnitus Deterioration of vestibular system, vertigo Presbyopia (decreased lens elasticity) Slowed pupil reactivity, decreased upgaze Olfactory system deterioration Decreased vibratory sensation
Gait and balance	Gait stiffer, slowed, forward flexed Increased body sway and mild unsteadiness
Sleep	Decreased sleep efficiency, fatigue Increased awakenings, insomnia Decrease in sleep stages 3 and 4 Sleep duration more variable, more naps

7. Do you feel happy most of the time?	yes/**NO**
8. Do you feel helpless?	**YES**/no
9. Do you prefer to stay home rather than going out and doing new things?	**YES**/no
10. Do you feel you have more problems with memory than most?	**YES**/no
11. Do you think it is wonderful to be alive now?	yes/**NO**
12. Do you feel pretty worthless the way you are now?	**YES**/no
13. Do you feel full of energy?	yes/**NO**
14. Do you feel that your situation is hopeless?	**YES**/no
15. Do you think that most people are better off than you are?	**YES**/no

Scoring: Answers indicating depression are capitalized; six or more capitalized answers indicate depressive symptoms.
Modified with permission from Yesavage J, Brink T, Rowe T, et al. Development and validation of a geriatric depression screening scale: a preliminary report. *J Psychiatr Res.* 1983;17:37-49.

those older than 85 years (Chapter 402). Delirium occurs in 5 to 10% of all persons older than 65 years and in up to 80% of older persons during hospitalizations for acute illnesses (Chapter 28). Severe depression (Chapter 397) occurs in approximately 5% of older adults, with 15% having significant depressive symptoms. Anxiety disorders occur in 10% of older adults. Older individuals are also subject to substantial morbidity and functional disability from cerebrovascular disease (Chapters 406 through 408), Parkinson disease (Chapter 409), peripheral neuropathies (Chapter 420), degenerative myelopathies (Chapters 400 and 422), spinal stenosis and disc disease (Chapter 400), seizure disorders (Chapter 403), sleep apnea (Chapter 100), visual disturbances (Chapter 423), falls (Chapter 25), incontinence (Chapter 26), and impotence (Chapter 234).

DIAGNOSIS

To diagnose these neuropsychiatric conditions, physicians must understand and perform a mental status examination and an assessment of functional capacity and know the uses and side effects of psychoactive drugs in geriatric patients.

Mental Status Examination

In addition to a detailed neurologic examination, evaluation of neuropsychiatric disturbances in older persons requires a careful mental status examination, including an assessment of mood, affect, and cognition. Brief screening tests are available to evaluate these domains and to assist in the detection of potential problems requiring further evaluation and treatment (see Chapter 24). Scores of 6 or more on the 15-item short-form Geriatric Depression Scale (Table 27-3) indicate substantial depressive symptoms requiring further evaluation. For cognitively impaired patients, observer (proxy)–rated depression scales, such as the Hamilton Depression Scale or Cornell Scale, are recommended.

Early cognitive deficits can easily be missed during conversation because intellectual impairment can be masked with intact social skills. Given the high frequency of cognitive impairment, formal cognitive screening is reasonable but not required for all older persons.[2] Ideally, cognitive testing should evaluate at least the general domains of attention, orientation, language, memory, visuospatial ability, and conceptualization. To exclude delirium, attention should be assessed first by asking the patient to perform a task, such as repeating digits (normal span: more than five forward or more than three backward) or reciting the months backward (allow one error maximum); the remainder of cognitive testing would not be useful in an inattentive or delirious patient. For further cognitive testing, many brief, practical screening instruments are available. Historically, the most widely used instrument has been the Mini-Mental State Examination, a 19-item, 30-point scale that can be completed in 10 minutes. This copyrighted instrument now requires a per-use fee if the official version is used. Useful, brief alternative instruments include the Short Portable Mental Status Questionnaire (Table 27-4) and the Mini-Cog

TABLE 27-4 SHORT PORTABLE MENTAL STATUS QUESTIONNAIRE

QUESTION	RESPONSE			ERROR?
What are the date, month, and year?*	Date	Month	Year	
What is the day of the week?				
What is the name of this place?				
What is your phone number?				
How old are you?				
When were you born?				
Who is the current president?				
Who was the president before him?				
What was your mother's maiden name?				
Can you count backward from 20 by 3s?				

*A mistake on *any* part of this question should be scored as an error.
Total possible errors: 10; more than three errors indicates cognitive impairment.
From Pfeiffer E. A short portable mental status questionnaire for the assessment of organic brain deficit in elderly patients. *J Am Geriatr Soc.* 1975;23:433-441. Copyright © E. Pfeiffer 1994. Reproduced with permission of the author.

TABLE 27-5 MINI-COG TEST

1. Instruct the patient to listen carefully to and remember three unrelated words and then to repeat the words: banana, sunrise, chair.
2. Instruct the patient to draw the face of a clock, either on a blank sheet of paper or on a sheet with a large circle already drawn on the page. After the patient puts the numbers on the clock face, ask him or her to draw the hands of the clock to read a specific time, such as 11:10. These instructions can be repeated, but no additional instructions should be given. Allow up to 3 minutes to complete the clock drawing.
3. Ask the patient to repeat the three previously presented words.
4. Give 1 point for each correct word and 2 points for a correctly drawn clock. Scores <3 suggest cognitive impairment.

Modified from Borson S, Scanlan J, Watanabe J, et al. Improving identification of cognitive impairment in primary care. *Int J Geriatr Psychiatry.* 2006;21:349-355. Reprinted by permission of the copyright holder (S. Borson).

test (Table 27-5), both of which can be completed in less than 5 minutes. More detailed testing can be conducted with the Montreal Cognitive Assessment (Fig. 27-1), which requires 15 to 20 minutes; scores less than 26 indicate cognitive impairment. Questions to evaluate judgment and problem-solving ability in hypothetical situations, such as in a fire or when driving,

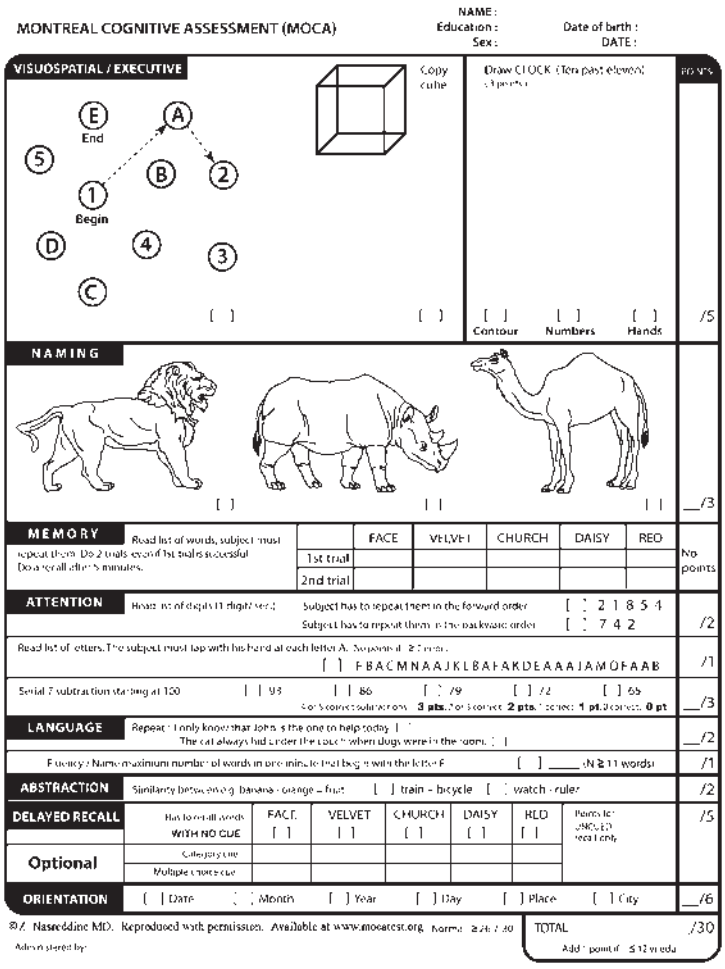

FIGURE 27-1. Montreal Cognitive Assessment. (Reproduced with permission from Nasreddine ZS, Phillips NA, Bedirian V, et al. The Montreal Cognitive Assessment, MoCA: A brief screening tool for mild cognitive impairment. *J Am Geriatr Soc.* 2005;53:695-699.)

can provide crucial insight into the patient's ability to function safely and independently.

Functional Assessment

Functional impairment, defined as difficulty in performing daily activities, is common among older persons. Although it is not routinely evaluated in the standard medical assessment, determination of the patient's degree of functional incapacity based on medical and neuropsychiatric conditions is crucial to diagnosis of mild cognitive impairment and dementia as well as to understanding of the burden of the disease and its impact on the individual's daily life. The important relationship between functional status and health in older persons is reflected by the finding that functional measures are stronger predictors of mortality after hospitalization than are admitting diagnoses. Functional measures strongly predict other important long-term outcomes in the elderly, such as future care needs, caregiver burden, risk for institutionalization, and long-term prognosis.[3] Functional independence is critical if patients are to remain living independently in the community, and functional decline represents the leading risk factor for nursing home placement.

The functional assessment should evaluate the patient's ability to perform basic self-care activities of daily living and instrumental activities of daily living, the higher level activities needed for independent living. Activities of daily living include basic self-care skills, such as feeding, grooming, bathing, dressing, toileting, transferring, and walking. Instrumental activities of daily living are more complex tasks, including shopping, preparing meals, managing finances, housekeeping, using the telephone, taking medications, and driving or using public transportation. The functional assessment is conducted with the patient, with corroboration from a family member or caregiver. Other related domains that should be assessed include vision, hearing, continence, nutritional status, safety, falls, living situation, availability of social support, and socioeconomic status.

The onset of acute cognitive or functional decline is often the first and sometimes the only sign of serious acute illness in older persons and warrants immediate medical attention. Similarly, the onset or worsening of related conditions, such as delirium, falls, incontinence, depression, frailty, or failure to thrive, heralds the need for prompt medical evaluation.

TREATMENT

Psychoactive Effects of Drugs in Older Patients

Adverse Drug Events in the Elderly

Iatrogenic complications occur in 29 to 38% of older hospitalized patients, with a 3- to 5-fold increased risk in older compared with younger patients. Adverse drug events, the most common type of iatrogenic complication, account for 20 to 40% of all complications, and at least 27% of these are preventable.[4] The elderly are particularly vulnerable to adverse drug reactions because of multiple-drug regimens, multiple chronic diseases, relative renal and hepatic insufficiency, decreased physiologic reserve, and altered drug metabolism and receptor sensitivity with aging.[5] Inappropriate drug use has been reported in up to 40% of older patients who are hospitalized, with more than one quarter of these patients having absolute contraindications to the drug and the others being given a drug that was unnecessary. Among an estimated 100,000 annual drug-related emergency hospitalizations in patients older than 65 years, the most commonly implicated drugs are warfarin (33%), insulin (14%), oral antiplatelet agents (13%), and oral hypoglycemic agents (11%).[6] Because up to 50% of adverse drug events occur in patients receiving inappropriate drugs, the potential for reducing these adverse events is substantial.

Drugs with Psychoactive Effects

Nearly every class of drug has the potential to cause mental status changes in a vulnerable patient, but specific drugs are commonly implicated (Table 27-6) and should be used with caution in older patients.[6] Many cases of delirium or cognitive decline in older patients may be preventable through avoidance, substitution, or dose reduction of these psychoactive drugs. Long-acting benzodiazepines (e.g., diazepam, clonazepam, chlordiazepoxide) are particularly problematic medications for the elderly and should not be used to treat insomnia. If nonpharmacologic approaches to the management of insomnia are unsuccessful, short-term use of an intermediate-acting benzodiazepine without active metabolites (e.g., lorazepam 0.5 mg, half-life of 10 to 15 hours) is recommended. Drugs with anticholinergic effects (e.g., antihistamines, antidepressants, neuroleptics, antispasmodics) produce a panoply of poorly tolerated side effects in older patients, including delirium, postural hypotension, urinary retention, constipation, and dry mouth. Of the narcotics, meperidine causes delirium more frequently than other agents because of an active metabolite, normeperidine. Cardiac drugs, such as digitalis and antiarrhythmic agents, have prolonged half-lives, narrowed therapeutic windows, and decreased protein binding in older patients. The clinician should be aware that toxicity with these agents (e.g., digoxin) can occur even at therapeutic drug levels. The H_2-receptor antagonists (e.g., cimetidine, ranitidine, famotidine, nizatidine) are among the most common causes of drug-induced delirium in the elderly because of their frequent use; clinicians should strongly consider the use of less toxic alternatives (e.g., sucralfate, antacids) or dosage reductions for older patients, especially when the medication is being used for prophylaxis rather than treatment of active disease. Proton pump inhibitors have been associated with delirium in case reports but have less neuropsychiatric toxicity than H_2-receptor antagonists.

Psychoactive drugs account for nearly 50% of preventable adverse drug events, often in patients who have been prescribed three or more psychoactive drugs, frequently at inappropriately high doses in the elderly. Delirium and cognitive impairment are the most frequent adverse outcomes of psychoactive drugs. The use of any psychoactive drug is associated with a 4-fold increased risk of delirium or cognitive decline, but the outcomes of these conditions depend on the type or class of drug administered and the total number of drugs received. Sedative-hypnotic drugs are associated with a 3- to 12-fold increased risk for delirium or cognitive decline, narcotics are associated with a 2- to 3-fold increased risk, and anticholinergic drugs are associated with a 5- to 12-fold increased risk. Each drug carries its own individual risk for adverse outcomes, and when multiple drugs are used, the overall risk is compounded by the heightened potential for drug-drug and drug-disease interactions. If more than three drugs are added in a 24-hour period, the risk of delirium increases 4-fold. Similarly, the risk of cognitive decline increases directly with the number of drugs prescribed, from a 3-fold increased risk with two or three drugs to a 14-fold increased risk with six or more drugs.

Principles of Drug Therapy in the Elderly

Physicians always should consider whether nonpharmacologic approaches (Chapter 39) may be used as alternatives to medications in older persons. Relaxation techniques, massage, and music are highly effective for the treatment of insomnia and anxiety; localized pain can often be managed effectively

TABLE 27-6 DRUGS WITH PSYCHOACTIVE EFFECTS

Sedative-hypnotics
Benzodiazepines (especially flurazepam, diazepam)
Barbiturates
Sleeping medications (chloral hydrate)
Narcotics (especially meperidine)
Anticholinergics
Antihistamines (diphenhydramine, hydroxyzine)
Antispasmodics (belladonna, Lomotil)
Heterocyclic antidepressants (amitriptyline, imipramine, doxepin)
Neuroleptics (chlorpromazine, haloperidol, thioridazine)
Antiparkinson drugs (benztropine, trihexyphenidyl)
Atropine, scopolamine
Cardiac drugs
Digitalis glycosides
Antiarrhythmics (quinidine, procainamide, lidocaine)
Antihypertensives (β-blockers, methyldopa)
Gastrointestinal drugs
H_2-receptor antagonists (cimetidine, ranitidine, famotidine, nizatidine)
Proton pump inhibitors (esomeprazole, lansoprazole, omeprazole, pantoprazole)
Metoclopramide (Reglan)
Miscellaneous drugs
Nonsteroidal anti-inflammatory drugs
Corticosteroids
Anticonvulsants
Levodopa
Lithium
Over-the-counter drugs
Cold and sinus preparations (antihistamines, pseudoephedrine)
Sleep aids (diphenhydramine, alcohol-containing elixirs)
Stay Awake (caffeine)
Nausea, gastrointestinal relief (Donnagel, meclizine, H_2-receptor antagonists, loperamide)

TABLE 27-7 GUIDELINES FOR DRUG THERAPY IN THE ELDERLY

GENERAL PRINCIPLES
Remember that the elderly are highly sensitive to the psychoactive effects of all drugs.
Know the pharmacology of the drugs you prescribe. Know a few drugs well.
RECOMMENDED APPROACH
Use nonpharmacologic approaches whenever possible.
Avoid *routine* use of "as needed" drugs for sleep, anxiety, pain.
Choose the drug with the least toxic potential.
Substitute less toxic alternatives whenever possible (antacid or sucralfate for an H_2-blocker or proton pump inhibitors, Metamucil or Kaopectate for Imodium or Lomotil, scheduled acetaminophen regimen for pain management).
Reduce the dosage.
"Start low and go slow."
Start with 25 to 50% of the standard dose of psychoactive drugs in the elderly.
Titrate the drug slowly.
Set realistic end points: titrate to improvement, not elimination of symptoms.
Keep the regimen simple.
Regularly reassess the medication list. Have the patient bring in all bottles and review what is being taken.
Reevaluate long-time drug use because the patient is changing.
Review over-the-counter medications, including herbal remedies.

with local measures such as injection, heat, ultrasound, and transcutaneous electrical stimulation.

When drug therapy is required in the elderly, physicians should choose the drug with the least toxic potential and emphasize drugs that have been well tested in older populations (Table 27-7). It is often wise to start with 25 to 50% of the standard adult dosage for a psychoactive drug and to increase the dose slowly. Drug regimens should be kept simple, with the fewest drugs and the fewest number of pills possible. Most important, the medication list should be reassessed frequently. Involving a clinical pharmacist in the care team can significantly improve healthcare outcomes.[A1] Systematic interventions involving geriatricians, clinical pharmacists, and computer-based monitoring systems also can significantly reduce the frequency of adverse drug reactions in older persons.[A2]

For persons with dementia or cognitive impairment, the following classes of drugs should be avoided or discontinued if possible: benzodiazepines, H_2-receptor antagonists, meperidine, sedative-hypnotics, and thioridazine.[4] Even long-standing medications should be reevaluated as the patient changes with age and illness. Long-term use does not justify continued use. The physician should review with the patient all prescribed and over-the-counter medications on a regular basis, preferably by having the patient bring in all medication bottles and indicate how each is being taken. Patients frequently underestimate the toxic potential of over-the-counter medications and herbal remedies, and they may be using a variety of such agents that could potentiate the side effects or directly counteract the desired effects of prescription medications (Chapter 29). For example, high-risk over-the-counter medications for older persons include nonsteroidal anti-inflammatory agents, H_2-blockers, and antihistamines. In addition, herbal remedies may interact with warfarin either to increase or to decrease its effect (St. John's wort decreases the effect and makes anticoagulation more difficult; gingko biloba increases the effect and may cause bleeding)[7]; others (such as kava kava, echinacea, and Chinese herbal preparations) have been associated with the risk of hepatotoxicity.

REVIEW QUESTIONS

1. An 82-year-old woman with atrial fibrillation, congestive heart failure, hyperlipidemia, diabetes mellitus, and hypertension is brought to you by her daughter for evaluation of the acute onset of disorientation and agitation. Her medications include furosemide, metoprolol, atorvastatin, sertraline, warfarin, ranitidine, amlodipine, and an over-the-counter sleep remedy containing diphenhydramine. Which of her medications are *most likely* to be contributing to her altered mental status?

A. Furosemide, metoprolol, and amlodipine
B. Warfarin, atorvastatin, and sertraline
C. Sertraline, ranitidine, and diphenhydramine
D. Diphenhydramine, warfarin, and metoprolol
E. Atorvastatin, furosemide, and sertraline

Answer: C Drugs with psychoactive side effects are most likely contributing to this patient's altered mental status. Anticholinergic drugs (such as diphenhydramine) are common contributors to mental status changes. Over-the-counter medications containing these agents should be used with caution in older persons. H_2-receptor blockers are among the most common drugs contributing to delirium. Antidepressants may also contribute to mental status changes, even at therapeutic levels. Choice A is not correct because these drugs are not highly correlated with mental status changes, although metoprolol can cross the blood-brain barrier. A major adverse effect of this combination in the elderly is orthostatic hypotension. All of the other combinations have only one drug listed that has marked psychoactive effects.

2. A 78-year-old man with hypertension, peripheral vascular disease, osteoarthritis of the knees, and macular degeneration is brought in by his daughter for evaluation of confusion and "failure to thrive" after a flu-like illness 2 months ago. The daughter reports that during the past few weeks, her father has been drowsy and sleeping most of the day. His memory is poor at times, but he remains independent in all self-care activities. Normally active, he has stopped his usual gardening and walking and shows little interest in interacting with his grandchildren, which he normally enjoys. His appetite is poor, and he has lost weight. Your examination reveals a flattened affect with poor eye contact. Neurologic examination is nonfocal without cogwheeling or tremor. On the Short Portable Mental Status Questionnaire, he has two errors after initially poor effort, which improved after extensive prompting and encouragement. He scores 7 of 15 on the Geriatric Depression Scale. What is the most likely diagnosis?

A. Early-onset Parkinson disease
B. Mild cognitive impairment
C. Early dementia (combined vascular and Alzheimer type)
D. Post–viral encephalitis
E. Major depressive disorder

Answer: E This patient demonstrates symptoms of a major depressive disorder, including anhedonia, loss of interest in his usual activities, excessive sleep, loss of appetite, and weight loss. His cognitive screening test reveals cognitive "dilapidation" with poor effort, sometimes called a pseudodementia. His depression screening reveals marked depressive symptoms. In older persons, somatic symptoms are often more prominent than mood complaints. This patient should be referred for immediate geropsychiatric evaluation and management. Precipitants are not always present, but bereavement and acute or chronic medical conditions can contribute. There is no evidence of Parkinson disease, and the patient does not meet criteria for mild cognitive impairment or dementia.

3. Older persons are at least three times more likely than younger persons to experience an adverse drug reaction. All of the following contribute to this propensity *except* which one?

A. Greater number of drugs
B. Multiple chronic conditions
C. Decreased glomerular filtration rate
D. Decreased hepatic function
E. Increased physiologic reserve

Answer: E Because of a greater number of drugs and chronic conditions, the elderly are at increased risk of drug-drug and drug-disease interactions. In addition, renal and hepatic functioning are relatively decreased, as is physiologic reserve capacity. Drug receptor sensitivity can be either increased or decreased, depending on the drug and receptor regulation.

4. An 86-year-old widowed woman living alone with peripheral vascular disease, lower extremity amputation, hypertension, and old stroke without residua is brought in by her neighbor for increasing forgetfulness during the past year. Your examination reveals a cheerful, interactive, and well-groomed woman with normal findings on neurologic examination. She has five errors on the Short Portable Mental Status Questionnaire. What is the most appropriate next step in her evaluation?

A. Obtain brain imaging and lumbar puncture
B. Assess her activities of daily living and level of independence
C. Initiate treatment with an acetylcholinesterase inhibitor
D. Initiate treatment with an antidepressant
E. Refer her for nursing home placement

Answer: B Assessment of activities of daily living (both basic and instrumental) is key to the diagnosis of dementia, and information must often be obtained from a reliable informant. This is the important next step in the evaluation. Dementia can be diagnosed only in the presence of a functional impairment. After this assessment is complete, further evaluation can include laboratory work, neuroimaging, and other testing as required. Her ability to live independently must also be assessed, and social work involvement is recommended after a diagnosis is established.

28

DELIRIUM OR ACUTE MENTAL STATUS CHANGE IN THE OLDER PATIENT

SHARON K. INOUYE

Mental status change, one of the most common presenting symptoms in acutely ill elders, is estimated to account for 30% of emergency evaluations among older patients. Mental status often serves as a barometer of the underlying health of an elderly patient and is commonly the only symptom of serious underlying disease. A broad range of medical, neurologic, and psychiatric conditions can lead to mental status changes (Chapters 397 and 402). A systematic approach aids in the evaluation of suspected mental status change in an older patient (Fig. 28-1).

The first step in evaluating suspected altered mental status in an older patient is to obtain a detailed history from a reliable informant to establish the patient's baseline level of cognitive function and the clinical course of any cognitive changes. Chronic changes (those occurring during months to years) most likely represent an underlying dementing illness and should be evaluated accordingly (Chapter 402). Acute changes (those occurring during days to weeks)—even if superimposed on an underlying dementia—should be evaluated by a formal cognitive assessment to determine whether delirium is present. If features of delirium (e.g., inattention, disorganized thinking, altered level of consciousness, fluctuating symptoms) are not present, further evaluation for depression, acute nonorganic psychotic disorders, or other psychiatric conditions is indicated.

DELIRIUM

Delirium, a clinical syndrome characterized as an acute disorder of attention and cognitive function, is the most frequent complication of hospitalization for elders and is a potentially devastating problem. Delirium is often unrecognized despite sensitive methods for its detection, and its complications may be preventable.

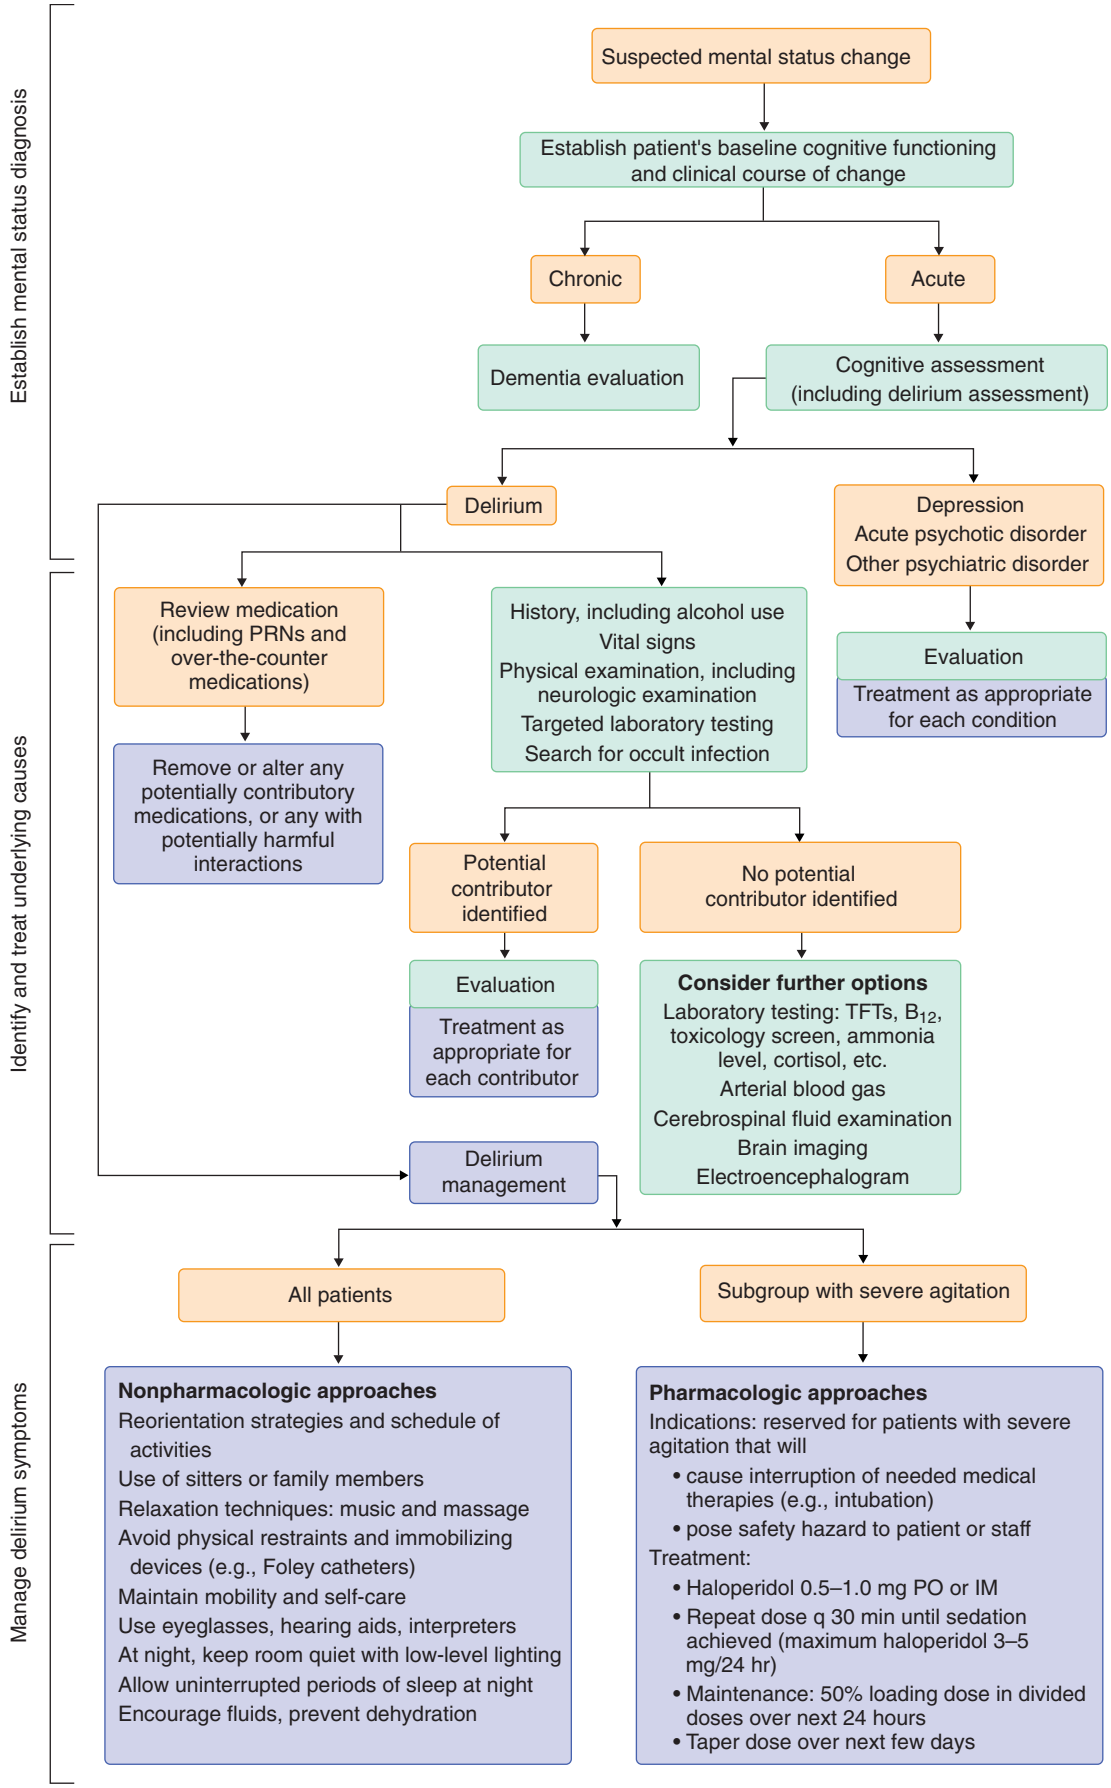

FIGURE 28-1. Algorithm for the evaluation of suspected mental status change in older patients. PRN = as needed; TFTs = thyroid function tests.

TABLE 28-1 DIAGNOSTIC CRITERIA FOR DELIRIUM

DSM-5 CRITERIA*

- Disturbed attention (i.e., reduced ability to direct, focus, sustain, and shift attention) and awareness (reduced orientation to the environment) that has developed in a short time (usually hours to a few days), represents a change from baseline attention and awareness, and tends to fluctuate in severity during the course of a day
- An additional disturbance in cognition (e.g., memory deficit, disorientation, language, visuospatial ability, or perception)
- Evidence from the history, physical examination, or laboratory findings that the disturbance is a direct physiologic consequence of another medical condition, substance intoxication or withdrawal, exposure to a toxin, or multiple causes
- No evidence for another preexisting, established, or evolving neurocognitive disorder to explain the inattention and cognitive disturbance
- No evidence for a reduced level of arousal, such as coma

CAM DIAGNOSTIC ALGORITHM†

Feature 1. Acute onset and fluctuating course. This information is usually obtained from a family member or nurse and is shown by positive responses to the following questions: Is there evidence of an acute change in mental status from the patient's baseline? Did the (abnormal) behavior fluctuate during the day—that is, tend to come and go or increase and decrease in severity?

Feature 2. Inattention. This feature is shown by a positive response to the following question: Did the patient have difficulty focusing attention—for example, was he or she easily distracted or did he or she have difficulty keeping track of what was being said?

Feature 3. Disorganized thinking. This feature is shown by a positive response to the following question: Was the patient's thinking disorganized or incoherent, such as rambling or irrelevant conversation, unclear or illogical flow of ideas, or unpredictable switching from subject to subject?

Feature 4. Altered level of consciousness. This feature is shown by any answer other than "alert" to the following question: Overall, how would you rate this patient's level of consciousness: alert (normal), vigilant (hyperalert), lethargic (drowsy, easily aroused), stupor (difficult to arouse), or coma (unable to arouse)?

†The diagnosis of delirium requires the presence of features 1 and 2 and either 3 or 4. CAM = Confusion Assessment Method. From Inouye SK, van Dyck CH, Alessi CA, et al. Clarifying confusion: The Confusion Assessment Method. A new method for detection of delirium. *Ann Intern Med.* 1990;113:941-948. Copyright 2003, Hospital Elder Life Program, LLC. Not to be reproduced without permission.

DEFINITION

The diagnostic criteria for delirium are evolving (Table 28-1). The *Diagnostic and Statistical Manual of Mental Disorders* is based on expert consensus, but the diagnostic sensitivity and specificity of its criteria have not been tested. The Confusion Assessment Method provides a simple, operationalized diagnostic algorithm.[1] In studies of more than 1000 subjects, it had a sensitivity of 94%, a specificity of 89%, and a high interrater reliability.

EPIDEMIOLOGY

In persons older than 65 years admitted to general medical services, the prevalence of delirium at hospital admission is 18 to 35%. Delirium develops anew in an additional 11 to 14% of these patients during hospitalization. Higher rates are found when frequent surveillance is performed in older, surgical, and intensive care populations. Delirium occurs in 10 to 70% of postoperative patients, up to 80% of patients in medical intensive care units, up to 35% of nursing home patients, and at least 45% of patients at the end of life.[1]

The hospital mortality rates for delirium are 25 to 33%, as high as those associated with sepsis. The problem of delirium in hospitalized elderly patients has assumed particular prominence because patients aged 65 years and older currently account for more than 50% of all inpatient days of hospital care. Based on U.S. vital health statistics, delirium complicates hospital stays for at least 20% of the 12.5 million older persons hospitalized each year and increases hospital costs by more than $3000 per patient, amounting to more than $9 billion of Medicare expenditures yearly. Substantial additional costs are incurred after hospital discharge because of the increased need for rehabilitation services, nursing home placement, home care, and rehospitalization. Health care costs associated with delirium range from $50 billion to $200 billion per year. These extrapolations highlight the extensive economic and health policy implications of delirium.

PATHOBIOLOGY

Similar to other common geriatric syndromes (Chapter 25), delirium usually has multiple causes. A search for the innumerable potential underlying contributors requires clinical astuteness and a thorough medical evaluation, especially because many of these factors are treatable but may result in substantial morbidity and mortality if left untreated. The process is made more challenging by the frequently nonspecific, atypical, or muted features of the underlying illness in older persons. Delirium is commonly the only initial sign of an underlying life-threatening illness, such as pneumonia (Chapter 97), urosepsis (Chapter 284), or myocardial infarction (Chapter 73) in the older population.

The basic pathogenesis of delirium remains unclear. Recent evidence suggests that interacting biologic factors result in disruption of large-scale neuronal networks in the brain, thereby leading to acute cognitive disruption and delirium. Some of the leading proposed mechanisms include disruption in neurotransmitter systems, inflammation, physiologic stressors, metabolic derangements, electrolyte and acid-base disorders, and genetic factors. Many neurotransmitter systems are potentially involved, but relative cholinergic deficiency and dopamine excess are the most frequently linked. Inflammation may operate through both peripheral and central (brain) inflammatory cascades. Neuroimaging studies coupled with cognitive testing demonstrate a generalized disruption in higher cortical function, with dysfunction in the prefrontal cortex, frontal and temporoparietal cortex, fusiform cortex, lingual gyri, subcortical structures, thalamus, and basal ganglia.

The development of delirium usually involves a complex interrelationship between a vulnerable patient with pertinent predisposing factors and exposure to noxious insults or precipitating factors. Delirium may develop in vulnerable patients, such as cognitively impaired or severely ill patients, after a relatively benign insult, such as a single dose of sleeping medication. Conversely, in patients who are not vulnerable, delirium may develop only after exposure to multiple noxious insults. Previous studies have shown that the effects of these risk factors may be cumulative. Recognition of this multifactorial causation is important to the clinician because the removal or treatment of one factor in isolation usually is not sufficient to resolve the delirium. The full spectrum of vulnerability and precipitating factors should be addressed.

Factors that predispose patients to delirium include preexisting cognitive impairment or dementia, history of delirium, functional impairment, visual or hearing impairment, multiple comorbid conditions, severe underlying illness, depression, history of a stroke or transient ischemic attack, alcohol abuse, and advanced age. Dementia is an important and consistent risk factor for delirium; persons with dementia have a two-fold to five-fold increased risk for delirium, and 30 to 50% of delirious patients have underlying dementia.

Medications, the most common remediable causes of delirium, contribute to delirium in 40% of cases (Chapter 27). Insufficiency or failure of any major organ system, particularly renal or hepatic failure, can precipitate delirium. Surgical procedures are leading risk factors for delirium. Hypoxemia and hypercarbia have been associated with delirium. Clinicians must be attuned to occult respiratory failure, which in the elderly often lacks the usual signs and symptoms of dyspnea and tachypnea and can be missed by the measurement of oxygen saturation alone. Acute myocardial infarction or heart failure can be manifested as delirium in an elderly patient without the usual symptoms of chest pain or dyspnea. Occult infection is a particularly notable cause of delirium. Older patients frequently fail to mount the febrile or leukocytotic response to infection, and clinicians must assess them carefully for signs of pneumonia, urinary tract infection, endocarditis, abdominal abscess, or infected joints. A variety of metabolic disorders may contribute to delirium, including hypernatremia and hyponatremia, hypercalcemia, acid-base disorders, hypoglycemia and hyperglycemia, and thyroid or adrenal disorders. Immobilization and immobilizing devices (e.g., indwelling bladder catheters, physical restraints, bed alarms) are important factors in precipitating delirium. Dehydration and volume depletion and nutritional decline during hospitalization (e.g., weight loss, fall in serum albumin concentration) are well-documented factors contributing to delirium. Drug and alcohol withdrawal are important and often unsuspected causes of delirium in the elderly. Environmental factors, such as unfamiliar surroundings, sleep deprivation, deranged schedule, frequent room changes, sensory overload, and sensory deprivation, may aggravate delirium in the hospital. Psychosocial factors, such as depression, psychological stress, pain, and lack of social supports, also may precipitate delirium.

CLINICAL MANIFESTATIONS

The cardinal features of delirium include acute onset and inattention. Establishing the acuteness of onset requires accurate knowledge of the patient's baseline cognitive function. Patients with delirium are inattentive; that is,

they have difficulty focusing, maintaining, and shifting attention. They appear easily distracted and have difficulty in maintaining conversation and following commands. Objectively, patients may have difficulty with simple repetitive tasks, digit spans, and recitation of months backward. Other key features include disorganized thought processes, which are usually a manifestation of underlying cognitive or perceptual disturbances; altered level of consciousness, which typically consists of lethargy with reduced awareness of the environment; and fluctuation of cognitive symptoms. Although not cardinal elements, other features that frequently occur during delirium include disorientation, cognitive deficits, psychomotor agitation or retardation, perceptual disturbances such as hallucinations and illusions, paranoid delusions, and sleep-wake cycle reversal.

DIAGNOSIS

The cornerstone of the evaluation of delirium is a comprehensive history and physical examination (Table 28-2). The first step is to establish the diagnosis of delirium through cognitive assessment and to determine whether the present condition represents an acute change from the patient's baseline cognitive function, such as from a family member. Because cognitive impairment may not be apparent during conversation, brief cognitive screening tests, such as the Short Portable Mental Status Questionnaire (Table 27-4) and the Confusion Assessment Method (CAM), should be used (Video 28-1). Attention should be assessed further with other simple tests, such as a forward digit span (inattention is indicated by an inability to repeat five digits forward) or recitation of the months backward (allow maximum of one error). A delirium assessment specifically for nonverbal (e.g., intubated) patients, called the CAM-ICU, has been developed. The history, which should be obtained from a reliable informant, is targeted to establish the patient's baseline cognitive function and the time course of any mental status change and to obtain clues about potential precipitating factors, such as recent medication changes, intercurrent infection, or medical illness. Physical examination should include a detailed neurologic examination for focal deficits and a careful search for signs of occult infection or an acute abdominal process.

Review of the patient's medication list, including over-the-counter medications and herbal remedies, is crucial, and the use of medications with psychoactive effects should be discontinued or minimized whenever possible.[2] In the elderly, these medications may cause psychoactive effects even at doses and measured drug levels within the "therapeutic range." Consideration should also be given to the possibility that withdrawal from alcohol or other medications is a contributor to delirium.

TABLE 28-2 EVALUATION OF DELIRIUM IN ELDERLY PATIENTS

Perform cognitive testing and determine baseline cognitive functioning: establish the diagnosis of delirium.
Obtain a comprehensive history and perform a physical examination, including a careful neurologic examination for focal deficits and a search for occult infection.
Review the patient's medication list: discontinue or minimize all psychoactive medications; check the side effects of all medications.
Perform a laboratory evaluation (tailored to the individual): complete blood count, electrolytes, blood urea nitrogen, creatinine, glucose, calcium, phosphate, liver enzymes, oxygen saturation.
Search for occult infection: physical examination, urinalysis, chest radiography, selected cultures (as indicated).
When no obvious cause is revealed after these steps, further targeted evaluation is considered in selected patients, as follows: Laboratory tests: magnesium, thyroid function, vitamin B_{12} level, drug levels, toxicology screen, ammonia level Arterial blood gas analysis: indicated in patients with dyspnea, tachypnea, any acute pulmonary process, or history of significant respiratory disease Electrocardiography: indicated in patients with chest or abdominal discomfort, shortness of breath, or cardiac history Cerebrospinal fluid examination: indicated when meningitis or encephalitis is suspected Brain imaging: indicated in patients with new focal neurologic signs or with a history or signs of head trauma Electroencephalography: useful in diagnosis of occult seizure disorder and in differentiating delirium from nonorganic psychiatric disorders

Laboratory Findings

Laboratory evaluation must be tailored to the individual situation (Table 28-2). In patients with preexisting cardiac or respiratory diseases or related symptoms, electrocardiography or arterial blood gas determination may be indicated. The need for cerebrospinal fluid examination is controversial except for the clear indication of the febrile delirious patient, in whom meningitis or encephalitis is suspected. Brain imaging should be reserved for patients with new focal neurologic signs, those with a history or signs of head trauma (e.g., upper body bruising), and those without another identifiable cause of the delirium. Electroencephalography, with a false-negative rate of 17% and a false-positive rate of 22% for distinguishing delirious from nondelirious patients, has a limited role and is most useful for detecting an occult seizure disorder and differentiating delirium from psychiatric disorders.

Differential Diagnosis

A crucial difficulty is distinguishing a long-standing confusional state (dementia) from delirium alone or delirium superimposed on dementia (see Fig. 28-1). These two conditions are differentiated by the acute onset of symptoms in delirium (dementia is much more insidious) and the impaired attention and altered level of consciousness associated with delirium. The differential diagnosis also includes depression and nonorganic psychotic disorders. Although paranoia, hallucinations, and affective changes can occur with delirium, the key features of acute onset, inattention, altered level of consciousness, and global cognitive impairment assist in the recognition of delirium. At times, the differential diagnosis can be difficult, particularly with an uncooperative patient or when an accurate history is unavailable. Because of the potentially life-threatening nature of delirium, it is prudent to manage the patient as if he or she has delirium and to search for and treat underlying precipitants (e.g., intercurrent illness, metabolic derangement, drug toxicity) until further information can be obtained.

TREATMENT Rx

Prevention

The most effective strategy to reduce delirium and its associated complications is primary prevention before delirium occurs. Preventive strategies should address important risk factors and target moderate- to high-risk patients at baseline (Table 28-3). Clinical trials document that multicomponent nonpharmacologic interventions targeted toward delirium risk factors can reduce the incidence of delirium by 30 to 40%.[1] These components typically include strategies designed to improve orientation, to provide therapeutic activities, to increase mobilization and exercise, to enhance sleep with nonpharmacologic interventions, to optimize vision and hearing, and to manage dehydration. Preoperative geriatric consultation and lighter anesthesia also can reduce postoperative delirium. By comparison, no drug treatments, including antipsychotics or cholinesterase inhibitors, have been consistently effective in preventing delirium. Preventive efforts require system-wide changes to educate physicians and nurses, to improve their recognition of delirium and heighten their awareness of its clinical implications, to provide incentives to change practice patterns that lead to delirium (e.g., immobilization, sleep medications, bladder catheters, physical restraints), and to create systems that enhance high-quality geriatric care (e.g., geriatric expertise, case management, clinical pathways, quality monitoring).

Medical Therapy

In general, nonpharmacologic approaches should be used in all delirious patients, and these are usually successful in managing symptoms. Pharmacologic approaches should be reserved for patients whose symptoms may result in the interruption of needed medical therapies (e.g., intubation, intravenous lines) or may endanger the safety of the patient or other persons. No drug is ideal for the treatment of delirium, however; any drug can cloud the patient's mental status further and obscure efforts to monitor the course of the mental status change. The drug should be given at the lowest dose and for the shortest time possible. Neuroleptics are the preferred agents. Haloperidol, the most widely used agent, causes less orthostatic hypotension and fewer anticholinergic side effects than thioridazine and is available in parenteral form; however, it has a higher rate of extrapyramidal side effects and acute dystonias. Second-generation antipsychotics have not proved superior to haloperidol. If parenteral administration is required, intravenous haloperidol should be administered in a monitored setting because its use results in a rapid onset of action, short duration of effect, and risk of hypotension and torsades de pointes; oral and intramuscular administration has a more optimal duration of action, and these are the preferred routes. The recommended starting dose is 0.25 to 0.5 mg of haloperidol orally or intramuscularly, repeated every 30

VIDEO 28-1. Confusion Assessment Method

TABLE 28-3 *NICE* GUIDELINES FOR PREVENTION OF DELIRIUM

CLINICAL FACTOR	RECOMMENDED PREVENTIVE INTERVENTIONS*
Cognitive impairment or disorientation	Provide orienting cues: calendars, clocks, photos. Reorient the patient to time, place, person, schedule. Provide cognitively stimulating activities, like reminiscence. Encourage regular visits from family and friends.
Dehydration or constipation	Encourage patients to drink fluids. Advise team about use of parenteral fluids if necessary. Carefully monitor fluid balance in patients with heart failure or renal disease.
Hypoxia	Assess for symptoms of hypoxia and monitor oxygen saturation levels.
Immobility or limited mobility	Encourage early mobilization and regular ambulation. Keep walking aids (canes, walkers) readily available at all times. Encourage all patients to conduct active range-of-motion exercises.
Infection	Look for and treat infection. Avoid unnecessary catheterization. Implement infection control procedures.
Multiple medications	Review medication for both the type and the number of medications. Monitor for potential interactions.
Pain	Assesses for pain, especially in those who have communication difficulties. Begin and monitor pain management in those with known or suspected pain.
Poor nutrition	Follow general nutrition guidelines and seek input from dietitian early on if needed. Ensure availability and proper fit of dentures.
Sensory impairment	Resolve reversible causes or contributors to impairment. Ensure that working hearing and visual aids are available and used by those who need them. Educate staff.
Sleep disturbance	Avoid medical/nursing procedures during sleep if possible. Schedule medications and procedures to avoid disturbing sleep. Reduce noise level at night unit-wide. Educate staff.

*Operationalized protocols for all recommended preventive interventions are available at www.hospitalelderlifeprogram.org.
Modified with permission from National Institute for Health and Care Excellence (NICE) Clinical Guideline 103. www.nice.org.uk/cg103.

minutes after the vital signs have been rechecked, until sedation has been achieved. The end point should be an awake but manageable patient. The average elderly patient who has not been treated previously with neuroleptics should receive no more than 3 to 5 mg of haloperidol in a 24-hour period. Subsequently, a maintenance dose consisting of half the loading dose should be administered in divided doses during the next 24 hours, with doses tapered during the next few days as the agitation resolves.

Benzodiazepines are not recommended as the first-line treatment of delirium because of their tendency to cause oversedation and to exacerbate the confusional state. They remain the drugs of choice, however, for the treatment of withdrawal syndromes from alcohol and sedative drugs (Chapters 33 and 34).

Nonpharmacologic Management

Multicomponent geriatric interventions may be effective in improving quality of life with the potential for significant cost savings.[1] Nonpharmacologic management techniques recommended for every delirious patient include encouraging the presence of family members, using "sitters" as orienting influences, and transferring a disruptive patient to a private room or closer to the nurses' station for increased supervision. Interpersonal contact and communication, including verbal reorientation strategies, simple instructions and explanations, and frequent eye contact, are vital. Patients should be involved in their own care and allowed to participate in decision making as much as possible. Eyeglasses and hearing aids may reduce sensory deficits. Mobility, self-care, and independence should be encouraged, and physical restraints and bed alarms should be avoided, if possible, because of their tendency to increase agitation, their lack of efficacy, and their potential to cause injury. Attention must be focused on minimizing the disruptive influences of the hospital environment. Clocks and calendars should be provided to assist with orientation. Room and staff changes should be kept to a minimum. A quiet environment with low-level lighting is optimal for delirious patients, and use of ear plugs may be helpful for management of delirium.[A4] Perhaps the most important intervention is to schedule the checking of vital signs, the administration of medications, and the performance of procedures to allow the patient's uninterrupted sleep at night.[3] Nonpharmacologic approaches to relaxation, including music, relaxation tapes, and massage, can be highly effective in managing agitation.

End-of-Life Care

Delirium occurs in at least 80% of patients at the end of life and is considered part of the dying process by many hospice care providers (Chapter 3). Establishing the goals for care in advance with the patient and family is critical to guide appropriate management. For example, some patients may prioritize the preservation of alertness and the ability to communicate with loved ones as long as possible; others may prioritize comfort above all else. Physicians must be aware that even in terminal patients, many causes of delirium are potentially reversible with simple interventions such as adjusting medications, providing oxygen, or treating dehydration; however, aggressive diagnostic evaluation is usually inappropriate in this population. Nonpharmacologic measures to treat agitation and delirium should be instituted in all patients (including massage, music, and relaxation therapies). Haloperidol remains the first-line therapy for delirium in terminally ill patients. If more sedation is indicated, a short-acting benzodiazepine such as lorazepam (starting dose, 0.5 to 1.0 mg PO, IM, or SL), which is easily titrated, is recommended in this setting. Because sedation may result in decreased interaction and communication, increased confusion, and respiratory depression, this choice should be made in conjunction with the family while honoring the patient's preferences.

PROGNOSIS

Delirium increases the risk of death about 2-fold, of institutionalization about 2.5-fold, and of dementia more than 12-fold[4] even after controlling for age, sex, severity of illness, comorbid conditions, and baseline dementia. Delirium also prolongs hospital stays and increases health care costs.

Delirium was previously considered a reversible, transient condition, but symptoms typically last for 30 days or more, only 20% of patients have complete resolution by 6 months, and its detrimental effects may persist at 1 year.[5] Delirium has even more pronounced effects in patients with underlying dementia. The rate of cognitive decline in patients with dementia more than doubles after an episode of delirium,[6] and about one in eight hospitalized patients with dementia who develop delirium will have at least one severe adverse outcome, including a five-fold increased risk of death and a nine-fold increased risk of institutionalization.[7] These studies suggest that strategies to prevent delirium in persons with dementia should be a priority to prevent future cognitive deterioration and adverse outcomes. The long-term detrimental effects are most likely related to the duration, severity, and underlying cause of the delirium and the vulnerability of the patients.

FUTURE DIRECTIONS

Because delirium is common, frequently iatrogenic, and linked to processes of care, it is a marker of the quality of care and safety of the patient in the hospital setting. Research is needed to elucidate the pathophysiologic mechanisms of delirium by the use of neuroimaging modalities, neuropsychological testing, and genetic and laboratory markers; to clarify the contribution of delirium to irreversible cognitive impairment and dementia; and to improve the evidence-based management of delirium.

REVIEW QUESTIONS

1. An 85-year-old woman with a history of hypertension, diabetes, transient ischemic attacks, prior cerebrovascular event without residua, hearing loss, and remote breast cancer is brought in to your office by her daughter for increasing memory lapses. The patient lives alone, but her daughter is nearby and very attentive. What would be the most appropriate next steps in the evaluation?

A. Recent history and urgent brain MRI scan
B. Recent history, cognitive screening, and neurologic examination
C. Recent history, neurologic examination, and brain MRI scan
D. Chest and head CT scans for metastatic disease
E. Recent history, carotid ultrasound, and brain MRI scan

Answer: B The first step is to establish a diagnosis of the memory problem, which requires a history of the mental status change from the daughter, a careful neurologic examination for focal changes, and cognitive screening tests. If the changes are acute, with inattention and cognitive dysfunction on testing, delirium must be excluded. If the changes are chronic with memory impairment on cognitive testing, dementia is more likely. Neuroimaging tests would not be appropriate first steps in the evaluation.

2. You obtain the recent history and conduct cognitive screening of the patient in question 1. The daughter indicates to you that the patient has long-standing short-term memory problems but has been having more difficulty with her regular activities (like forgetting items at the grocery store and getting lost while driving) and has had episodes of disorientation during the past 1 to 2 weeks; at times, she has not made sense on the telephone. On your examination, you find that her neurologic examination is nonfocal, and she makes six errors on the Short Portable Mental Status Questionnaire. She has difficulty in following instructions and gives nonsense answers to some questions. She is disoriented to date, month, and year; she makes five errors on months of the year backwards. What are the key aspects of the history and evaluation that support a diagnosis of delirium?

A. Disorientation, memory loss, and functional impairments (driving, shopping)
B. Disorientation, memory loss, and inattention
C. Acute onset, disorientation, memory loss
D. Acute onset, inattention, and evidence of disorganized thinking
E. Acute onset, inattention, and functional impairments (driving, shopping)

Answer: D The key features of a delirium include the acute onset, inattention (in this case manifested by her difficulty in following instructions and errors on the sustained attention task of months of the year backwards), and evidence of disorganized thinking (in this case manifested by the errors on the mental status questionnaire and her nonsense answers to questions). Acute onset of disorientation and the functional impairments are supportive features but not key diagnostic elements. The memory impairment has been chronic, so it is not helpful diagnostically in this case. Formal cognitive screening is key in establishing the diagnosis of delirium.

3. You are called as the medical consultant to evaluate JS, an 89-year-old retired accountant admitted to the urology service for removal of a benign ureteral tumor, because of a recent history of falling and weight loss. He is ready for discharge, but the family is concerned about his "failure to thrive." He has a history of chronic renal insufficiency, hypertension, intermittent atrial fibrillation, diastolic dysfunction, previous transient ischemic attacks, positive response to PPD, legal blindness due to macular degeneration, osteoarthritis, chronic reflux esophagitis, depression, and mild cognitive impairment. He smokes about three cigars per day and drinks two or three glasses of wine with dinner each evening. His current daily medications include aspirin, famotidine, paroxetine, metoprolol, amiodarone, amlodipine, naproxen, clopidogrel, and a multivitamin with minerals. He takes furosemide about three times a week for ankle edema. His daughter tells you that during the past month, his appetite has been poor in the context of severe heartburn, and he has become increasingly withdrawn and refuses to eat. He has had two falls in the past week and one fall in the hospital last night. In addition, she has found him wandering and disoriented several times during the past week. On your examination, he has temporal wasting and bruised areas on his shoulders, but his neurologic examination is nonfocal. He is disoriented to place, date, day, and year; he makes three errors on serial sevens. He reports seeing butterflies on the bed. He is unable to cooperate with the full mental status testing, stating that he has to get to the bank immediately. What is the *most likely* factor contributing to this patient's delirium?

A. Malnutrition and dehydration
B. Postoperative status
C. Multifactorial etiology
D. Polypharmacy
E. Multimorbidity and depression

Answer: C This is a classic example of delirium resulting from multifactorial etiology in an older person, that is, the complex interplay between baseline, predisposing (vulnerability) factors and precipitating (noxious) factors. Although each of the other answers is likely to be contributing to some degree, the fundamental principle is that delirium is typically of multifactorial etiology in the elderly.

4. You have completed your evaluation of JS (question 3) and made your recommendations to the urologist, including recommendations for a metabolic profile, which reveals a sodium level of 126 mg/dL. The urologist insists that the patient is ready to be discharged and recommends that any further evaluation be completed on an outpatient basis. What are the most appropriate management strategies for the patient at this point?

A. Discharge from the hospital with completion of the evaluation on an outpatient basis by the primary care physician
B. Discharge from the hospital with completion of evaluation on an outpatient basis by the geriatric assessment clinic
C. Keep patient on the urology service and attempt to complete the evaluation and to institute a management plan
D. Obtain a social work consultation for post-acute placement
E. Transfer to the medical service to complete the evaluation and to institute a management plan

Answer: E Because delirium can be a medical emergency, it is important to complete the evaluation in the inpatient setting on a timely basis. Given the expertise needed, this goal may be best achieved on the medical service. The most important next steps are to ensure the patient's safety and to prevent further falls, to evaluate the patient for possible significant head trauma with neuroimaging, to correct hyponatremia and other metabolic derangements, to eliminate or to reduce nonessential psychoactive medications, and to provide appropriate hydration and nutrition. It would not be appropriate at this point to discharge the patient or to transfer him to a post-acute setting.

5. Before JS (case in question 3) was admitted for surgery, what were the *most appropriate* strategies that would have been helpful to prevent delirium?

A. Treatment with oral low-dose haloperidol before, during, and for 3 days after surgery
B. Treatment with oral olanzapine before surgery and sublingual olanzapine after surgery for 48 hours
C. Treatment with donepezil beginning 2 to 4 weeks before surgery and continuing for 1 month postoperatively
D. Multicomponent nonpharmacologic prevention strategies to address orientation, mobility, medications, vision and hearing impairments, nutrition, and hydration
E. Interdisciplinary geriatric consultation beginning on the first postoperative day to address functional and cognitive status

Answer: D To date, there is no grade A evidence that any pharmacologic strategies are effective for preventing delirium. The current recommendation is to use multicomponent nonpharmacologic interventions to address delirium risk factors, such as the Hospital Elder Life Program (HELP) model (which allows fulfillment of all of the NICE guidelines for delirium prevention). Proactive delirium consultation is effective if it is started preoperatively.

29

PRINCIPLES OF DRUG THERAPY

ROBERT B. DIASIO

Under different conditions, a drug may produce diverse effects ranging from no effect to a desirable effect to an undesirable toxic effect. Physicians must learn how to choose the correct drug dosage for different conditions to ensure effective and safe therapy. This necessitates understanding the pharmacokinetics—the movement of a drug over time through the body—and the pharmacodynamics—the relationship between drug concentration and drug effect (Fig. 29-1). This chapter reviews the basic concepts of pharmacokinetics and pharmacodynamics, followed by guidelines on how to use this information to optimize therapeutic applications. Drug interactions and adverse drug responses are briefly discussed, with advice on how both can be recognized and minimized in clinical practice. Lastly, the increasing role of pharmacogenomics in individualizing therapy beyond preventing or predicting adverse drug responses is discussed.

PHARMACOKINETIC PRINCIPLES

Administration

The most efficient and straightforward means of administering a drug into the systemic circulation is by intravenous injection of the drug as a bolus. With this route, the full amount of a drug is delivered to the systemic circulation almost immediately. The same dose also may be administered as an intravenous infusion over a longer period, resulting in a decrease in the peak plasma concentration and an accompanying increase in the time the drug is present in the circulation. Many other routes of administration can be used, including sublingual, oral, transdermal, rectal, inhalational, subcutaneous, and intramuscular; each of these routes carries not only a potential delay in the time it takes the drug to enter the circulation but also the possibility that a large fraction of it will never reach the circulation.

Absorption

Absorption refers to the transfer of a drug from the site of administration to the systemic circulation. Many drugs cross a membrane barrier by passive diffusion and enter the systemic circulation. Because passive diffusion in this setting depends on the concentration of the solute at the membrane surface, the rate of drug absorption is affected by the concentration of free drug at the absorbing surface. Factors that influence the availability of free drug thus affect drug absorption from the administration site; this effect can be exploited to design medications that release a drug slowly into the circulation by prolonging drug absorption. With certain sustained-released oral preparations, the rate of dissolution of the drug in the gastrointestinal tract determines the rate at which the drug is absorbed (e.g., timed-release antihistamines). Similarly, a prolonged drug effect can be obtained by the use of transdermal medications (e.g., nitroglycerin) or intramuscular depot preparations (e.g., benzathine penicillin G).

First-Pass Effect

Some drugs that are administered orally are absorbed relatively efficiently into the portal circulation but are metabolized by the liver before they reach the systemic circulation. Because of this "first-pass" or "presystemic" effect, the oral route may be less suitable than other routes of administration for such drugs. A good example is nitroglycerin, which is well absorbed but efficiently metabolized during the first pass through the liver. However, the same drug can achieve adequate systemic levels when it is given sublingually or transdermally.

Bioavailability

The extent of absorption of a drug into the systemic circulation may be incomplete. The bioavailability of a particular drug is the fraction (F) of the total drug dose that ultimately reaches the systemic circulation from the site of administration. This fraction is calculated by dividing the amount of the drug dose that reaches the circulation from the administration site by the amount of the drug dose that would enter the systemic circulation after direct intravenous injection into the circulation (essentially the total dose). Bioavailability, or F, can range from 0, in which no drug reaches the systemic circulation, to 1.0, in which essentially all of the drug is absorbed. The bioavailability of a drug may vary in different formulations because the overall absorption differs. This variability has become a concern with the increasing use of generic preparations.

Distribution

After delivery of a drug into the systemic circulation either directly by intravenous injection or after absorption, the drug is transported throughout the body, initially to the well-perfused tissues and later to areas that are less perfused. The distribution phase can be assessed best by plotting the drug's plasma concentration on a log scale versus time on a linear scale (Fig. 29-2). For an intravenously administered drug, when absorption is not a factor, the initial phase—from immediately after administration through the rapid fall in concentration—represents the distribution phase, during which a drug rapidly disappears from the circulation and enters the tissues. This is followed by the elimination phase (see later), when drug in the plasma equilibrates with drug in the tissues. During this latter phase, the drug's plasma concentration is thought to be related to drug effect.

Volume of Distribution

The volume of distribution (VD) relates the amount of drug in the body to the concentration of drug in the plasma. It is calculated by dividing the dose that ultimately gets into the systemic circulation by the plasma concentration at time zero (C_{p0}):

$$VD = dose / C_{p0} \quad (1)$$

The C_{p0} can be calculated by extrapolating the elimination phase back to time zero (see Fig. 29-2). The VD is best considered the "apparent VD" because it represents the apparent volume needed to contain the entire amount of the drug, assuming it is distributed throughout the body at the same concentration as in the plasma. Table 29-1 lists pharmacokinetic data for commonly used drugs from several drug classes, showing the wide variation in VD. Digoxin, for example, has a large VD (>5 L), whereas glimepiride has a relatively small VD (0.18 L). As discussed later, VD is a useful pharmacokinetic tool for calculating the loading dose and appreciating how various changes can affect a drug's half-life.

Elimination

Drugs are removed from the body by two major mechanisms: hepatic elimination, in which drugs are metabolized in the liver and excreted through the biliary tract; and renal elimination, in which drugs are removed from the circulation by either glomerular filtration or tubular secretion. For most drugs, the rates of hepatic and renal elimination are proportional to the plasma concentration of the drug. This relationship is often described as a "first-order" process. Two measurements, clearance and half-life, are used to evaluate elimination.

Clearance

The efficiency of elimination can be assessed by quantifying how fast the drug is cleared from the circulation. Drug clearance is a measure of the volume of plasma cleared of drug per unit of time. It is similar to the clinical measurement used to assess renal function—creatinine clearance, which is the volume of plasma from which creatinine is removed per minute. Total drug clearance (Cl_{tot}) is the rate of elimination by all processes (El_{tot}) divided by the plasma concentration of the drug (C_p):

$$Cl_{tot} = El_{tot} / C_p \quad (2)$$

Drugs may be cleared by several organs, but as noted earlier, renal clearance and hepatic clearance are the two major mechanisms. Total drug clearance (Cl_{tot}) can best be described as the sum of clearances by each organ. For most drugs, this is essentially the sum of renal clearance and hepatic clearance:

$$Cl_{tot} = El_{Ren} + Cl_{Hep} \quad (3)$$

Table 29-1 shows the wide variation in clearance values among commonly used medications; some drugs (e.g., phenobarbital) have relatively low clearances (<5 mL/minute), and other drugs (e.g., aspirin) have relatively high clearances (>500 mL/minute). Tobramycin is cleared almost entirely by the kidneys, whereas aspirin, carbamazepine, and phenytoin are cleared less than 5% by the kidneys.

Drug clearance is affected by several factors, including blood flow through the organ of clearance, protein binding to the drug, and activity of the clearance processes in the organs of elimination (e.g., glomerular filtration rate and

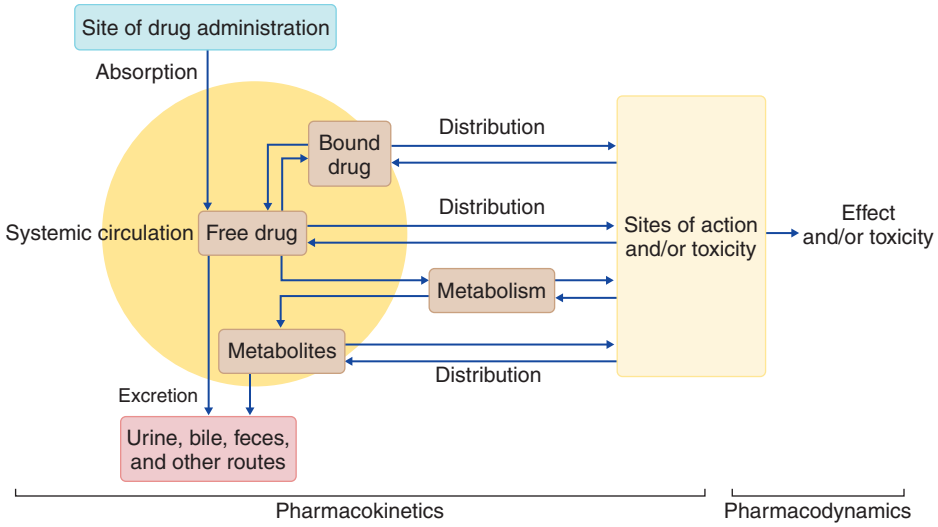

FIGURE 29-1. Schematic of a drug's movement through the body, from the site of administration to production of a drug effect. The relationship between pharmacokinetics and pharmacodynamics is shown.

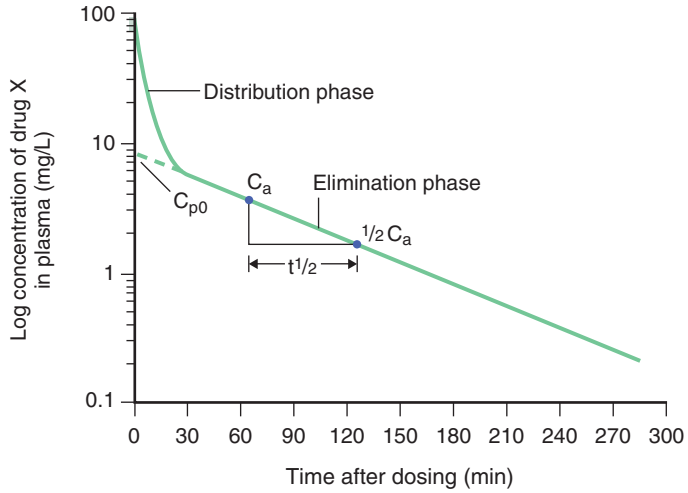

FIGURE 29-2. Representative drug concentration versus time plot used in pharmacokinetic studies. Concentration of drug is plotted with a logarithmic scale on the ordinate, and time is plotted with a linear scale on the abscissa. The resultant curve has two phases: the distribution phase, which is the initial portion of the plotted line when the concentration of drug decreases rapidly; and the later elimination phase, during which there is an exponential disappearance of drug from the plasma over time. The *dotted line* extrapolated from the elimination phase back to time zero is used to calculate plasma concentration at time zero (C_{p0}). During the elimination phase, the half-life (t½) can be calculated as the time it takes to decrease the concentration by half (shown here as the time needed to decrease from concentration C_a to ½ C_a).

tubular secretion in the kidney, enzyme activity in the liver). Drug clearance is not affected by the distribution of drug throughout the body (VD) because clearance mechanisms act only on drug in the circulation.

Half-Life

The amount of time needed to eliminate a drug from the body depends on the clearance and the VD. The first-order elimination constant (K_e) represents the proportion of the apparent VD that is cleared of drug per unit of time during the drug's exponential disappearance from the plasma over time (elimination phase):

$$K_e = \mathrm{Cl}/\mathrm{VD} \qquad (4)$$

The value of this constant for a particular drug can be determined by plotting drug concentration versus time on a log-linear plot (see Fig. 29-2) and measuring the slope of the straight line obtained during the exponential (elimination) phase.

The time needed to eliminate the drug is best described by its half-life ($t_{1/2}$), which is the time required during the elimination phase (see Fig. 29-2) for the plasma concentration of the drug to be decreased by half. Mathematically, the half-life is equal to the natural logarithm of 2 (representing a reduction of drug concentration to half) divided by K_e. Substituting for K_e from Equation 4 and calculating the natural logarithm of 2, the half-life can be represented by the following equation:

$$t_{1/2} = 0.693\ \mathrm{VD}/\mathrm{Cl} \qquad (5)$$

From this equation, one can predict that at a given clearance, as the VD increases, the half-life increases. Similarly, at a given VD, as the clearance increases, the half-life decreases. Clinically, many disease states (see later) can affect VD and clearance. Because disease affects VD and clearance differently, the half-life may increase, decrease, or not change much at all. Therefore, the half-life by itself is not a good indicator of the extent of abnormality in elimination.

The half-life is useful to predict how long it takes for a drug to be eliminated from the body. For any drug that has a first-order elimination, one would expect that by the end of the first half-life, the drug would be reduced to 50%; by the end of the second half-life, to 25%; by the end of the third half-life, to 12.5%; by the end of the fourth half-life, to 6.25%; and by the end of the fifth half-life, to 3.125%. In general, a drug can be considered essentially eliminated after three to five half-lives, when less than 10% of the effective concentration remains. Table 29-1 shows the wide variation in half-life for several commonly used drugs.

CLINICAL APPLICATION OF PHARMACOKINETIC PRINCIPLES

Using a Loading Dose

To attain a desired therapeutic concentration rapidly, a loading dose is often used. In determining the amount of drug to be given, the clinician must consider the "volume" within the body into which the drug will be distributed. This volume is best described by the apparent VD. The loading dose can be calculated by multiplying the desired concentration by the VD:

$$\text{Loading dose} = \text{desired concentration} \times \mathrm{VD} \qquad (6)$$

Rapid administration of the entire loading dose may produce an initially high peak concentration that results in toxicity. This problem can be avoided either by administering the loading dose as a divided dose or by varying the rate of access to the circulation, such as by administering the drug as an infusion (with an intravenous drug) or by taking advantage of the slower access to the circulation from various other routes (e.g., oral dosing). This approach is illustrated by phenytoin (see Table 29-1), which may need to be administered with a loading dose to achieve a therapeutic level (10 to 20 mg/L) rapidly. Because the VD for phenytoin is approximately 0.6 L/kg, the loading dose calculated from Equation 6 is 420 mg/L to attain a minimally

TABLE 29-1 PHARMACOKINETIC PARAMETERS FOR SOME COMMONLY USED DRUGS

DRUG	VD (L/kg)	PROTEIN BINDING (%)	TOTAL CLEARANCE (mL/min)	% OF TOTAL CLEARANCE AS RENAL CLEARANCE	HALF-LIFE (hr)	THERAPEUTIC RANGE (mg/L)
Amoxicillin	0.47	17-18		86	1.2	2-8
Aspirin (acetylsalicylic acid)	0.14-0.18	80-90	575-725	<2	0.2-0.3	20-250
Carbamazepine	1.2	75-90	50-125	1-3	12-17	4-12
Digoxin	5-7.3	20-30	75	50-70	34-44	0.5-2
Glimepiride	0.18	>99.5	0.62 ± 0.26	<0.5	3.4 ± 2.0	
Lidocaine	3	60-80	700	<10	1.5-2	1-5
Lithium carbonate	0.7-1	0	20-40	95-99	20-270	0.4-1.4*
Penicillin G	0.5-0.7	45-68	—	20	0.4-0.9	Variable
Phenobarbital	0.6-0.7	20-45	4	25	2-6 days	<10-40*
Phenytoin	0.4-0.8	88-93	—	<5	7-26	10-20
Procainamide	2.2	14-23	470-600	40-70	2.5-4.7	4-8
Theophylline	0.3-0.7	60	36-50	<10	4-16	5-20
Tobramycin	0.25-0.30	<10	70	>95	2-4	0.5-2 (TR) 4-8 (PK)
Vancomycin	0.4-1	52-60	65	85	4-6	5-10 (TR) 25-35 (PK)

*Therapeutic range varies according to the indication for the drug. For example, lithium carbonate in the range of 0.4-1.3 mg/L is appropriate for affective schizophrenia disorder; a range of 1.0-1.4 mg/L is appropriate for mania. Phenobarbital concentration below 10 mg/mL is appropriate for anticonvulsant therapy; 40 mg/L is appropriate as a hypnotic.
PK = peak value; TR = trough value; VD = volume of distribution.

therapeutic level of 10 mg/L in a 70-kg adult. However, administration of 420 mg of phenytoin by intravenous bolus carries the risk for cardiac arrest and death. By taking advantage of the reduced bioavailability (F = 0.8) and slow absorption of oral phenytoin, the loading dose can be administered safely as an oral dose of 500 mg.

The equation for the loading dose can also be used to calculate the dose needed to "boost" an inadequate blood level of drug to a desired therapeutic range. If therapeutic monitoring (see later under Drug Monitoring as a Guide to Therapy) shows that the phenytoin level is 5 mg/L and the desired level is 15 mg/L, it is necessary to multiply the difference needed to achieve the desired concentration (10 mg/L) by the VD (0.6 L/kg) to determine the dose (in mg/kg) necessary to achieve this drug level after distribution. In a 70-kg individual, 0.6 mg/kg is multiplied by 70 kg to obtain the calculated loading dose (420 mg) that can be administered safely. A 500-mg oral dose with a bioavailability of less than 1 (e.g., F = 0.8) would deliver to the systemic circulation the approximate amount needed and avoid the risks associated with rapid intravenous administration.

Determining Drug Accumulation

Continuing to administer a drug, either as a prolonged infusion or as repeated doses, results in accumulation until a steady state occurs. Steady state is the point at which the amount of drug being administered equals the amount being eliminated so that the plasma and tissue levels remain constant. The elimination half-life determines not only the time course of drug elimination but also the time course of drug accumulation. This mirror-image pattern of drug accumulation and elimination is illustrated in Figure 29-3. As with drug elimination, three to five half-lives determine the time it takes to reach steady state during drug accumulation. Whereas drugs with short half-lives accumulate rapidly, drugs with long half-lives require a longer time to accumulate, with a potential delay in achieving therapeutic levels. For drugs with long half-lives, a loading dose may be needed to obtain rapid drug accumulation and a more rapid therapeutic effect.

With each change in drug dose or rate of infusion, a change in steady state occurs. Although it is not obvious for drugs with short half-lives, the effects of dose adjustments for drugs with longer half-lives are delayed, and the time varies directly with the drug's half-life.

Using a Maintenance Dose

After steady state is reached in three to five half-lives with either a continuous infusion or intermittent doses, the rate of drug administered equals the rate of drug eliminated. For an intravenous drug, the administration rate is the infusion rate (I); for a drug administered by another route (e.g., orally), the administration rate is the dose per unit of time (D/t). Equation 7 shows

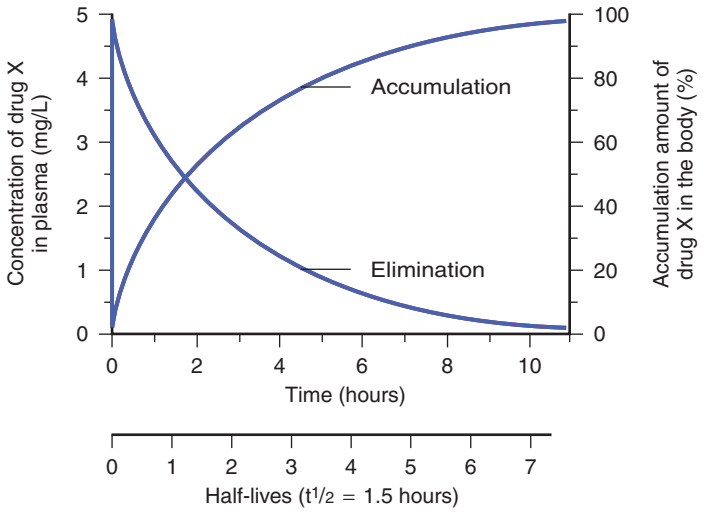

FIGURE 29-3. Representative plot of the mirror-image relationship between the elimination of drug (after drug is discontinued) and the accumulation of drug (during infusion). The plot shows the concentration on the left *y*-axis and time on the upper *x*-axis. The lower *x*-axis shows the time in half-lives, and the *y*-axis on the right shows the percentage of drug in the body. After three to five half-lives, elimination is essentially complete, and accumulation is essentially at a steady state.

that the rate of elimination (total) equals $Cl_{tot} \times C_p$. With an intravenously administered drug, because the infusion rate equals the elimination rate at steady state, it follows that

$$I = Cl_{tot} \times C_p \quad (7)$$

Similarly, with an orally administered drug, the dose administered per unit of time equals the elimination rate at steady state, with the result that

$$D/t = Cl_{tot} \times C_p \quad (8)$$

These equations show the direct relationship between the dose and the resultant plasma concentration at steady state. This relationship is independent of the distribution of the drug. By use of these equations, it is possible to determine the infusion rate or the interval and dose needed to achieve and maintain a specified drug concentration in the plasma.

When a drug is administered intermittently, it approaches steady-state concentration over time, with a pattern similar to that observed with continuous infusion (Fig. 29-4). With intermittent drug administration, such as with an

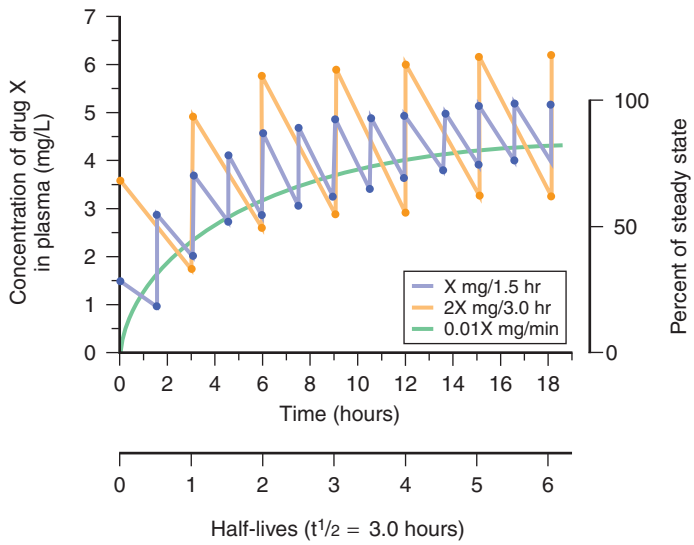

FIGURE 29-4. Accumulation of drug over time, approaching a steady state. Time is depicted in hours (upper *x*-axis) and half-lives (lower *x*-axis, showing that steady state is reached in three to five half-lives). The *green line* depicts the pattern produced by an infusion of a hypothetical drug at a dose of 0.01X. The *orange line* shows the pattern resulting from oral administration of a 2X dose every 3 hours, and the *blue line* represents the pattern produced by oral administration of dose X every 1.5 hours.

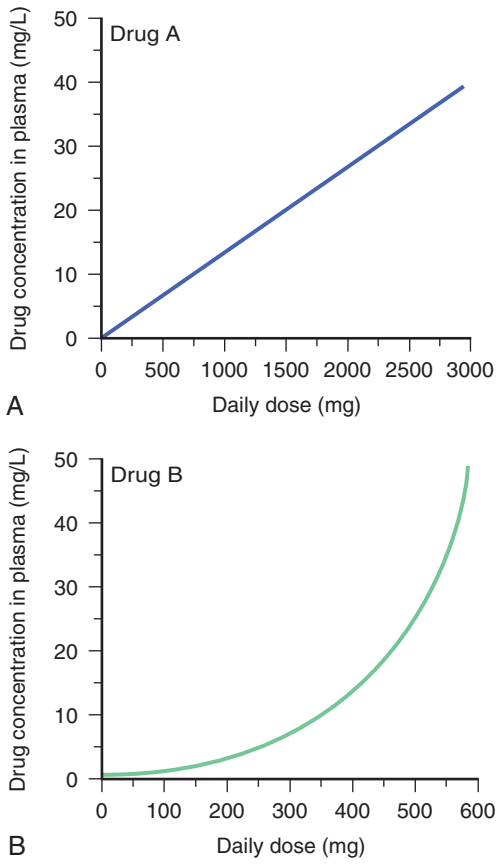

FIGURE 29-5. Effect of increasing the dose of a drug on its serum concentration. A, Drug A follows first-order or linear kinetics. B, Drug B follows zero-order or nonlinear (or saturable) kinetics.

oral dose, the drug concentration fluctuates; the magnitude of fluctuation between the peak and trough concentrations depends on the interval of administration, drug half-life, absorption characteristics, and site of administration. The effect of a change in the interval of administration for an oral drug is shown in Figure 29-4. As the intervals decrease below the half-life, the fluctuation decreases and approaches the curve produced by an intravenous infusion. Orally administered drugs may reach the blood stream more rapidly, attaining a higher peak concentration with one formulation, whereas the same drug administered as a timed-release formulation is absorbed more slowly, with a lower peak concentration but lasting longer in the plasma. Finally, the same drug administered by different routes may have different plasma profiles not only because of differing absorption characteristics but also because of other effects, such as first-pass metabolism.

Decreasing the Drug Level

At times, it may be necessary to decrease the plasma drug level while maintaining therapy (e.g., when signs of toxicity become apparent or a potentially dangerously high concentration of drug is noted; see later). The most effective and rapid response is to discontinue the drug; the length of time for which the drug is discontinued is determined by the estimated half-life of the drug in the specific patient. After discontinuation of the drug for a time based on its half-life, the total clearance (Cl_{tot}) of the drug can be used to determine what infusion rate (I, Equation 7) or dose and interval (D/t, Equation 8) must be used to achieve the new desired concentration (C_p).

Effect of Dose Increases on Elimination Kinetics

Although the previously discussed pharmacokinetic principles can be a guide to the dose of most drugs, not all drugs behave the same when the dose is increased. The elimination of most drugs follows first-order or linear kinetics; the amount of drug eliminated is directly proportional to the concentration of drug in the plasma (Fig. 29-5A). A few drugs have a different pattern of elimination. Three of the most commonly used drugs that exhibit this different pharmacokinetic pattern are ethanol, phenytoin, and salicylate. These drugs have dose-dependent, nonlinear saturation kinetics. As the dose of drug increases and the concentration of drug in the plasma rises, the relative amount of drug being eliminated falls (i.e., the clearance decreases) until the rate of drug metabolism is at its maximum. At this point, drug elimination is said to be zero order, and the drug concentration in plasma starts to increase much more (no longer linearly) with each subsequent increase in dose (Fig. 29-5B).

DRUG MONITORING AS A GUIDE TO THERAPY

Although published pharmacokinetic data (usually population averages) such as those in Table 29-1 are useful to determine initial drug dosing, modification of the dose may be needed in an individual patient. For some drugs (e.g., certain antihypertensives or anticoagulants), the therapeutic effects (e.g., blood pressure or coagulation) can be quantified easily over a range of concentrations, permitting adequate drug adjustment. For many other drugs (e.g., some antiarrhythmics or antiseizure medications), therapeutic effects over a range of concentrations are not readily detectable. With these drugs, the plasma concentration may provide further guidance in optimizing therapy if the plasma concentration of the drug is a reflection of its concentration at the site of action and the drug effects are reversible. A third, much smaller group of drugs produces irreversible effects (e.g., aspirin inhibition of platelet aggregation). With these drugs, plasma drug concentration does not correlate with drug effect, and drug monitoring is not useful.

To use drug concentration as a guide to therapy, it is necessary to establish a range of concentrations from minimally to maximally efficacious with tolerable toxicity. This range of concentrations, or the *therapeutic window*, is usually determined from a dose-response curve generated from a population of patients who have been examined closely for therapeutic and toxic effects (Fig. 29-6). This graph also may be used to determine the *therapeutic index*, a useful measure of drug toxicity calculated by dividing the 50% value from the toxicity curve by the 50% value from the efficacy curve. Because these curves are generated from population data, the values may not be applicable to all individuals.

Table 29-1, in addition to providing useful pharmacokinetic data, lists therapeutic ranges of several common drugs for which measuring the concentration and knowing the therapeutic range may be useful in clinical management. Many of these drugs are used to treat serious or life-threatening diseases. In these cases, it is essential to avoid inadequate doses because a therapeutic effect is often critical. Excessive doses must also be avoided because of the risk for toxicity with drugs that have a small therapeutic index. In contrast, it is not necessary to assay levels of drugs used to treat noncritical diseases (when inadequate treatment is not a serious problem) or for which the therapeutic index is large (when relative overtreatment is not likely to produce toxicity).

Problems with Interpreting Drug Concentration

The time of blood collection, perhaps more than any other factor, contributes to the misinterpretation of drug levels. As can be seen in Figure 29-2, if

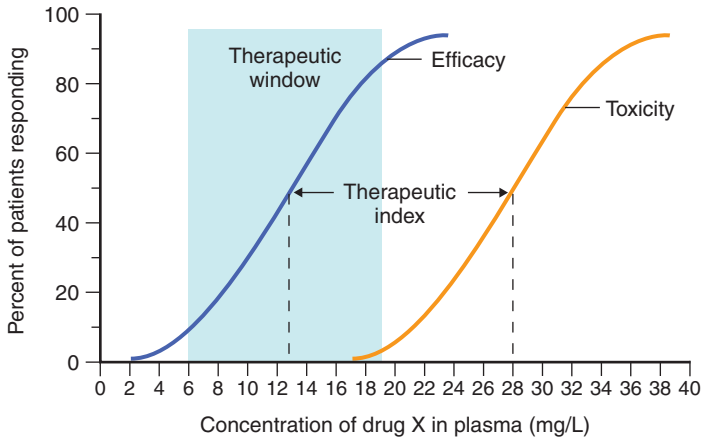

FIGURE 29-6. Pattern produced in a dose-response population study in which both effect and toxicity are measured. The therapeutic window is shown as the range of therapeutically effective concentrations, which includes most of the efficacy curve and less than 10% of the toxicity curve. The therapeutic index is calculated by dividing the 50% value on the toxicity curve by the 50% value on the efficacy curve.

sampling is performed too early, while the drug is still in the distribution phase, the drug level may be high and not reflect drug concentration at the site of action. It is therefore important to sample after the distribution phase.

For many drugs administered intermittently, a trough level, obtained immediately before the next dose is administered, is most useful for making decisions about dose adjustments (see Table 29-1). For drugs administered by infusion or intermittently at short intervals (see Fig. 29-4), the best time to draw blood is during steady state.

Protein binding is another major factor that contributes to the misinterpretation of drug levels. Free drug (not bound to protein and able to equilibrate with tissues and to interact with the site of action) is the critical drug concentration when therapeutic decisions are being made. Many drugs are tightly bound to plasma protein, however. Table 29-1 shows that many commonly used drugs, such as aspirin, carbamazepine, phenytoin, and glimepiride, have protein binding of more than 75%. Because many of the commonly used drug assays determine total drug concentration (which includes protein-bound drug and free drug), assessment of the "true" free drug concentration may be inaccurate, particularly if the fraction of drug bound to protein varies. In addition, the drug's binding may be decreased by disease or by other drugs, leading to increased unbound drug levels that alter the interpretation of the measured drug concentrations. Kidney and liver disease can change the binding of certain drugs (e.g., phenytoin) to protein because of a decrease in protein (e.g., decreased albumin, as in nephrotic syndrome or liver disease) or as a result of competition for protein binding by endogenously produced substances (e.g., uremia in kidney disease, hyperbilirubinemia in liver disease). Similarly, other drugs being administered may compete for binding to protein. A major problem secondary to these changes in protein binding is that free drug is not typically measured in many of the common drug assays used by clinical laboratories. Lastly, changes in drug binding to protein can affect the pharmacokinetics of the drug, the main effect being on the VD, which increases as protein binding decreases.

The usefulness of a drug assay is also limited by physiologic changes that may alter the response at a particular drug concentration. An example of this pharmacodynamic change is the response produced by a certain level of digoxin in the presence of altered electrolyte concentrations (e.g., potassium, calcium, and/or magnesium). Tolerance, a reduced response to a given concentration of drug with continued use, is another pharmacodynamic change that may alter how a drug concentration is interpreted. Tolerance is commonly observed with the continued use of narcotics (e.g., in terminal cancer patients); initially, adequate pain control is noted at a given drug concentration, but after long-term administration, the same drug concentration is no longer associated with pain relief.

ADJUSTMENTS OF DRUG DOSE WITH DISEASE

Kidney Disease

The major questions to be answered when determining whether a drug dosage needs to be adjusted in the setting of kidney disease are the following: Is the drug primarily excreted through the kidneys? Are increased drug levels likely to be associated with toxicity? If the answer to both is yes, it is likely that with decreased renal clearance, a drug will accumulate and become toxic. With renal failure, it is necessary to adjust the dosing regimen of such drugs, particularly for a drug with a long half-life and a small therapeutic index (e.g., digoxin).

To obtain the desired concentration over time in the presence of decreased clearance, adjustments can be made by decreasing the dose while maintaining the dose interval (DD), maintaining the dose but increasing the interval between doses (II), or a combination of both (DD and II). Table 29-2 shows how these three different methods are used to adjust the dosages of several common drugs to account for renal dysfunction (see Table 29-1 for their pharmacokinetic properties with normal renal function). With these adjustments, it may be possible to achieve an average concentration similar to that obtained with normal renal function; however, there may be concomitant marked changes in the magnitude of peak and trough values. In choosing the type of drug adjustment, the clinician should consider not only the therapeutic index of the drug but also (1) whether an effective concentration must be achieved quickly and maintained within a narrow range (i.e., maintaining an average drug concentration and avoiding trough levels at which the drug is ineffective) and (2) whether toxicity is associated with elevated (i.e., peak) drug concentrations.

Renal drug clearance correlates with creatinine clearance (whether the drug uses glomerular filtration or tubular secretion); therefore, any adjustment of drug dose in kidney disease can use the creatinine clearance to calculate the dose needed because renal drug clearance is proportional to creatinine clearance. The creatinine clearance (Cl_{cr}), which is used as an estimate of glomerular filtration rate, may be calculated directly from the serum creatinine concentration by the following equation:

$$Cl_{cr} = [(140 - age) \times weight\,(kg)]/[72 \times serum\ creatinine\,(mg/dL)] \quad (9)$$

The calculated creatinine clearance should be multiplied by 0.85 for females. (*Note:* This calculation applies only when the serum creatinine concentration is less than 5 mg/dL and renal function is not rapidly changing.)

Using Clearance for Dose Adjustment

The dose of a drug used in renal insufficiency ($dose_{D\text{-}RI}$) is proportional to the dose used with normal renal function ($dose_D$) in the same ratio as clearance of the drug in renal insufficiency ($Cl_{D\text{-}RI}$) to clearance with normal renal function (Cl_D). By rearranging, $dose_{D\text{-}RI}$ is defined as:

$$Dose_{D\text{-}RI} = dose_D \times [Cl_{D\text{-}RI}/Cl_D] \quad (10)$$

One can estimate the $Cl_{D\text{-}RI}$ by multiplying Cl_D by the ratio of the creatinine clearance in renal insufficiency ($Cl_{cr\text{-}RI}$) over Cl_{cr} with normal renal function:

$$Cl_{D\text{-}RI} = Cl_D \times [Cl_{cr\text{-}RI}/Cl_{cr}] \quad (11)$$

As shown in Equation 3, total clearance is the sum of clearance by renal and nonrenal (typically hepatic) mechanisms. Any nonrenal clearance is assumed to remain normal, and only the renal clearance is adjusted, with total clearance being reduced only to the extent that renal clearance is reduced. The dose may be calculated from the total (adjusted) clearance and the desired plasma concentration by either Equation 7 or Equation 8. The calculated dose is only an initial guide to the dose needed, however. By monitoring the drug response or the plasma drug concentration at various times after initial dosing, further dose adjustments can be made as necessary. From a practical perspective, most clinical dose adjustments in the presence of renal dysfunction can be guided by published tables based on changes in glomerular filtration rate (see Table 29-2) and the effectiveness of dialysis in removing the drug. Computerized decision support systems are particularly effective in guiding medication dosing for inpatients with renal insufficiency.

Loading Dose in Renal Insufficiency

For drugs typically administered with a loading dose in patients with normal renal function, the same approach can be used in those with renal insufficiency to ensure that the desired concentration is achieved rapidly. For drugs typically administered without a loading dose, the presence of a prolonged half-life resulting from renal insufficiency may delay drug accumulation to steady state. In this setting, a loading dose (equal to the amount needed to reach steady state with normal renal function) is required.

Additional Considerations in Renal Insufficiency

Because of individual differences among patients, the approaches outlined earlier should be considered only initial approximations to prevent ineffective

TABLE 29-2 ADJUSTMENT OF DRUG DOSAGE IN RENAL FAILURE

DRUG	Type of Elimination	HALF-LIFE (hr)		METHOD*	ADJUSTMENT FOR RENAL FAILURE			
		Normal	End-Stage Renal Disease		GFR > 50 mL/min	GFR 10-50 mL/min	GFR < 10 mL/min	Removed by Dialysis†
Amikacin	Renal	2-3	30	DD II	60-90% 12 hr	30-70% 12-18 hr	20-30% 24 hr	Yes
Aspirin	Hepatic (renal)	2-19	Unchanged	II	4 hr	4-6 hr	Avoid	Yes
Carbamazepine	Hepatic (renal)	35	?	DD	Unchanged	Unchanged	75%	No
Digoxin	Renal (nonrenal 15-40%)	36-44	80-120	DD II	Unchanged 24 hr	25-75% 36 hr	10-25% 48 hr	No
Lidocaine	Hepatic (renal < 20%)	1.2-2.2	1.3-3	DD	Unchanged	Unchanged	Unchanged	No
Lithium carbonate	Renal	14-28	Prolonged	DD	Unchanged	50-75%	25-50%	Yes

Vancomycin	Renal	6-8	200-250	II	24-72 hr	72-240 hr	240 hr	No

*DD (alone) = decrease dose (maintain same interval); II (alone) = increase interval between doses (maintain dose); DD and II (together) = combination of both approaches.
†Dialysis refers to hemodialysis.
GFR = glomerular filtration rate.

(too low) or toxic (too high) doses. For maintenance therapy, it is desirable to monitor blood levels to guide dosing.

If a metabolite of the drug is responsible for its effect or toxicity and the metabolite accumulates in the setting of renal failure, the drug level alone may not provide sufficient guidance for planning therapy. For example, the major metabolite of procainamide is *N*-acetylprocainamide, which has a toxicity similar to that of the parent drug but only modest antiarrhythmic activity. In the setting of renal failure, *N*-acetylprocainamide may accumulate dramatically because it is more dependent on renal elimination. Measurement of procainamide levels alone does not accurately assess either the levels needed for antiarrhythmic effect or the risk for toxicity.

Liver Disease

Although many drugs are biotransformed in the liver, it is not possible to make any general recommendations for drug dose adjustments in liver disease. In contrast to renal disease, no useful laboratory test is available on which to base dose adjustments. It has been suggested that if the liver's capacity to produce protein (reflected by albumin concentration and prothrombin time) is reduced significantly, the clearance of drugs metabolized by the cytochrome P-450 enzymes is probably reduced as well.

One special situation that can develop with chronic liver disease and may require dose adjustment is the portacaval shunt. This condition produces not only a potential hemodynamic alteration, leading to decreased hepatic blood flow and accompanying decreased clearance, but also a possible bypassing of the first-pass effect, resulting in higher concentrations of drug reaching the systemic circulation. Drugs with a large hepatic extraction that are typically administered orally (e.g., propranolol) may appear in the systemic circulation at higher, potentially toxic concentrations.

Hemodynamic Diseases

Decreased cardiac output and hypotensive conditions lead to decreased perfusion of the organs, including those responsible for eliminating drugs. As noted earlier with regard to primary kidney disease, the dose can be adjusted for decreased renal perfusion by the use of creatinine clearance. The effect of decreased hepatic blood flow on pharmacokinetics is more difficult to assess. For drugs that have a high hepatic extraction (e.g., lidocaine), decreased hepatic blood flow suggests a need for dose reduction.

Altered hemodynamics also may affect the distribution of selected drugs. Drugs that have a relatively large VD (e.g., lidocaine, procainamide, quinidine) may be affected by conditions leading to hypotension, such as shock, resulting in a decrease in the apparent VD. With a reduced VD, the loading dose of a drug should be reduced to avoid potentially toxic drug levels.

In general, in the setting of severely compromised hemodynamics, it is advisable to be conservative, avoiding potentially toxic loading and maintenance doses of drugs. Drug levels and the clinical status should be monitored closely, and drug doses should be adjusted as necessary.

APPROACH TO DRUG OVERDOSE

The pharmacokinetic principles discussed earlier can be used to determine the best approach to drug removal in the setting of a drug overdose, particularly if hemodialysis or hemoperfusion is contemplated. The major goal is to increase the overall clearance of the drug, removing a substantial fraction of the total body load of drug. Examination of the VD and clearance values can provide some guidance. For drugs with a large VD (e.g., digoxin; see Table 29-1), only a small amount can be removed because clearance affects only the amount of drug present in the plasma, and a large portion of the drug is outside the plasma compartment. Similarly, for drugs with high clearance values, hemoperfusion may increase the overall clearance only minimally and is not indicated. Table 29-2 provides data for determining whether hemodialysis is likely to be useful to remove several commonly prescribed drugs.

DRUG USE IN ELDERLY PATIENTS

Administering drugs to elderly patients is perhaps the most challenging area of adult therapeutics because of several factors: the increasing likelihood of multiple illnesses, often with multisystemic involvement; the need for these patients to take multiple drugs (often prescribed by different physicians); and the increasing probability of altered pharmacokinetics and pharmacodynamics. These factors together contribute to a significantly increased frequency of drug interactions and adverse drug responses in this group of patients.

Pharmacokinetic Changes with Age

These changes can be secondary to the general physiologic effects of aging, such as alteration in body composition, or to specific changes in pharmacokinetically important organs (e.g., kidneys, liver). The distribution of drugs

tends to change dramatically with age, mainly because of changes in body composition. Most typical is the increase in total body fat, with the accompanying decrease in lean body mass and total body water. The concentration of plasma proteins may also change; in particular, albumin decreases as the liver ages. Changes in drug distribution are manifested as a change in the apparent VD. For water-soluble drugs that are not bound to plasma proteins, the apparent VD is reduced; in contrast, for lipid-soluble drugs, the VD is increased. Minimal changes in metabolism accompany aging, but these alone cannot account for altered pharmacokinetics.

Excretion can be altered in the elderly, and the clearance of many drugs is decreased. Cardiac output and blood flow to the kidneys and liver also may be decreased. Glomerular filtration rate may be reduced by 50%. Hepatic elimination of drugs is less affected, except for drugs with a high hepatic clearance (e.g., lidocaine). The elimination half-life of many drugs is increased with aging as a consequence of a larger apparent VD and a decreased hepatic or renal clearance (see Equation 5).

Pharmacodynamic Changes with Age

These changes are a result of changes in the responsiveness of the target organ. They require the use of smaller drug doses in elderly patients, even if the pharmacokinetics are unchanged. This affects many drugs commonly used in elderly people; for example, antianxiety drugs and drugs from the sedative-hypnotic class may produce increased central nervous system depression in elderly patients at concentrations that are well tolerated in younger adults. Similarly, anticoagulants (e.g., warfarin) may produce hemorrhage in elderly people at concentrations that are well tolerated in younger adults.

General Recommendations for Drug Use in Elderly Patients

- Clearance of drugs eliminated by the kidneys may be reduced by 50%.
- Drugs eliminated primarily by the liver typically do not require dose adjustments for age, except for drugs with high hepatic clearances, which may be affected by the age-related decrease in hepatic blood flow.
- Because of the potential for increased target organ sensitivity in elderly people, only the lowest effective dose should be used.
- Frequent reviews of the patient's drug history should be conducted, including both prescription and over-the-counter medications, keeping in mind the increased potential risk for drug interactions and adverse drug responses.

INTERACTIONS BETWEEN DRUGS

Because patients are typically treated with multiple agents, even for a single disease, the possibilities for drug interactions are great. Many clinically important drug interactions typically involve a drug with a low therapeutic index (e.g., warfarin) and an easily detectable pharmacologic effect (e.g., bleeding), such that a small increase in the amount of drug produces a significant effect (toxicity).

It is difficult to accurately assess the prevalence of drug interactions in either the inpatient or the ambulatory setting, particularly because no formal and comprehensive surveillance mechanism is available. The risk for drug interactions seems to be increasing, particularly for critically ill, hospitalized patients, who are frequently taking more than 10 medications.[1]

There are basically two types of drug interaction: (1) pharmacokinetic drug interactions, caused by a change in the amount of drug or active metabolite at the site of action; and (2) pharmacodynamic drug interactions (without a change in pharmacokinetics), caused by a change in drug effect.

Pharmacokinetic Drug Interactions

Less Drug at the Site of Action

Decreased Absorption

The gastrointestinal lumen is perhaps the best example of an area where drug interactions can result in decreased drug absorption. Some commonly used drugs can illustrate this type of interaction. For many drugs, a physicochemical interaction prevents the drug from being absorbed. Drugs such as colestipol and cholestyramine (resins used to lower cholesterol and bind bile acids) can also bind other drugs present in the gastrointestinal lumen, including digoxin and warfarin. Because of the potential for many other drugs to be bound, it is generally recommended that other drugs not be administered within 2 hours of colestipol or cholestyramine. Another type of interaction occurs when metal ions (e.g., aluminum, calcium, and magnesium in antacids and iron in supplements to treat iron deficiency) form insoluble complexes with tetracyclines, which can act as chelating agents. Other commonly used medications that decrease absorption include kaolin-pectin suspensions to treat diarrhea. These medications can significantly inhibit the absorption of coadministered drugs (e.g., digoxin).

Drugs that are particularly susceptible to pH changes may have decreased absorption when they are administered with other drugs that either affect gastric acidity or alter the extent of exposure to low pH. Protein pump inhibitors or histamine-2 receptor antagonists may elevate gastric pH, which can inhibit the dissolution and subsequent absorption of drugs that are weak bases (e.g., ketoconazole). Medications that delay gastric emptying (e.g., belladonna alkaloids) can increase the degradation of a coadministered acid-labile drug (e.g., levodopa), resulting in decreased absorption.

Altered Distribution

Drugs that use the same active transport process to reach their site of action can compete at the level of transport, resulting in lower levels of drug reaching that site. The classic example of this type of interaction is the coadministration of guanidinium-type antihypertensives with tricyclic antidepressants, phenothiazines, and certain sympathomimetic amines (e.g., ephedrine), which block the effects of the antihypertensive drug.

Increased Metabolism

Many drugs (e.g., phenobarbital, phenytoin, ethanol, glutethimide, griseofulvin, rifampin) and toxic compounds (e.g., cigarette smoke, certain chlorinated hydrocarbons) can increase the hepatic metabolism of other drugs (e.g., corticosteroids, cyclophosphamide, cyclosporine, certain β-adrenergic blockers, theophylline, warfarin) by inducing the activity of the cytochrome P-450 super family of monooxygenase enzyme.

More Drug at the Site of Action

Increased Absorption

Any drug that increases the rate of gastric emptying (e.g., metoclopramide) can potentially increase the absorption of acid-unstable drugs. Also, drugs that decrease intestinal motility (e.g., anticholinergics) may increase the absorption of drugs that are relatively poorly absorbed (e.g., digoxin tablets) by increasing the drug's contact time with the absorbing surface.

Altered Distribution

Drugs bound to protein are limited in their distribution (particularly to the site of action) and are not available for metabolism or excretion. Drugs can compete with each other for binding to plasma proteins, resulting in drug interactions. Sulfonamides can displace barbiturates bound to serum albumin, leading to increased levels of free barbiturates and possible toxicity.

Decreased Metabolism

One of the most impressive drug interactions is produced when one drug inhibits the metabolism of another, leading to the second drug's accumulation and a significant risk for toxicity. This type of interaction results when 6-mercaptopurine, an antileukemic drug with a low therapeutic index, is used with allopurinol, often administered to control hyperuricemia. The interaction may result in potentially life-threatening toxicity.

Some drugs can inhibit the metabolism of many other drugs. For example, cimetidine can inhibit the metabolism of diazepam, imipramine, lidocaine, propranolol, quinidine, theophylline, and warfarin. Amiodarone inhibits the metabolism of calcium-channel blockers, phenytoin, quinidine, and warfarin. Of particular importance with amiodarone is its half-life of 1 to 2 months; it continues to inhibit drug metabolism for several months after it has been discontinued.

Other drugs are notable because their metabolism is inhibited by a variety of different drugs. The metabolism of the commonly used anticoagulant warfarin is inhibited not only by cimetidine and amiodarone but also by many other drugs, including alcohol, allopurinol, disulfiram, metronidazole, phenylbutazone, sulfinpyrazone, and trimethoprim-sulfamethoxazole. Similarly, the metabolism of phenytoin is inhibited by chloramphenicol, clofibrate, dicumarol, disulfiram, isoniazid (slow acetylators), phenylbutazone, and valproic acid.

Although most of these examples involve enzymes that metabolize the drug in the liver, drug-metabolizing enzymes outside the liver also may be affected by certain drugs. The best-known example is monoamine oxidase, which can be affected by nonspecific monoamine oxidase inhibitors, resulting in the accumulation of catecholamines at multiple sites after their release in response to the eating of tyramine-containing foods such as aged cheese, aged or cured meats, and any spoiled meat, poultry, or fish.

Decreased Excretion

Drugs can compete for the active transporters present in the kidney. Most of these interactions involve the acid transporters. The best-known interaction is probenecid's inhibition of penicillin transport, leading to decreased penicillin clearance and thus higher plasma levels, an interaction that was used in the past to maximize penicillin therapy. A similar inhibitory effect on the renal excretion of methotrexate can be produced by salicylates, phenylbutazone, and probenecid. The active transport of basic drugs (e.g., procainamide) can also be inhibited by other drugs (e.g., cimetidine, amiodarone).

Pharmacodynamic Drug Interactions

With pharmacodynamic interactions, drugs interact at the level of the receptor (target) or may produce additive effects by acting at separate sites on cells. An example of the first is the interaction of propranolol and epinephrine, which blocks β-adrenergic receptors; as a result, the α-adrenergic effects of epinephrine are unopposed. This undesirable interaction can result in severe hypertension.

Many examples exist of the additive effects of drugs. Aspirin, which can produce increased bleeding time by acting on platelets, can interact with warfarin, which affects clotting. The result is an increased risk for hemorrhage. Similarly, cardiac drugs, such as β-adrenergic blockers and calcium-channel blockers, have additive negative inotropic effects when they are coadministered, resulting in an increased risk for cardiac failure.

DIAGNOSIS AND PREVENTION OF DRUG INTERACTIONS

For a drug interaction to be recognized, the index of suspicion must be high whenever multiple drugs are used together. Because of the ever-increasing list of known and suspected drug interactions, it is impossible for a clinician to remember all or even many of the possible interactions.

Several clinical settings should raise concern about the possibility of drug interactions:

- The use of any drug with a low therapeutic index (Table 29-3) should be suspect.
- As the number of drugs being used concurrently increases, there is a disproportionately greater risk for drug interactions, particularly with more than 10 drugs.
- Critically ill patients who have multisystemic disease with compromised renal, hepatic, cardiac, or pulmonary function have an increased risk for drug interactions. This risk may be higher for patients with acquired immunodeficiency syndrome, who have an immunocompromised state and take a large number of drugs.
- Patients with various behavioral and psychiatric disorders (e.g., drug abusers taking a large number of prescription drugs as well as illicit drugs and alcohol) are at risk for drug interactions.

Another type of drug interaction that is becoming increasingly important is that between components of food (e.g., grapefruit juice) or natural products (e.g., herbs) and drugs. By inhibiting the intestinal cytochrome P-450 3A4 enzyme system, grapefruit juice can raise levels of drugs metabolized by this pathway (e.g., saquinavir, cyclosporine, verapamil) and result in toxicity or adverse drug effects.

Several steps can be taken to prevent drug interactions:

- When taking the medical history, it is important to document all drugs the patient is taking (and has recently taken), including prescription, over-the-counter, and other addictive drugs.
- It is desirable to minimize the number of drugs being taken by frequently reviewing the patient's drug list to ensure that each drug continues to be needed.
- There should be a high degree of suspicion when medications with a low therapeutic index known to have a high risk for drug interactions (see Table 29-3) are used.
- High-risk clinical settings, such as occur with critically ill patients, should raise the suspicion of adverse drug interactions.
- Adverse drug interactions should be considered in the differential diagnosis whenever any change occurs in a patient's course.

TABLE 29-3 DRUGS WITH LOW THERAPEUTIC INDICES AT HIGH RISK FOR ADVERSE DRUG RESPONSES AND DRUG INTERACTIONS

Anticoagulants
Antiarrhythmics
Anticonvulsants
Digoxin
Lithium carbonate
Oral hypoglycemics
Theophylline

ADVERSE REACTIONS TO DRUGS

An adverse drug response (ADR) is an undesired effect produced by a drug at standard doses, which typically necessitates reducing or stopping the suspected agent and may require treatment of the noxious effect produced. Further harm may occur with continued or future therapy with the drug.

EPIDEMIOLOGY

The financial impact of ADRs is estimated to be more than $100 billion per year. The actual incidence of ADRs is difficult to quantify because many cases are either not recognized or not reported. Several large studies have shown that the incidence may approach 20% for outpatients (even higher for patients taking more than 15 drugs) and 2 to 7% for inpatients. The incidence of ADRs increases exponentially with more than four drugs. Meta-analyses of several prospective studies suggest that ADRs are now the third leading cause of death in hospitalized patients. It is clear from more recent surveys that a relatively small group of drugs (see Table 29-3) continues to be implicated in most of the reported ADRs. Current trends suggest that the incidence of ADRs is likely to increase as a result of more prescribed and over-the-counter medications being used. Although still in an evolutionary phase, systems approaches have the potential to greatly advance the understanding of adverse drug events and the ability to predict them.[2]

PATHOBIOLOGY

Most ADRs are caused by an exaggerated (but predictable) pharmacologic effect of the drug or by a toxic or immunologic effect of the drug or a metabolite (not typically expected). Among an estimated 100,000 annual drug-related emergency hospitalizations in patients older than 65 years, the most commonly implicated drugs are warfarin (33%), insulin (14%), oral antiplatelet agents (13%), and oral hypoglycemic agents (11%).

Predictable Toxic Responses to Drugs

Exaggerated drug responses that cause adverse drug effects may be due to any condition that causes altered pharmacokinetics or pharmacodynamics (discussed earlier). There has been increasing interest in the discipline of pharmacogenomics, which explores the role of genetic factors in altered pharmacokinetics or pharmacodynamics and the resultant increased susceptibility to ADRs. Furthermore, a developing discipline of pharmacometabolomics should complement pharmacogenomics in personalized drug therapy by capturing environmental and microbiome-level influences on responses to drugs.[3] There is now ample evidence that molecular changes in the genes coding for drug-metabolizing enzymes can account for the variability in pharmacokinetics and drug effects observed in population studies. There are now many examples of the role of pharmacogenomics in altered drug response and effect. Three of the best-studied examples are genetic polymorphisms associated with debrisoquine-sparteine, *N*-acetylation, and mephenytoin. Each is associated with autosomal recessive inheritance, and together they are responsible for the metabolism of approximately 40 drugs (Table 29-4). Individuals with autosomal recessive genes are typically "poor metabolizers," with potentially altered pharmacokinetics that result in elevated plasma drug concentrations and can lead to toxicity. Recent studies have focused on genomic alterations associated with the variability in response to some commonly used drugs. Thus, the variability of response to warfarin (Chapter 38) is now understood to be due to single-nucleotide polymorphisms in the cytochrome P-450 2C9 (*CYP2C9*) and vitamin K epoxide reductase (*VKOR*) genes. These single-nucleotide polymorphisms have a significant effect on warfarin dose requirements. Similarly, polymorphisms in transporter genes can have profound effects on the pharmacokinetics of statins (Chapter 206). A common genetic variant of the organic anion-transporting polypeptide 1B1 can reduce the hepatic uptake of many statins, increasing the risk for statin-induced myopathy. Also, it is now appreciated that genetically impaired adenosine triphosphate (ATP)-binding cassette G2 transporter efflux activity can result in an increase in systemic exposure to various statins. Of particular importance to therapeutics is that the effects of these genetic polymorphisms differ, depending on the specific statin used.

TABLE 29-4 GENETIC POLYMORPHISMS OF DRUG-METABOLIZING ENZYMES

TYPE	PRIMARY DRUG EXAMPLES	OTHER DRUGS THAT ARE SUBSTRATES	INCIDENCE OF "POOR METABOLIZERS" IN WHITES (%)	ENZYME INVOLVED
Debrisoquine-sparteine polymorphism	Amitriptyline, codeine, tamoxifen	Antidepressants, antiarrhythmics, β-adrenergic receptor–blocking drugs, codeine, dextromethorphan, neuroleptics	5-10	Cytochrome P-450 IID6 (CYP2D6)
Mephenytoin polymorphism	Mephenytoin	Mephobarbital, hexobarbital, diazepam, omeprazole	4 (Japanese, Chinese, 15-20)	Cytochrome P-450 IIC (CYP2C)
N-acetylation polymorphism	Isoniazid, sulfadiazine	Hydralazine, phenelzine, procainamide, dapsone, sulfamethazine, sulfapyridine, aminoglutethimide, aminosalicylic acid, sulfasalazine	40-70 (Japanese, 10-20)	*N*-acetyltransferase (NAT2)
Methyl conjugation polymorphism	Catecholamines	L-Dopa, methyldopa	25-30	Catechol-*O* methyltransferase (COMT)

This provides a rational basis for an individualized approach to the use of lipid-lowering therapeutic agents.

A particularly impressive example occurs with certain cancer chemotherapy agents that have a relatively narrow therapeutic window and the potential to produce severe cytotoxicity (e.g., deficiency in dihydropyrimidine dehydrogenase activity can result in life-threatening toxicity after the administration of 5-fluorouracil). These defects typically are not recognized until the patient is given the drug. They are often described as "pharmacogenetic" syndromes.

Other genetic alterations do not affect metabolism specifically and do not produce a range of quantitative changes. These defects can produce "qualitative" defects and are often associated with structural defects. The classic example is glucose-6-phosphate dehydrogenase. Individuals who are deficient in this enzyme cannot tolerate the oxidative stress produced by some drugs, leading to hemolysis (Chapter 161). Drugs that can produce this clinical picture include aspirin, nitrofurantoin, primaquine, probenecid, quinidine, quinine, sulfonamides, sulfones, and vitamin K. Another similar defect is deficiency of methemoglobin reductase, which results in an inability to maintain iron in hemoglobin in the ferrous state, causing methemoglobinemia (Chapter 158) after exposure to oxidizing drugs such as nitrites, sulfonamides, and sulfones.

Unpredictable Toxic Responses to Drugs

Other toxic or immunologic ADRs are not predictable and are not obviously due to an increase in drug concentration (pharmacokinetic) or drug effect (pharmacodynamic). Unpredictable toxic responses include direct reactions between a drug and a specific organ (e.g., platinum-containing drugs, such as cisplatin, can produce direct toxicity in the kidney and the eighth cranial nerve). With other drugs, metabolism to an active intermediate must occur first. With a standard dose of acetaminophen, no untoward effects occur because the relatively small amount of reactive metabolite formed by oxidative metabolism is detoxified rapidly by reduced glutathione. In the presence of an overdose, the glutathione is depleted, and the remaining reactive metabolite can damage the liver. Understanding the mechanism of this toxicity has provided a rationale for treating acetaminophen overdose. Sulfhydryl-containing compounds (e.g., *N*-acetylcysteine), which can complex with the reactive metabolite, can be administered to reduce the amount of free toxic metabolite present, protecting the liver.

Immunologic reactions to drugs are generally not produced by the drug alone. Similar to other low-molecular-weight compounds (<1000 D), they are typically not antigenic themselves. When a drug or reactive metabolite combines with a protein to form a drug-protein complex, it can become antigenic, capable of eliciting an immune response.

Perhaps the most impressive form of drug allergy is anaphylaxis, which is due to an immunoglobulin E–mediated hypersensitivity. Many drugs from different classes have been shown to produce this type of drug allergy. The best-known example is the anaphylactic response produced by penicillin, which can occur after its administration by any route. Skin testing with penicillin G, penicilloic acid, or penicilloyl polylysine can identify patients at risk and should be performed in those with a suspected penicillin allergy who need treatment with penicillin. If the skin test result is positive, the patient must undergo desensitization before receiving penicillin. If the skin test result is negative, penicillin can be administered with caution.

DIAGNOSIS OF ADVERSE DRUG RESPONSES

Although many of the well-known adverse drug effects are due to a relatively small group of drugs, every drug has the potential to cause an ADR. A physician should always consider the possibility of an ADR in the differential diagnosis even if none has been reported previously for the particular drug. In earlier editions of this book, we provided a table listing many diverse clinical presentations associated with ADRs. The reader is now referred to the numerous websites providing more complete and up-to-date information on ADRs than can be detailed here. For example, *www.fdable.com* allows one to monitor drug safety with unlimited access to up-to-date information from the U.S. Food and Drug Administration (FDA) Adverse Event Reporting System (AERS).

In many instances, it is readily apparent that a specific drug has produced an ADR, such as the appearance of a rash in an otherwise healthy patient who was recently prescribed a single drug (e.g., penicillin). In other cases, the effect produced by the drug may be difficult to discern from other disease states. In still other cases, the adverse effect may mimic the illness being treated (e.g., development of an arrhythmia in a patient being treated with an antiarrhythmic drug).

From a public health perspective, it is highly desirable to have a mechanism available to detect, catalog, and track the incidence and severity of ADRs not only for drugs at various stages of development but also for drugs that were approved earlier. The FDA tracks adverse drug events through a voluntary reporting program, MedWatch. Health care professionals are encouraged to report any adverse events or product problems on a one-page form that can be sent by mail, fax, or electronically to the FDA. Nontraditional resources that are generated by patients via the Internet could supplement existing pharmacovigilance approaches.[4] Although various methods for surveying ADRs have been proposed, ultimately, the cooperation of alert clinicians, health care professionals, and patients must be encouraged.[4]

GENOMIC DATA PROVIDING GUIDANCE FOR CANCER THERAPEUTIC DECISION

In addition to genetic data being useful in understanding and increasingly predicting adverse drug effects (see earlier), it is becoming increasingly clear that genomic data (e.g., the presence of a specific genetic variant) can also help inform the clinician of the appropriate drug or dose of drug that should be used for the specific patient.[5,6] There is no therapeutic area in which this is more apparent than with oncologic drugs and particularly many of the new targeted therapy agents, for which the genomic profile of the tumor (vs. the host tissue) is critical.[7] A representative example is vemurafenib, a targeted agent that has recently been demonstrated to have therapeutic value in melanoma and potentially other malignancies as well. Vemurafenib is effective in tumors that have a specific mutation in their *BRAF* gene, a valine-to-glutamic acid mutation at residue 600 (V600E), that results in the oncogene protein product, BRAF(V600E) kinase, exhibiting a markedly elevated activity that overactivates the MAPK signaling pathway. Vemurafenib is an orally bioavailable, ATP-competitive, small-molecule inhibitor of BRAF(V600E) kinase with antineoplastic activity. It selectively binds to the ATP-binding site of BRAF(V600E) kinase and inhibits its activity, resulting in inhibition of an overactivated MAPK signaling pathway downstream in BRAF(V600E) kinase–expressing tumor cells, thereby reducing tumor cell proliferation. There are multiple other examples in oncology demonstrating that genomic

data from the tumor of an individual patient can be useful in making a therapeutic decision.

REVIEW QUESTIONS

1. A drug is considered to be effectively cleared from the circulation after how many half-lives?

A. 1.5
B. 2
C. 5
D. 7
E. 10

Answer: C A drug is considered to be effectively cleared when less than 10% of drug remains in the circulation. This is typically 3 to 5 half-lives.

2. Which one of the following drugs may be difficult to remove in an overdose setting because of a large volume of distribution (VD)?

A. Procainamide
B. Aspirin
C. Digoxin
D. Phenobarbital
E. Phenytoin

Answer: C A large VD indicates that a large fraction of the specific drug is present outside the circulation. Examination of drugs in Table 29-1 demonstrates that digoxin's V_D is much higher than the other four drugs such that, in an overdose situation, easy removal of digoxin from the affected individual would be difficult because a large fraction of the drug is outside the circulation and therefore relatively inaccessible.

3. The antihistamine terfenadine (Seldane) should not be administered with which one of the following fruit juices?

A. Lemon juice
B. Orange juice
C. Prune juice
D. Grapefruit juice
E. Apple juice

Answer: D Many drugs are metabolized by CYP3A4 in the small intestine. Certain chemicals in grapefruit juice, but not in the other juices listed, block the action of CYP3A4, so instead of being metabolized, more of the drug enters the blood stream and stays in the body longer. The result is that potentially dangerous levels of the drug accumulate. This finding has led to more attention to foods, herbs, and other natural substances that are coadministered with drugs.

4. Which one of the following drugs has pharmacokinetics characterized as dose-dependent, nonlinear saturation kinetics?

A. Digoxin
B. Tobramycin
C. Lidocaine
D. Glimepiride
E. Phenytoin

Answer: E Not all drugs behave the same when drug dose is increased. The elimination of most drugs follows first-order or linear kinetics, such that the amount of drug eliminated is directly proportional to the plasma concentration of the drug. A few drugs (e.g., phenytoin) have a different pattern of elimination—that is, dose-dependent, nonlinear kinetics—such that as the drug dose increases and the plasma concentration of the drug rises, the relative amount of the drug being eliminated falls (i.e., clearance decreases) until the rate of drug metabolism is at a maximum. At this point, drug elimination is said to be zero order, and the drug concentration in plasma starts to increase much more (no longer linear). This is shown in Figure 29-5B.

5. Before administration of vemurafenib, which one of the following genes should be monitored for the presence of a V600E single-nucleotide polymorphism?

A. EGFR
B. BRAF
C. NMYC
D. VEGF
E. CMYC

Answer: B The effectiveness of vemurafenib in tumors has been demonstrated to be dependent on the presence of a specific mutation in the *BRAF* gene of the tumor, a valine-to–glutamic acid mutation at residue 600 (V600E). This mutation results in the oncogene protein product, BRAF(V600E) kinase, exhibiting a markedly elevated activity that overactivates the MAPK signaling pathway. Vemurafenib selectively binds to the adenosine triphosphate–binding site of BRAF(V600E) kinase and inhibits its activity, resulting in inhibition of an overactivated MAPK signaling pathway downstream in BRAF(V600E) kinase–expressing tumor cells, thereby reducing tumor cell proliferation. Before considering this drug, specific testing for the presence of this mutation is recommended.

30 PAIN

STEVEN P. COHEN AND SRINIVASA N. RAJA

Pain is ubiquitous in life, usually serving as a warning sign of impending or actual injury to the organism. As such, pain is older than humans, dating back to our most primitive ancestors. Pain is also a vital diagnostic clue for physicians. Physicians should be intimately familiar with pain, for it is the most common symptom for which patients seek medical attention.

It is difficult to overestimate the impact that pain has on society. According to an Institute of Medicine report released in 2011, one in three Americans suffer from chronic pain, which is more than the total affected by heart disease, cancer, and diabetes combined. Among the various types of pain, back pain is the most common, followed by severe headaches, arthralgias, and neck pain. The estimated economic cost of chronic pain, to include medical costs and lost productivity, ranges between $560 and $635 billion (in 2010 dollars).[1] Spinal pain is the leading cause of disability in individuals younger than 45 years in industrialized nations, with the economic costs exceeding $100 billion annually in the United States by some estimates. Special populations at risk for chronic pain include the elderly, and individuals with physical and psychological morbidities. Several conditions characterized by chronic pain, such as headaches, irritable bowel syndrome, fibromyalgia, and complex regional pain syndrome, are more prevalent in women than in men.

DEFINITION

The International Association for the Study of Pain defines pain as "an unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage." This definition recognizes that pain may be experienced in some circumstances in the absence of ongoing tissue damage (e.g., phantom pain after a healed amputation). One implication of this construct is the assumption that pain is always subjective; hence, a patient's report of pain should always be accepted at face value in the absence of evidence to the contrary.

PATHOBIOLOGY

Classification of Pain States

Multiple classifications have been used to describe pain states on the basis of duration, anatomic source, and etiology. *Acute pain* usually results from injury or inflammation, has survival value, and may play a role in healing by promoting behaviors that minimize reinjury. In contrast, *chronic pain* is perhaps best construed as a "disease" that serves no useful purpose. Although there is no clear threshold at which acute pain transitions to a chronic state, it is generally accepted that pain persisting beyond the expected healing period is pathologic. In most cases, this period is between 3 and 6 months. The intensity of pain can be classified as mild (1 to 3), moderate (4 or 5), or severe (≥6 on a 0 to10 numerical rating scale).

Somatic and Visceral Pains

Pain can originate from somatic or visceral structures. *Somatic pain* is typically well localized and generally results from injury or disease of the skin, musculoskeletal structures, and joints. Different types of stimulation can evoke pain by binding to distinct receptors (also known as nociceptors), which can be broadly categorized as chemosensitive, thermosensitive, mechanosensitive, or polymodal. *Visceral pain* arises from internal organ dysfunction and can result from inflammation, ischemia, occlusion of flow resulting in capsular or organ distention (e.g., renal stones, bowel obstruction, cholecystitis), or functional disease (e.g., irritable bowel syndrome). In contrast to somatic pain, visceral pain is usually diffuse and poorly localized, is often referred to somatic regions (e.g., myocardial ischemia radiating into the arm), and tends to be associated with exaggerated autonomic reflexes and greater emotional features. Some of the reasons for these differences between somatic and visceral pain include a lower density and different types (e.g., distention sensitive) of nociceptors in visceral structures and convergence with afferent pathways predominantly populated by somatic pain in the spinal cord.

Neuropathic, Nociceptive, and Mixed Pain

Pain can be etiologically classified as neuropathic, nociceptive, or mixed (Table 30-1). *Neuropathic pain* has been defined as pain arising as a direct consequence of a lesion or disease affecting the somatosensory system. Common peripheral neuropathic pain states include post-herpetic neuralgia, diabetic neuropathy, and radicular pain. One subtype of neuropathic pain is central pain, which is manifested as a constellation of symptoms requiring a primary lesion to the central nervous system as a necessary (but not sufficient) inciting event. Owing to its high prevalence, the most common overall cause of central pain is central post-stroke pain (occurring after approximately 8% of cerebrovascular accidents), although spinal cord lesions (e.g., syringomyelia or spinal cord injury) are associated with a higher incidence of central pain (>50%). Epidemiologic studies indicate that neuropathic pain is prevalent in 7% to 8% of the population, and that 20% to 25% of all chronic pain is neuropathic in nature. *Nociceptive pain* usually results from an injury or disease affecting somatic structures such as skin, muscle, tendons and ligaments, bone, and joints. Pain associated with cancer can result either from the tumor itself or as a consequence of therapy (e.g., surgery, chemotherapy, and radiation therapy). In light of the often multiple different causes, advanced cancer pain is a typical example of a mixed pain state.

Dysfunctional Pain

There is a group of pain syndromes that have been characterized by amplification of pain signaling in the absence of either inflammation or injury (as in nociceptive pain) or damage to the nervous system (as in neuropathic pain). These conditions include pain states such as fibromyalgia, irritable bowel syndrome and interstitial cystitis. The precise pathophysiologic mechanisms of pain in these disorders are still being elucidated, although they share some features of neuropathic pain such as augmented sensory perception and altered central neurotransmission.

Pain Mechanisms

Pain results from activation of specialized peripheral receptors (*nociceptors*) by a noxious event (stimulus). These receptors respond to various external stimuli: *mechanical* (e.g., pressure, tumor growth, incision), *thermal* (e.g., hot or cold), or *chemical* (e.g., ischemia or infection). In addition to distinct nociceptors that respond to each type of stimulus, there are also *polymodal* nociceptors that respond to multiple stimulus modalities. Once a stimulus is detected, it is converted into an electrical nerve signal (*transduction*), which is conveyed along the axons of thinly myelinated (A delta) or unmyelinated (C) nerve fibers through specific pathways (*transmission*). *Modulation* generally refers to the attenuation of pain signals through intrinsic inhibitory activity within the peripheral and the central nervous systems before being perceived as an unpleasant sensation (*perception*), though in some cases pain signals may be amplified during this process. *Pathologic pain* is the result of injury- or disease-induced changes in the peripheral or central nervous systems leading to alterations in pain signaling. One important example of pathologic pain from injury to the nervous system is *peripheral sensitization*. This form of pain is characterized by the development of spontaneous ectopic activity in injured nerves and dorsal root ganglion cells as well as enhanced sensitivity to mechanical, thermal, or chemical stimuli.

Prolonged and repeated activation of nociceptive afferent fibers produces *central sensitization*, a state of increased sensitivity of central pain signaling neurons. Activation of *N*-methyl-D-aspartate (NMDA) receptors by glutamate is thought to be an important mechanism for central sensitization. Studies indicate that in addition to functional changes in neurons, microglia and astrocytes may also play an important role in the central sensitization process. Other central neuroplastic changes that may contribute to neuropathic pain states include deafferentation hyperactivity that may occur after spinal cord or avulsion injuries, loss of large-fiber inhibition, reorganization of central connections of primary afferent fibers, and excitatory descending modulatory mechanisms. Central and peripheral sensitization are considered to be the prime culprits responsible for pain induced by innocuous stimuli (*allodynia*) and increased pain to normally noxious stimuli (*hyperalgesia*)

TABLE 30-1 CLASSIFICATION AND PREVALENCE OF COMMON PAIN CONDITIONS

NEUROPATHIC		*NOCICEPTIVE*		*MIXED*
Peripheral*	***Central***	***Somatic***	***Visceral***	
Peripheral neuropathy (1-3%)	Central post-stroke pain (8%)	Arthritis (25-40% in people > 40 years)	Endometriosis (10% in women of reproductive age)	Headache (15% for migraine, 20-30% for tension type)
Post-herpetic neuralgia (annual incidence 0.1-0.2%)	Spinal cord injury (30-50%)	Myofascial pain (5-10%)	Irritable bowel syndrome (5-15%)	Cancer[§] (lifetime prevalence 30-40%)
Chronic postsurgical pain (5-20% after surgery)	Multiple sclerosis (25%)	Fibromyalgia[†] (2-4%)	Interstitial cystitis (0.2-1% of women)	Low back pain[‖] (point prevalence 10-30%)
Phantom limb pain (30-60%)	Parkinson disease (10%)	Connective tissue disorders (0.2-0.5%)	Ulcers, gastritis, esophagitis (3-9%)	Neck pain[‖] (annual incidence 20-30%)
Trigeminal neuralgia (0.01%)	Seizure disorder (1-3%)	Burn pain[‡] (annual incidence of burns requiring hospitalization 0.01%)	Cholecystitis, appendicitis	Ischemic pain[¶]
Radiculopathy, spinal stenosis (3%-10%)				
Complex regional pain syndrome (0.03%, 3-20% after orthopedic surgery)				
Nerve entrapment syndromes (e.g., carpal tunnel, thoracic outlet, meralgia paresthetica; 2-4%)				

*Prevalence rates represent proportion of patients with condition who develop pain.
†Some cases may represent a variant of central pain.
‡Third-degree burns are often associated with neuropathic pain.
§Neuropathic pain occurs in 20 to 50% of cases and may be secondary to tumor invasion, surgery, chemotherapy, and radiation treatment.
‖Neuropathic pain may accompany nociceptive pain in 10 to 35% of cases.
¶Typically nociceptive, but long-standing pain may result in ischemic neuropathy.

that are commonly observed in neuropathic pain states. Studies have shown an important role for neurotrophins, prostaglandins, cytokines such as tumor necrosis factor-α and interleukins, and glial cells in the sensitization processes.[2]

Genetics

Chronic pain is a prototypical example of the interplay between genes and environment. Although tissue or nerve injury is necessary for the development of most pain syndromes, by itself it is not sufficient, as only a small percentage of injuries result in chronic pain. There are many ways in which one's genetic makeup can influence pain to include differences in pain sensitivity, susceptibility to disease, immunomodulatory response to injury, psychological predisposition to pain persistence, interactions between genotype differences and environment, and response to analgesic therapy. Not only genetics but also epigenetics can affect how painful stimuli are perceived.

Heritability is estimated to account for between 30% and 60% of the variance in pain response and has been demonstrated to play a role in acute pain perception and the transition from acute injury to chronic pain.[3] Even when the variability associated with gender and racial differences is taken into consideration (i.e., women and African Americans are more likely to report pain than are men and whites, respectively), genetics continues to play a major role in explaining pain differences. Heritable pain conditions may occur through either dominant or recessive gene transmission, and involve an assortment of different phenotypes.

Although rare, examples of monogenic (single-gene mutation) pain conditions include hereditary sensory and autonomic neuropathies, familial hemiplegic migraine, and neurologic channelopathies such as primary erythromelalgia, which involves a mutation at the gene encoding the voltage-gated sodium channel Nav 1.7. This latter mutation causes increased excitability and ongoing activity in afferent sensory neurons.

More common are those conditions associated with multiple gene abnormalities and incomplete penetrance, with about a dozen genes accounting for more than half of the identified gene candidates. In most cases, genes may promote a predisposition to pain, which requires a subsequent environmental inciting event (e.g., an injury in the context of depression) for manifestation.

Compared with other specialties, the study of the genetic basis for pain variability is still in its infancy, with most research revolving around conditions containing pain as a major symptom (e.g., endometriosis, osteoarthritis) rather than pain itself as an independent measure. In the future, the translational application of genetic studies may involve the suppression of pain-facilitating alleles, increasing the expression of pain-protective alleles, and targeted analgesic therapies.

DIAGNOSIS

History

Similar to the work-up of any symptom, the evaluation of pain begins with a thorough history. One of the primary tenets of pain assessment is that subjective complaints should always be taken seriously. There is no diagnostic test that can measure pain or even ascertain its existence. The most promising techniques involve functional brain imaging that reflects cerebral metabolism. These research tools have helped us understand that the brains of chronic pain patients are different from those of normal individuals and undergo morphologic alterations such as a diminution in gray matter in the areas involved in pain perception. Studies have confirmed that these deleterious changes are a consequence, not a cause, of chronic pain and may be reversed by effective treatment.[4]

A comprehensive history should include the location of pain and its quality, exacerbating and relieving factors, temporal aspects, associated symptoms and signs (e.g., numbness or weakness), interference with activities of daily living, and response to prior treatments. The temporal aspects of pain can provide valuable clues to etiology. Most cases of acute pain develop subsequent to a specific inciting event (e.g., surgery, trauma), whereas chronic pain conditions are usually more insidious in onset. Because acute pain tends to be self-limited and the relationship to a precipitant event is more tangible, it is generally better tolerated and associated with fewer psychological sequelae.

The severity of pain can be measured by a variety of different rating scales. Some of the more common instruments include categorical scales, verbal and numerical rating scales (0 to 10), and the visual analog scale, in which a 10-cm line is anchored on each side by two points designated "no pain" and "worst possible pain." Because there are subtle differences between different scales, repeated assessments of response to therapy are ideally gauged by the same instrument. For young children and mentally incapacitated patients, the use of age-appropriate substitute scales or facial expressions has been validated.

Recent guidelines from experts across multiple specialties have concluded that pain scores represent only one component of pain management. Other important aspects of treatment include assessments of functional capacity (e.g., Oswestry disability index for back pain), psychological and emotional functioning, satisfaction ratings, adverse treatment effects and disposition (i.e., work status). It is therefore imperative that realistic goals be established and individually tailored treatment regimens be developed to achieve these ends.

Distinguishing between neuropathic and nociceptive pain can have important treatment implications (Table 30-2). Neuropathic pain is characterized by positive and negative symptoms. Negative symptoms, such as a loss of sensation, are usually the result of axon or neuron loss, whereas positive

TABLE 30-2 CATEGORIZATION OF NEUROPATHIC AND NOCICEPTIVE PAIN

CLINICAL CHARACTERISTIC	NEUROPATHIC PAIN	NOCICEPTIVE PAIN
Etiology	Nerve injury or peripheral or central sensitization	Tissue or potential tissue damage
Descriptors	Lancinating, shooting, electrical-like, stabbing	Throbbing, aching, pressure-like
Sensory deficits	Frequent (e.g., numbness, tingling, pricking)	Infrequent and, if present, in nondermatomal or non-nerve distribution
Motor deficits	Neurologic weakness may be present if motor nerve affected	May have pain-induced weakness
Hypersensitivity	Pain frequently evoked with nonpainful (allodynia) or painful (exaggerated response) stimuli	Uncommon except for hypersensitivity in the immediate area of an acute injury
Character	Distal radiation common	Distal radiation less common; proximal radiation frequent
Paroxysms	Exacerbations common and unpredictable	Exacerbations less common and associated with activity
Autonomic signs	Color changes, temperature changes, swelling, or sudomotor (sweating) activity occurs in one third to one half of patients	Autonomic signs uncommon in chronic nociceptive pain

symptoms reflect abnormal excitability of the nervous system. Numbness, tingling, and other symptoms suggestive of sensory dysfunction are strongly indicative of neuropathic pain, especially when they occur in a dermatomal or nerve distribution. Descriptors such as "burning," "shooting" and "electrical" are more likely to be associated with neuropathic pain, whereas adjectives such as "throbbing" and "aching" tend to be identified with nociceptive pain states such as arthralgias. Other positive symptoms observed in neuropathic pain states include pain evoked by normally innocuous stimuli (allodynia), and an exaggerated or prolonged pain response to noxious stimuli (hyperalgesia, hyperpathia). Although neuropathic pain tends to be more intermittent than nociceptive pain, mechanical spinal pain is classically exacerbated by movement. As alluded to earlier, some conditions, such as cancer, may be characterized by aspects of both nociceptive and neuropathic pain. There are several patient-report instruments available that may help distinguish neuropathic from nociceptive pain (e.g., painDETECT, s-LANSS, and DN4),[5] although determination by the physician through history, examination, and diagnostic testing remains the reference standard.[6]

A thorough history should evaluate sleep patterns. In epidemiologic studies, more than 50% of chronic pain patients exhibit some form of sleep disturbance, and sleep abnormalities are nearly ubiquitous in some conditions such as fibromyalgia. It is well known that pain can interfere with sleep, but what is not as commonly appreciated is that sleep deprivation may enhance pain sensitivity by lowering nociceptive thresholds and reduce response to analgesic therapy. Evidence also exists for a relationship between poor sleep and the development of chronic pain after an acute event. Although there is some evidence that improved sleep may lessen chronic pain, these studies are mostly correlational.

The proper evaluation of the patient in pain must include a psychosocial history. Between one half and two thirds of chronic pain patients exhibit varying degrees of psychopathology, with depression being the most common comorbidity, followed by anxiety disorders, somatoform disorders, and substance abuse. Many of these coexisting psychological conditions have been associated with poor treatment prognosis. People seeking chronic pain care may also be more likely to carry a concomitant axis II diagnosis (i.e., personality disorder), which can act as an additional barrier to effective treatment. Potential social factors that can have a negative impact on treatment should be identified, including low job satisfaction and secondary gain. A focused psychosocial history that includes prior psychiatric diagnoses, suicidal ideation, work history, legal history, and substance abuse is therefore essential in the formulation of a treatment plan.

Physical Examination

Examination of the patient in pain should encompass all body systems because pain is a frequent manifestation of systemic disease. A physical examination finding by itself is almost never pathognomonic but usually functions to confirm suspicions garnered from the history and to select patients for imaging studies or invasive diagnostic testing. Unlike acute pain, chronic pain is usually not associated with autonomic activation resulting in altered vital signs or facial grimacing.[7] Sensory symptoms can precede other neurologic findings by months or weeks. The most common forms of neuropathy are associated with sensory deficits in a glove-stocking distribution, but other patterns occur as well (Chapter 420). Numbness in the distribution of a nerve root or single nerve strongly suggests neuropathic pain, but nondermatomal sensory changes can accompany nociceptive pain (e.g., fibromyalgia) as well. Allodynia and hyperalgesia are hallmarks of neuropathic pain. Postural and gait abnormalities may be either causative factors for rheumatologic conditions (e.g., bursitis) or consequences of the underlying condition.

A careful evaluation of passive and active range of motion is useful because generalized and regional pain complaints are often accompanied by deconditioning. Distinctions should be drawn between pain-induced and neurologic weakness, with the latter often occurring in conjunction with muscle atrophy or asymmetry in reflexes. Sometimes reflex assessment is the only way to distinguish between a true neurologic condition and nonorganic causes.

Diagnostic Tests

Imaging has largely supplanted history and physical examination as the "gold standard" for diagnosis of disease but is not without drawbacks. There is a poor correlation between findings on magnetic resonance imaging (MRI) and the intensity of spinal pain, with more than 50% of asymptomatic individuals having abnormalities on lumbar, thoracic, and cervical films. Systematic reviews have found that early imaging for back pain does not improve outcomes or affect decision making and should be reserved for those patients with indications of a serious underlying condition.■ Absolute indications for MRI in patients with back pain are serious or progressive neurologic deficits, new-onset bowel and bladder dysfunction, suspected metastatic disease or infection, and referral of patients for procedural interventions. Yet, some have even questioned the utility of imaging as a prognostic tool before procedures. In a randomized trial evaluating whether MRI improved treatment outcomes in patients with sciatica who were referred for epidural steroid injections, preprocedure MRI was not shown to improve outcomes and only infrequently altered decision making.■ For back pain, the presence of "red flags" suggestive of more serious disease (e.g., trauma history, infection, history of intravenous drug abuse) should also alert the practitioner to seek further evaluation. For nonspinal pain conditions, MRI is ideal for discerning inflammation and soft tissue disease, whereas computed tomography scanning may be better for detecting bleeding and bone disease. The main advantage of ultrasound is that it is inexpensive and not associated with radiation. For chronic pain disorders, such as primary headaches and chronic abdominal or pelvic pain, imaging should be reserved for the evaluation of acute processes or a significant change in symptoms.

Electromyography and nerve conduction studies (Chapter 420) can be used to diagnose injury to large nerve fibers. However, because these studies are associated with significant false-negative and false-positive rates and are not sensitive in detecting impairment of small-fiber function, normal findings on a neurophysiologic study do not rule out neuropathic pain. For small-fiber neuropathies, a skin biopsy demonstrating decreased density of epidermal nerve fibers is a sensitive test.

TREATMENT

Rx

The goals of treatment should include elucidating the cause of pain and alleviating suffering. The biopsychosocial model posits that biologic, psychological, and social factors all play a role in chronic pain and should be addressed. Consequently, the goal of pain treatment should not be limited to pain reduction but also encompass improving function, psychological comorbidities, sleep, and social interaction. It has been argued that treatment should be mechanism based rather than etiology based, but at present, simple clinical tools to correlate symptoms and signs with mechanisms are lacking. The future development of diagnostic methods to identify mechanisms (e.g., intravenous

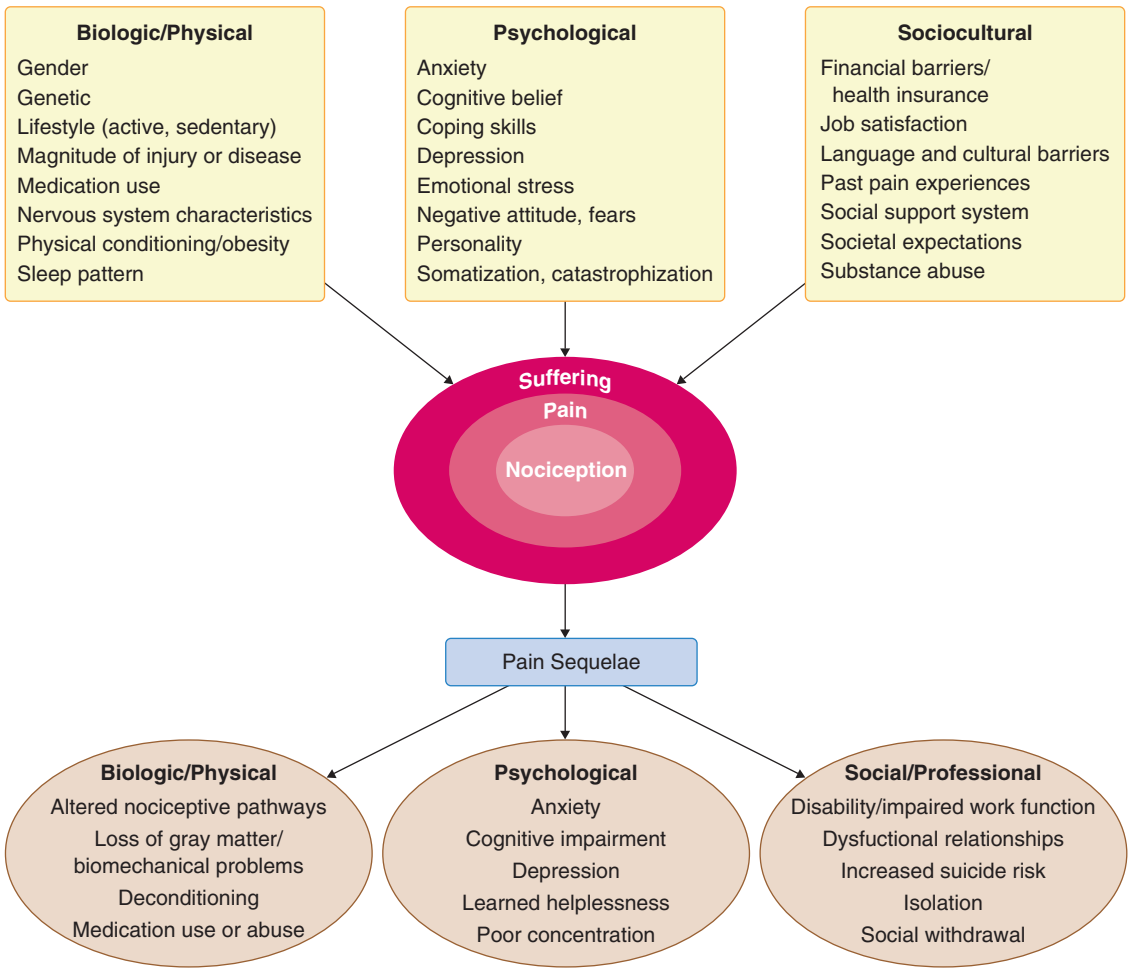

FIGURE 30-1. Schematic drawing of the biopsychosocial model of pain.

infusion tests) may help develop novel target-specific pharmacologic agents (Fig. 30-1).

Pain is a complex perceptual experience affected by a multitude of factors that include not only activation of nociceptors but also emotions, memory and cognition, social and cultural context, and expectations. Therefore, despite a paucity of studies evaluating a multidisciplinary approach to pain management, a strong consensus exists that this approach is beneficial.

Pharmacologic Therapies

Antipyretic Analgesics

Aspirin (Chapter 37) is the most widely used analgesic in the world. Along with its pharmacologic cousins nonsteroidal anti-inflammatory drugs (NSAIDs) and the antipyretic drugs acetaminophen and phenacetin, this group forms the backbone of pharmacologic pain treatment. Antipyretic analgesics exert their antinociceptive effects by the inhibition of cyclooxygenase, the rate-limiting enzyme in the production of prostaglandins, which sensitize nociceptors and regulate inflammation. There are several pharmacologic distinctions between NSAIDs and their counterparts, phenazone and acetaminophen. Whereas NSAIDs act both centrally and peripherally, making them effective topical agents for nociceptive inflammatory conditions, the primary site of enzyme inhibition for acetaminophen is in the central nervous system. Acetaminophen is also a weaker analgesic than NSAIDs and is largely devoid of anti-inflammatory effects.

The main drawback of nonopioid antipyretic analgesics is their ceiling effect, which can render them ineffective as stand-alone agents for severe pain. For cancer pain, the World Health Organization treatment paradigm advocates adding opioids to an analgesic regimen uncontrolled by NSAIDs, not replacing them. NSAIDs may act synergistically with opioids and have proven opioid-sparing effects. It is well acknowledged that aspirin, NSAIDs, and acetaminophen are more effective in treating nociceptive than neuropathic pain, although many neuropathic pain sufferers regularly take NSAIDs.

A major concern about nonopioid antipyretic agents is side effects. For NSAIDs, these include bleeding, gastrointestinal ulceration, renal toxicity, and increased risk of cardiovascular events (Chapter 37). Although the use of cyclooxygenase 2–selective inhibitors, such as celecoxib, or the addition of protein pump inhibitors to conventional NSAIDs may attenuate the risk of bleeding and ulcers, they do not affect the incidence of adverse renal or cardiovascular events. These risks are significantly increased in the elderly, in patients with multiple comorbidities, and with polypharmacy. In view of their considerable risks, NSAIDs should be prescribed in the lowest dose possible, for the shortest duration of time, and with periodic surveillance. Because it possesses a more favorable safety profile, acetaminophen is often considered a first-line therapy before NSAIDs, even for pain conditions associated with inflammation. Topical NSAIDs (e.g., diclofenac) have also been shown in randomized controlled studies to be beneficial for the treatment of rheumatologic disorders and have been touted as having comparable efficacy for regional pain conditions but with fewer adverse effects than systemic NSAIDs.

Adjuvant Analgesics

Multiple evidence-based guidelines for the treatment of chronic pain states, particularly neuropathic pain, have been published (Table 30-3). In general, these suggest that antidepressants and anticonvulsants should be the two first-line classes of medications for chronic neuropathic pain.[8,9] Depending on the particular drug and condition, these medications have been demonstrated to provide significant pain relief in carefully selected patients beyond that observed with placebo in 10 to 40% of ideal pharmacologic candidates. Whereas opioids have shown similar efficacy for neuropathic pain, anticonvulsants and antidepressants carry a lower risk of serious adverse events and long-term tolerance, rendering them preferable for long-standing noncancer pain (Table 30-4). In terms of efficacy, tricyclic antidepressants (TCAs) are superior to serotonin-norepinephrine reuptake inhibitors, which in turn are more efficacious than serotonin-specific reuptake inhibitors. However, because of their more favorable side effect profile, serotonin-norepinephrine reuptake inhibitors may be more effective than TCAs in some patients. Among the various TCAs, amitriptyline is the most studied but is probably comparable in efficacy to its metabolite nortriptyline and cousin imipramine. However, the last two drugs' more favorable side effect profiles (e.g., less sedation and anticholinergic activity) make them the preferred choices for neuropathic pain. In patients who cannot tolerate TCAs, serotonin-norepinephrine reuptake inhibitors such as duloxetine can be beneficial. In addition to neuropathic pain, antidepressants have also been shown to be effective in headache prophylaxis, abdominal and pelvic pain, fibromyalgia, and musculoskeletal pain.

Anticonvulsants are effective for neuropathic pain by virtue of their membrane-stabilizing properties. Although anticonvulsant drugs may be

Third Line	**Third Line**	**TRIGEMINAL NEURALGIA**
Antiepileptics	Tramadol	**First Line**
Mexiletine	Opioid analgesics	Carbamazepine
Memantine		Oxcarbazepine
Antidepressants		**Second or Third Line**
Dextromethorphan		Surgery
Topical capsaicin		
	Fourth Line	**CENTRAL PAIN**
	Cannabinoids	**First Line**
	Methadone	Gabapentin
	SSRI: citalopram, paroxetine	Pregabalin
	Other anticonvulsants: lamotrigine, topiramate, valproic acid	TCA
		Second or Third Line
	Miscellaneous agents: mexiletine, clonidine	Cannabinoids (multiple sclerosis)
		Lamotrigine
		Opioids
		Tramadol (spinal cord injury)

*Guidelines not disease specific, but for neuropathic pain in general.
†Consider lower starting dosages and slower titration in geriatric patients.
EFNS = European Federation of Neurological Societies; ER = extended release; NeuPSIG (IASP) = Neuropathic Pain Special Interest Group of the International Association for the Study of Pain; SNRI = serotonin norepinephrine reuptake inhibitors; SSRI = selective serotonin reuptake inhibitors; TCA = tricyclic antidepressant.

better than antidepressants for prototypical "lancinating-type" neuropathic pain, antidepressants are more versatile in that they have proven benefit in myriad other pain conditions. Owing to their high efficacy and favorable side effect profiles, gabapentin and pregabalin are first-line agents for most forms of neuropathic pain. In addition to independent pain-relieving properties, randomized controlled trials suggest that these drugs may act synergistically with opioids and antidepressants, provide anxiolysis, and exhibit preemptive analgesic effects when administered before surgery.

When gabapentinoid drugs are ineffective or intolerable, alternative anticonvulsants that act by different cellular mechanisms, such as lamotrigine and oxcarbazepine, may be employed. For trigeminal neuralgia, carbamazepine remains the treatment of choice, although adverse effects, such as the risk of agranulocytosis, limit its utility for other conditions. Other classes of adjuvants that may be effective in certain contexts include topical creams (e.g., capsaicin), *N*-methyl-D-aspartate antagonists (e.g., dextromethorphan), skeletal muscle relaxants (e.g., baclofen), cannabinoids, and antiarrhythmics (mexiletine). Topical lidocaine patches have been shown to reduce pain and allodynia in patients with post-herpetic neuralgia, and anecdotal evidence has suggested that they may be useful in the treatment of certain types of back pain. A high-concentration (8%) topical patch of capsaicin (the pungent chemical in chili pepper) has been demonstrated in clinical trials to provide significant pain relief compared with placebo for post-herpetic neuralgia and HIV neuropathy. A single 1-hour application can result in attenuation of pain for up to 12 weeks.

Opioid Analgesics

Opioid analgesics are the cornerstone of treatment for cancer pain (Table 30-5). Although randomized studies have found that opioids are effective in noncancer pain conditions, several reviews[12,13] and guidelines have concluded that they provide long-term improvement in only a minority of individuals, and that their superiority to other analgesics and ability to improve function are limited or inconclusive. Maximizing the therapeutic effects of opioid analgesics requires careful attention to balancing the beneficial effects with the undesirable adverse effects, including addiction. Understanding the clinical pharmacology of opioids, including their relative potency, duration of action, bioavailability, and pharmacokinetics, is essential for rational use. Their use for chronic pain management is limited primarily by myriad side effects that include nausea, constipation, sedation, itch, respiratory depression, and endocrine deficiency leading to sexual dysfunction and accelerated osteoporosis. Aggressive management with stool softeners and agents that enhance bowel motility, such as docusate and senna, can minimize constipation. Whereas most opioids are devoid of end-organ toxicity, an exception is meperidine. A metabolite, normeperidine, can accumulate after several days of treatment, causing myoclonus and anxiety; at higher concentrations, confusion, delirium, and seizures can ensue. Opioids that are predominantly renally eliminated, such as morphine, should be used with caution in patients with renal dysfunction. Two metabolites of morphine, morphine-6-glucuronide, which contains analgesic properties, and morphine-3-glucuronide, which may amplify pain in certain contexts, can accumulate in patients with renal dysfunction and contribute to the adverse effects of morphine. Alternative drugs include fentanyl and methadone.

For treatment of acute pain or an exacerbation of chronic pain in hospitalized patients (e.g., sickle cell crisis), patient-controlled analgesia (PCA) provides a convenient means of administering opioids. Intravenous morphine, fentanyl, or hydromorphone is commonly administered with an infusion device wherein a basal infusion, bolus dose, lockout interval, and maximum dose per hour can be programmed. PCA devices are safe and allow patients to control their pain management with less dependence on health care providers. Studies comparing PCA with conventional administration of opioids have generally found PCAs to be associated with better pain relief and higher satisfaction rates, albeit with larger amounts of medication consumed.

Critical steps in managing chronic pain patients with opioids include appropriate evaluation, clear and detailed documentation, a function-based treatment plan with well-defined patient goals that include an exit strategy, a written patient-physician agreement that includes informed consent and patient education, periodic review that focuses on progress toward functional goals, and specialist referrals in managing difficult patients. When considering a trial with opioids, health care providers need to consider the disease process, to assess traits such as compliance and responsibility, to perform risk stratification, and to monitor for predefined treatment goals and aberrant drug-related behaviors (Fig. 30-2).

The long-term use of opioids can be associated with tolerance and physical dependence. Cross-tolerance among opioids is not complete, and a strategy often used when tolerance is suspected is rotation to an alternative opioid, which may result in a 30 to 50% reduction in equianalgesic dose. Rates of addiction (Chapters 31 and 34) in reported studies vary widely, from less than 5% to 50%, which reflects differences in populations studied, definitions, and surveillance methods. A synthesis of evidence suggests that among chronic pain patients receiving opioid therapy, up to 40% will exhibit aberrant drug-related behaviors, 20% will abuse their drugs, and around 10% may become addicted.

Tramadol and tapentadol represent a newer class of analgesic drugs that have a dual mechanism of action. Tramadol is a weak agonist that inhibits the reuptake of norepinephrine and serotonin. Along with the usual side effects associated with opioids, seizures have been reported with tramadol, and adverse drug interactions can occur in patients taking coumadin and selective serotonin reuptake inhibitors. Tapentadol also has a dual mode of action as a μ-opioid agonist and a norepinephrine reuptake inhibitor and is slightly stronger than tramadol. Tramadol is presently approved for moderate to moderately severe severe pain. Tapentadol is approved for moderate to severe acute pain, while its extended-release formulation is approved for moderate to severe chronic pain and diabetic neuropathy.

Butorphanol, nalbuphine, and pentazocine are opioid agonist-antagonist drugs that can antagonize the actions of μ-opioid agonists and cause psychotomimetic effects due to their actions on the κ-opioid receptor. These drugs should be used with caution, particularly in patients receiving other μ-opioid agonists as they may precipitate withdrawal or reduce the effectiveness of pure opioid agonists. Buprenorphine, a partial agonist at the μ-opioid receptor and an antagonist at other opioid receptors, is available in various formulations, including a once per week transdermal patch for pain, and in combination with naloxone for the treatment of opioid addiction.

Combination Therapies

Most clinical trials have studied individual drugs in specific chronic pain states. Because no drug is universally effective and most provide only partial

TABLE 30-4 ADJUVANT ANALGESIC DRUGS FOR CHRONIC PAIN

DRUG	DOSAGE	INDICATIONS	ADVERSE EFFECTS	COMMENTS
TRICYCLIC ANTIDEPRESSANTS				
Amitriptyline, imipramine, desipramine, nortriptyline	10-150 mg/day	Peripheral neuropathy, post-herpetic neuralgia, other types of peripheral neuropathic pain, central pain, facial pain, fibromyalgia, headache prophylaxis, irritable bowel syndrome, and chronic low back pain with or without radiculopathy	Sedation, dry mouth, confusion, weight gain, constipation, urinary retention, ataxia, cardiac conduction delay (QTc prolongation)	First-line agents for neuropathic pain and headache prophylaxis Secondary amine drugs (e.g., nortriptyline) have fewer side effects than tertiary amines (e.g., amitriptyline) Contraindicated in glaucoma
SEROTONIN-NOREPINEPHRINE REUPTAKE INHIBITORS				
Venlafaxine	75-225 mg/day	Peripheral neuropathy, headache prophylaxis	Sedation, dry mouth, constipation, ataxia, hypertension, hyperhidrosis	Dose adjustment in patients with renal dysfunction
Duloxetine	60-120 mg/day	Peripheral neuropathy, fibromyalgia	Sedation, dry mouth, constipation, hyperhidrosis	U.S. Food and Drug Administration (FDA) approved for fibromyalgia and diabetic neuropathy Contraindicated in glaucoma
ANTICONVULSANTS				
Gabapentin	600-3600 mg/day	Peripheral neuropathy, post-herpetic neuralgia, other types of peripheral neuropathic pain, central pain, pelvic pain, headache prophylaxis, radiculopathy, chronic postsurgical pain	Sedation, weight gain, dry mouth, ataxia, edema	First-line agent for neuropathic pain FDA approved for post-herpetic neuralgia Effective preemptively for postoperative pain
Pregabalin	150-600 mg/day	Peripheral neuropathy, post-herpetic neuralgia, central pain, fibromyalgia	Sedation, weight gain, dry mouth, ataxia, edema	First-line agent for neuropathic pain FDA approved for diabetic neuropathy, post-herpetic neuralgia. and fibromyalgia Effective preemptively for postoperative pain. Same mechanism of action as gabapentin
Carbamazepine	200-1600 mg/day	Facial neuralgias, diabetic neuropathy	Sedation, ataxia, diplopia, hyponatremia, agranulocytosis, diarrhea, aplastic anemia, hepatotoxicity, Stevens-Johnson syndrome	First-line agent and FDA approved for trigeminal & glossopharyngeal neuralgia Contraindicated in patients with porphyria and atrioventricular conduction block
Topiramate	50-400 mg/day	Headache prophylaxis, chronic low back pain with or without radiculopathy	Sedation, ataxia, diplopia, weight loss, diarrhea, metabolic acidosis, kidney stones	First-line agent and FDA approved for migraine prophylaxis Often used as appetite suppressant
CORTICOSTEROIDS (SYSTEMIC)				
	5-60 mg/day (prednisone)	Inflammatory arthritis, other inflammatory pain conditions (e.g., inflammatory bowel disease), traumatic nerve injury, complex regional pain syndrome	Myriad psychiatric, gastrointestinal, neurologic, and cardiac side effects; immunosuppression, weakness, edema, weight gain, elevated glucose, poor wound healing, others	Stronger evidence supports local (i.e., injection) administration More effective for acute pain Strong anti-inflammatory effects
MISCELLANEOUS				
Muscle relaxants	Variable, depending on drug	Skeletal muscle spasm, acute spinal pain, temporomandibular disorder Baclofen effective for spasticity, dystonia, and trigeminal neuralgia	Sedation, ataxia, blurred vision, confusion, asthenia, xerostomia and other gastrointestinal effects, palpitations	First-line agents for acute back pain and skeletal muscle spasm
Lidocaine patch	1-3 patches every 12 hours	Post-herpetic neuropathy, peripheral neuropathy, other types of neuropathic and possibly myofascial pain associated with allodynia	Minimal systemic side effects when applied appropriately	Second-line agent and FDA approved for post-herpetic neuralgia
Capsaicin cream	0.025% applied 3 or 4 times per day	Post-herpetic neuralgia, peripheral neuropathy and other types of neuropathic pain, chronic postsurgical pain, arthritis and other musculoskeletal conditions	Burning on application Minimal systemic side effects when applied appropriately	FDA approved for arthritis Second-line agent for post-herpetic neuralgia and third-line agent for peripheral neuropathy
Cannabinoids	Variable, depending on drug and delivery route	Strongest evidence is for multiple sclerosis May be effective for peripheral neuropathy and other types of neuropathic pain and spasticity	Myriad psychiatric, neurologic and cardiac effects; xerostomia, abdominal pain, and other gastrointestinal effects	Fourth-line agent with narrow therapeutic index Modest analgesic effect comparable to codeine

pain relief, in clinical practice, two or more drugs are often used in combination. The rational use of polypharmacy should include drugs that act at different sites in the pain signaling process or modulate different neurotransmitter systems and ideally have antagonistic adverse effects (e.g., sedation and stimulation) (Fig. 30-3). For gabapentinoids, controlled trials suggest that combination therapy with either opioids or TCAs may be more effective than either drug alone.[■■] For antidepressants, controlled studies have failed to establish a benefit for combination therapy with opioids. In a placebo-controlled crossover study performed in a population with chronic low back pain, treatment with pregabalin and celecoxib was found to be superior to monotherapy.[■]

Psychological Treatment

The relationship between pain and psychopathology is complex. The lifetime prevalence of coexisting psychiatric illness in chronic pain patients

TABLE 30-5 FORMULATIONS, DOSAGES, AND PHARMACOLOGIC INFORMATION ON COMMONLY PRESCRIBED OPIOIDS

DRUG	EQUIANALGESIC DOSAGE (ORAL UNLESS SPECIFIED)	READILY AVAILABLE ROUTES OF ADMINISTRATION	DURATION OF ACTION	COMMENTS
PURE OPIOID AGONISTS				
Morphine	30 mg	IV, IM, PO, PR SR formulation	3-6 hr for short-acting 8-12 hr for SR	Reference standard for all opioids Renally excreted active metabolite
Oxycodone	20 mg	PO, PR SR formulation	3-6 hr for short-acting 8-12 hr for SR	Widely available in combination form with nonopioid analgesics Greater euphoric effects than morphine Both IR and SR forms popular among recreational users
Hydromorphone	3-6 mg	PO, PR, IV, IM SR formulation	3-6 hr 18-24 hr for SR	Higher PO : IV conversion ratio than other opioids SR form reserved for opioid-tolerant patients, and contraindicated in patients with recent monoamine oxidase inhibitor use
Hydrocodone	30-60 mg	PO SR formulation under development	3-6 hr 8-12 hr for SR	Wide variation in morphine-equivalent dose Most commonly prescribed opioid in the United States; typically used in combination form with nonopioid analgesic acetaminophen Formulations containing <15 mg hydrocodone are schedule III in the United States SR form being tested with and without acetaminophen
Oxymorphone	10mg	PO, IV, IM, Pr; SR formulation	4-8 hr, 12 hr for SR	Co-ingestion of alcohol with SR formulation can lead to "dose-dumping", or very high plasma levels and overdose. Very low (10%) oral bioavailability. Longer duration of action than morphine or oxycodone.
Methadone	2-20 mg	PO, PR, IV	6-12 hr for pain	Morphine:methadone conversion varies according to dose and length of opioid use, ranging from 2 : 1 to >20 : 1 in patients receiving very high doses Any physician with a schedule II DEA license may prescribe for pain May take 5-7 days to reach steady state because of extended half-life (i.e., accumulation) Electrocardiographic monitoring recommended with higher doses Other properties, such as NMDA receptor antagonism and reuptake inhibition of serotonin and norepinephrine, may slow the development of tolerance and increase efficacy for neuropathic pain
Fentanyl	12.5 µg/hr (TD) 800-1000 µg (TM) 200-400 µg (B)	TD, TM, B	72 hr for TD 1.5-3 hr for TM and B	TD, TM, and B formulations may be useful in patients with poor bowel function TD: Wide variation in conversion ratios; delivery system may be associated with fewer gastrointestinal side effects TM and B: delivery systems associated with more rapid (10 min) onset than IR oral opioids U.S. Food and Drug Administration approved for breakthrough cancer pain in opioid-tolerant patients
Codeine	200 mg	PO, PR, IM SR codeine combination products available as cough suppressant	3-6 hr 12 hr for SR	Often used in combination with nonopioid analgesics Efficacy and side effects may be affected by rate of metabolism to active metabolite morphine, which varies significantly Popular as cough suppressant
Propoxyphene	200 mg	PO, PR	3-6 hr	Wide variation in morphine-equivalent dose Often used in combination form with nonopioid analgesic Toxic metabolite may accumulate with excessive use, especially in elderly Weak antagonist at NMDA receptor
Meperidine	300 mg	PO, PR, IM, IV	2-4 hr	Toxic metabolite may accumulate with excessive use, especially in patients with renal insufficiency Associated with tachycardia and hypertension Concurrent use with monoamine oxidase inhibitors may result in fatal reactions May cause more "euphoria" than other opioids IM absorption erratic and injections painful
AGONIST-ANTAGONISTS, PARTIAL AGONISTS				
Buprenorphine Buprenorphine/ Naloxone (Suboxone) (4 : 1 ratio of buprenorphine to naloxone)	0.3-24 mg SL 5-70 µg/hr (TD) 2-24 mg/day	SL, PR, IV, TD	6-8 hr 7 days for SR	Partial µ-agonist and κ-antagonist that may precipitate withdrawal in opioid-dependent patients receiving high doses Lower abuse potential and fewer psychomimetic effects than pure agonists Not readily reversed by naloxone Schedule III drug in the United States Primary use of SL preparation is to treat addiction Used in combination with naloxone (Suboxone, Subutex) for opioid dependence May prolong QT interval
Butorphanol	1 mg/ spray, repeat after 60-90 minutes (NS) 1-2 mg (IV or IM)	NS, IM, IV, PO	3-4 hr	Partial agonist and antagonist at µ-receptor and antagonist at κ-receptor Commonly used as nasal spray to treat migraine headache and less commonly for labor pain Significant abuse potential
Nalbuphine	1 : 1 parenteral ratio	SC, IM, IV	3-6 hr	Mixed agonist-antagonist, often used for labor and delivery Sometimes used to treat refractory opioid-induced pruritus
Levorphanol	4 mg	PO, IM, IV	4-8 hr	2 : 1 oral to IV conversion ratio Multiple mechanisms of action including inhibition of serotonin and norepinephrine reuptake, NDMA receptor antagonism, and σ-receptor agonism

TABLE 30-5 FORMULATIONS, DOSAGES, AND PHARMACOLOGIC INFORMATION ON COMMONLY PRESCRIBED OPIOIDS—cont'd

DRUG	EQUIANALGESIC DOSAGE (ORAL UNLESS SPECIFIED)	READILY AVAILABLE ROUTES OF ADMINISTRATION	DURATION OF ACTION	COMMENTS
Pentazocine Pentazocine/ naloxone (Talwin) (100 : 1 ratio of pentazocine to naloxone)	90 mg	PO, SC, IM, IV	3-4 hr parenteral 8 hr PO	Mixed agonist-antagonist Naloxone added in 1970s to prevent abuse Also prescribed in preparation with acetaminophen
WEAK, DUAL-ACTION OPIOID AGONISTS				
Tramadol	150-300 mg	PO	4-6 hr 24 hr for SR	Dual action involves inhibition of serotonin and norepinephrine reuptake Affinity for μ-opioid receptor 6000× less than morphine Reduced side effects compared with morphine Analogue of codeine with active metabolite in which differences in metabolism may affect analgesia and side effects Available in combination form with acetaminophen Avoid concomitant use of serotonergic drugs Maximum recommended dose of 400 mg/day Not a federally controlled substance in the United States, although certain states have classified it as schedule IV
Tapentadol	75-110 mg	PO	4-6 hr 12 hr for SR	Dual action involves inhibition of norepinephrine reuptake May have fewer of certain side effects than morphine, such as gastrointestinal and respiratory depression Maximum dose 600 mg/day Avoid concurrent use of monoamine oxidase inhibitors

B = buccal; IM = intramuscular; IR = immediate release; IV = intravenous; NMDA = *N*-methyl-D-aspartate; NS = nasal spray; PO = oral; PR = rectal; SL = sublingual; SR = sustained release; TD = transdermal; TM = transmucosal.

ranges from 50% to more than 80%. Between 30% and 60% of chronic pain sufferers experience symptoms of depression, making it the most common comorbidity. For anxiety disorders and substance abuse, co-prevalence rates are around 30% and 10 to 15%, respectively.

Viewed from a different perspective, the relationship is even more striking. More than 60% of patients with major depression and more than half of all patients with anxiety and substance abuse disorders experience chronic pain. Although it is widely acknowledged that chronic pain can predispose patients to depression, anxiety, and self-destructive behaviors such as substance abuse and suicide, what is less commonly appreciated is the effect that preexisting psychiatric conditions have on pain perception. There is a plethora of literature demonstrating that coexisting psychopathology is a strong predictor for the development of chronic pain after an acute, traumatic event (e.g., back pain episode, surgery) and is associated with poorer treatment outcomes.

It is incumbent on practitioners to screen all pain patients for psychological conditions that can adversely affect treatment (Table 30-6). Not only major psychiatric conditions, such as depression and generalized anxiety, but also maladaptive behaviors and secondary diagnoses, such as somatization disorder and poor coping skills, can negatively influence treatment.

Relaxation techniques such as biofeedback, self-hypnosis, and guided imagery have proved effective in a wide array of acute and chronic pain conditions but may be especially useful in those with high levels of anxiety. Cognitive-behavioral therapy is a highly structured form of psychotherapy predicated on the replacement of negative thought patterns and behaviors with more constructive ones. These therapies enhance modulation of pain signals and can also be effective for commonly associated symptoms such as fatigue and sleep abnormalities. Ideal candidates include educated, motivated patients in whom distorted thinking (e.g., catastrophization) and counterproductive behaviors serve to amplify pain behavior. In patients with personality disorders and ingrained maladaptive behaviors, long-term psychotherapy may be necessary.

Interventional Therapies: Nerve Blocks, Neuromodulation, and Surgery

Nerve Blocks

Injections may be performed for therapeutic, diagnostic, and sometimes prognostic purposes. Mechanistically, injections performed with local anesthetic may work by releasing entrapped nerves, enhancing blood flow, and interrupting processes involved in central sensitization (i.e., "breaking the cycle of pain"). Additional benefits of adding corticosteroid to local anesthetic include blocking the inflammatory cascade, suppressing ectopic discharges from injured nerves, and inhibiting the synthesis of prostaglandins, some of which serve to sensitize nociceptors.

Nerve blocks are almost never a panacea for noncancer pain but in appropriate candidates may provide intermediate-term pain relief, facilitate rehabilitative therapy, and improve quality of life for several weeks to months. Translating this relief into long-term improvement necessitates addressing the underlying causes and predisposing factors, which often entails psychotherapy and rehabilitation. Injections that can afford benefit in well-selected individuals include trigger point injections with local anesthetic for myofascial pain, intra-articular injection of steroids or viscosupplementation for chronic osteoarthritis, and nerve blocks with corticosteroid for entrapment syndromes (e.g., carpal tunnel syndrome). Among spinal injections, the strongest evidence is for epidural steroid injections in patients with radicular pain less than 6 months in duration, and radiofrequency denervation for facet joint pain. Neuroablative procedures such as celiac plexus neurolysis have been shown to provide significant pain relief lasting several months in patients with pain associated with upper abdominal cancers.

Electrical Stimulation

Electrical stimulation in various forms has been used for millennia to treat pain. The most commonly used type of electrical stimulation is transcutaneous electrical nerve stimulations (TENS), in which an electrical current is used to stimulate nerves for therapeutic purposes. The evidence supporting TENS to treat chronic pain is mixed, with one of the main criticisms being that any benefit is short-lasting. Spinal cord stimulation is a minimally invasive neuromodulatory technique for managing neuropathic pain states refractory to conservative measures in which an electrode(s) is inserted into the epidural space to stimulate the dorsal column. It was developed based on the gate-control theory, which postulates that activation of peripheral sensory A-fibers can attenuate pain signaling by slower-conducting pain C-fibers. Common indications include failed back surgery syndrome, complex regional pain syndrome, and outside of the United States, ischemic pain associated with peripheral vascular disease or angina. In patients with intractable chronic pain unresponsive to conservative measures, brain stimulation techniques have also shown promise. Deep brain stimulation has been demonstrated in uncontrolled studies to provide benefit for chronic neuropathic and nociceptive pain conditions, including phantom limb pain and cluster headache, whereas motor cortex stimulation has been successfully employed for trigeminal neuralgia and central pain.

Surgery

Surgical interventions are often advocated in chronic pain patients who have failed to respond to more conservative measures. A traumatic neuroma is an inexorable consequence of cutting or burning of a nerve, formed as a result of unregulated and disorganized nerve regeneration. Neuromas have been shown to fire ectopic pain signals and are often quite painful. Hence, neurolytic procedures are rarely successful in the long-term treatment of neuropathic

TABLE 30-6 PSYCHOSOCIAL FACTORS ASSOCIATED WITH CHRONIC PAIN

Multiple pain complaints
Poor job satisfaction, low pay
Inadequate coping skills
Fear-avoidance behavior
Manual labor, physically stressful job
Obesity
Somatization
Smoking
Low baseline activity levels
Ongoing litigation
Older age
Low education level
Higher presenting pain intensity, disability
Neurological symptoms
Anxiety
Depressed mood
Emotional distress

TABLE 30-7 EVIDENCE FOR TREATMENTS OF DIFFERENT CAUSES OF CHRONIC LOW BACK PAIN

CONDITION	PREVALENCE	TREATMENT
Lumbosacral radiculopathy from herniated disc	Annual prevalence 5-15%	Moderate evidence that epidural steroids may provide short-term relief, weak evidence for long-term benefit Weak evidence for percutaneous intradiscal procedures except chymopapain (strong evidence for a modest effect) Strong evidence that surgery may provide benefit for up to 2 years, but conflicting evidence for long-term benefit Negative or weak evidence for pharmacologic treatment
Spinal stenosis	5-10% of adults ≥ 65 years Rare in patients < 50 years	Moderate evidence that epidural steroids may provide short-term relief, weak evidence for long-term benefit Weak evidence for percutaneous therapy Strong evidence that surgery may provide benefit for at least 2 years Negative or weak evidence for pharmacologic treatment
Discogenic pain from degenerative disc disease	20-40% of patients with axial low back pain	Weak, conflicting evidence for modest short-term benefit with intradiscal treatments Weak, conflicting evidence that surgery may provide modest benefit for up to 2 years compared with no or unstructured treatment and that surgery is not more effective than structured care to include exercise and cognitive-behavioral treatment Negative evidence for epidural steroids
Facet arthropathy	10-15% of patients with axial low back pain, increasing with age	Moderate evidence for benefit with radiofrequency denervation Negative evidence for steroid injections and surgery
Sacroiliac joint pain	15-30% of patients with axial low back pain below L5 vertebra, increasing with age and inflammatory arthritis	Moderate evidence for short-term relief with steroid injections Moderate evidence for benefit with radiofrequency denervation Negative evidence for surgery
Myofascial pain	20%, but may be superimposed on a primary cause in more than 75% of patients	Strong evidence for exercise, muscle relaxants, and NSAIDs Weak, conflicting evidence for antidepressants Pharmacologic treatment more effective for acute than chronic low back pain
Vertebral fracture	6-18%, increasing with age and in certain ethnic groups (e.g., Asian women)	Conflicting evidence for vertebral augmentation Moderate extrapolated evidence for NSAIDs, although concerns exist for effect on bone healing Strong evidence for arthroses and bisphosphonates Anecdotal evidence for surgery, which may be necessary for stabilization Facet pain may play a role in pain after vertebral fracture

NSAIDs = nonsteroidal anti-inflammatory drugs.

pain. Part of the challenge in deciding when operative therapy is indicated revolves around the difficulty involved in establishing a causative relationship between the targeted pathologic process and pain. Roughly 10% of women of reproductive age have endometriosis (Chapter 236), but many patients with endometriosis have minimal symptoms, and pelvic pain is a frequent occurrence in young women with no detectable disease. With respect to inguinal hernia repair and spinal decompression, the incidence of chronic postsurgical pain is inversely correlated with the size of the bowel and disc herniation, respectively. This illustrates that in many individuals, the targeted disease may not be the primary cause of symptoms. On a similar note, scar tissue is a predictable sequela of surgical treatment, but lysis of adhesions is only infrequently associated with long-term symptom palliation because of the high recurrence rate and absence of any means to correlate the presence of adhesions with pain. Not surprisingly, surgery performed solely to remove a painful body part (e.g., hysterectomy, orchiectomy) rarely results in long-term benefit.

Back Pain

Back pain (Chapter 400) is the leading cause of disability in people younger than 45 years in the world. In patients who present with serious spinal disease (tumor, trauma), decompression, stabilization and fusion can be beneficial, but outcomes are strongly dependent on patient selection. Randomized studies have determined that decompression procedures done for radiculopathy and spinal stenosis are effective for short-term pain relief, but most demonstrate no long-term (>2 years) improvement compared with conservative treatment. With respect to fusion or disc replacement performed for mechanical pain associated with common degenerative changes, randomized trials suggest that less than one third of patients can expect significant pain relief or a highly functional outcome, with the results diminishing over time (Table 30-7).

Physical Treatments

The use of "physical" therapies to provide pain relief and to enhance function is a cornerstone in the multimodal approach to the patient with pain. Physical therapists evaluate, educate, and provide minimally invasive procedural interventions to help prevent and alleviate pain and dysfunction. These include addressing causative mechanisms of pain (e.g., correcting gait abnormalities) and providing treatments (e.g., hot and cold packs, joint manipulation).

Exercise has been used for decades as a treatment for chronic pain and a means to prevent injury. Exercise works through a variety of mechanisms, including enhancing blood flow, releasing endorphins, exerting anti-inflammatory effects, activating inhibitory pathways, and improving sleep and mood. Whereas the largest body of research has been conducted for spinal pain, benefits have also been demonstrated in fibromyalgia, headaches, arthritis, neuropathic pain, and cancer.

Complementary and Alternative Therapies

Patients are seeking complementary and alternative medical (CAM) treatments (Chapter 39) with increasing frequency, with utilization rates around 40%. Pain is the most common indication for CAM therapies. Some of the most popular CAM modalities are acupuncture, chiropractic, and yoga, all of which have been shown to be beneficial in certain contexts. However, the effect size tends to be modest for these treatments, and there is little evidence to support one modality over another or against conventional medical treatments.

Pain Management in Older Persons

Older adults are more likely to report pain than are younger cohorts and often present with multiple comorbidities. The increased risk for drug-related adverse effects in this population is the basis for the popular recommendation "start low and go slow" in the titration of analgesic drugs. Age-related physiologic factors that can decrease the therapeutic dose of opioid and nonopioid analgesics include changes in volume of distribution and protein binding, decreased metabolism, decreased excretion, and increased pharmacologic sensitivity. For these reasons, nonpharmacologic interventions, such as ergonomic modifications, tailored physical therapy and exercise programs, nutritional consultation, psychobehavioral approaches, and injections, should be considered in appropriate patients.[14]

FUTURE DRUGS AND PREVENTION OF PAIN

Much research is being devoted to development of new routes of drug administration (e.g., transdermal, transmucosal), abuse-deterrent opioids, and novel nonopioid drug treatments, which can optimize outcomes and reduce risks and side effects. Two other areas receiving significant research attention involve the genotyping and phenotyping of chronic pain patients. The conceptual appeal of these endeavors is that pain treatment tailored to individuals may result in greater benefit and less harm than the shotgun approach.

Regenerative therapies, which seek to facilitate the body's ability to repair, replace, restore, or regenerate diseased or damaged tissue, are another frontier in pain medicine. Whereas many of these treatments are currently in preliminary stages of development, they may someday be used to treat central, joint,

and spinal pain. Examples that are as yet unproven include stem cell therapy and the infusion of platelet-rich plasma, which involves stimulation of the body's natural healing processes.

Another area that has been underinvestigated is identifying patients at high risk for development of pain and employing strategies either to prevent pain or to minimize disease burden. In patients at high risk for chronic postsurgical pain (e.g., young patients with preexisting pain and psychological comorbidities), these measures might include the use of preemptive analgesics such as NSAIDs, anticonvulsants, and cytokine inhibitors and employing surgical techniques associated with less trauma. For patients with musculoskeletal complaints, this might entail educational initiatives and extensive rehabilitation.

Finally, the specialty of pain medicine must come to terms with the reality of spiraling health care costs by developing cost-effectiveness models by which to gauge benefit. Clinical trials evaluating new treatments should measure not only subjective outcomes such as pain scores but also objective ones that can result in societal cost savings, such as return to work or prevention of surgery. Proving that new treatments are more effective than existing or placebo treatments and result in cost-containment should be a cornerstone of future clinical research.

REVIEW QUESTIONS

1. Which one of the following describes central neuropathic pain?

A. A type of nociceptive pain
B. Most often seen after a stroke
C. A major cause of the pain of irritable bowel syndrome
D. Almost never genetic in etiology
E. Usually not responsive to anticonvulsants like gabapentin and pregabalin

Answer: B The most common overall cause of central pain is central post-stroke pain, occurring after about 8% of cerebrovascular accidents. Central pain and peripheral pain are the two major types of "neuropathic pain," whereas "nociceptive pain" usually results from an injury or disease affecting somatic structures like skin, muscle, tendons, bone, joints, and ligaments. The pain of irritable bowel syndrome is one of the visceral forms of nociceptive pain (see Table 30-1). Gabapentin and pregabalin are considered first-line therapies for central neuropathic pain (see Table 30-3). Heritability is a component of practically all types of pain, including central neuropathic pain, estimated to account for between 30 and 60% of the variance in pain response (see Genetics). See Neuropathic, Nociceptive, and Mixed Pain.

2. Which of the following is true regarding diagnostic testing for pain?

A. Imaging has little if any role in diagnosing the cause of pain.
B. MRI findings correlate well with the intensity of spinal pain.
C. Early imaging for back pain guides decision making and improves outcomes.
D. Normal neurophysiologic (EMG, nerve conduction) test results are useful to rule out a neuropathic etiology of pain.
E. MRI is ideal for discerning inflammation and soft tissue pathology as causes of pain.

Answer: E For nonspinal pain conditions, MRI is ideal for identifying inflammation and soft tissue pathology. (In contrast, CT scanning may be better for detecting bleeding and bone pathology as causes of pain.) There is poor correlation, however, between MRI findings and the intensity of spinal pain, with more than 50% of asymptomatic individuals having abnormalities on lumbar, thoracic, and cervical views. Systematic reviews have found that early imaging for back pain does not improve outcomes or affect decision making and should be reserved for those individuals with indications of a serious underlying condition (see reference A1). EMG and nerve conduction studies are associated with significant false-negative rates and are not sensitive in detecting impairment of small fiber conduction; therefore, normal results do not rule out neuropathic pain. See Diagnostic Tests.

3. Which of the following statements is true regarding opioid analgesics?

A. Most opioids are devoid of end-organ toxicity.
B. Opioids are comparably effective for long-term pain relief in cancer and noncancer patients.
C. Opioids delivered by patient-controlled analgesia (PCA) require intensive supervision.
D. Most patients on opioid therapy for chronic pain become addicted and/or abuse their drug.
E. Opioids are cleared primarily by the liver, not the kidneys.

Answer: A Most opioids are not associated with end-organ toxicity, with the notable exception being meperidine. Abuse of drugs and addiction are potentially serious complications of long-term opioid use but are estimated to occur in only 20% and 10% of such individuals, respectively. Morphine is one of the opioids eliminated predominantly by the kidneys and should be used with caution in patients with renal dysfunction. Opioid analgesics are the cornerstone of treatment for cancer pain. In contrast, several recent reviews and guidelines have concluded that they provide long-term improvement in only a minority of individuals with noncancer pain conditions (see reference A10). PCA devices are safe; are programmed with basal infusion, bolus dose, lockout interval, and maximum dose per hour controls; and allow patients to control their pain management with less dependence on health care providers. See Opioid Analgesics.

BIOLOGY OF ADDICTION

ERIC J. NESTLER AND STEVEN E. HYMAN

DEFINITION

Drug addiction is compulsive substance use despite serious negative consequences. Harmful drug use and addiction are significant contributors to medical morbidity and mortality both directly as a result of the toxic effects of abused drugs and indirectly through accidents, violence, nonsterile needle use, smoking, and other health hazards. By far the greatest contributors to illness and death are the widely used legal drugs, tobacco (Chapter 32), and alcohol (Chapter 33), although illegal addictive drugs and abused prescription drugs also exact a significant toll. In addition, addiction creates enormous burdens on society by impairing the function of the addicted person in multiple life roles, disrupting families and neighborhoods, and motivating crime. Globally, drug use is not distributed evenly and is not simply related to stringency of drug policy.[1]

Compulsive use, the cardinal feature of addiction, means that the affected person cannot control substance use for a significant time despite powerful reasons to do so, such as drug-related health problems, drug-associated arrests, or the threat of losing one's job or spouse. In the clinic, addiction can be remarkably frustrating to treat: drug seeking and administration are apparently voluntary behaviors that an otherwise sentient person seems unwilling to control. Even after significant efforts have been exerted to get an addicted patient into drug treatment, relapse is common, even long after the last withdrawal symptom has cleared. Relapses are often precipitated by stress or by reminders of drug use (cues) that may range from familiar drug use contexts (such as smoking after a meal) to interactions with drug-using friends, the smell of marijuana or tobacco smoke, and body feelings previously associated with drug seeking (so-called interoceptive cues). Molecular, cellular, and behavioral studies of drug action in animal models and noninvasive human neuroimaging studies are providing significant insights into the neurobiology underlying compulsive drug taking and its persistence. Other important frontiers of research include the human genetics of addiction risk and more recently, the neurobiology of what have been called behavioral addictions, such as compulsive gambling.

Drug users may repeatedly take drugs to gain pleasure or to escape from negative feelings, including the aversive feelings that may occur when drugs wear off. As a result of repeated drug administration over time, initial protein targets for the drugs and their downstream signaling pathways (Table 31-1) are excessively stimulated and may thus undergo homeostatic adaptations. These adaptations can produce tolerance (the need for increasing drug doses to achieve desired affects) or dependence (revealed by withdrawal symptoms between drug doses or with drug cessation). Both tolerance and dependence can contribute to ongoing drug use and to dosage increases; however, neither tolerance nor dependence alone explains compulsive use. First, tolerance and dependence occur not only with repeated use of many addictive drugs (e.g., heroin) but also with many nonaddictive drugs (e.g., β-adrenergic antagonists [propranolol], α_2-adrenergic agonist antihypertensive agents [clonidine], nitrates, selective serotonin reuptake inhibitor antidepressants). Second, some highly addictive drugs, such as cocaine, may produce little physical dependence and withdrawal in some individuals who nonetheless exhibit compulsive use. Finally, if dependence and withdrawal were necessary factors in addiction, the phenomenon of late, post-detoxification relapse would not be the major clinical problem that it is.[2] Although these forms of homeostatic adaptation play a role in addiction, as will be described, other types of plasticity within the nervous system are more significant.

RISK FACTORS FOR ADDICTION

Only a minority of individuals who use drugs go on to become addicted. The best-established risk factors for addiction are male sex and family history. Across countries and cultures, males have a greater risk for both heavy drug use and addiction, with risk ratios in the range of 1.4 : 1 to 2 : 1. In recent years, however, the sex ratios have narrowed in many countries, especially for tobacco use and alcohol. Moreover, females who succumb to addiction tend to do so more quickly after initial drug exposures, and drug use during pregnancy can have enormous deleterious effects on the fetus.

Genes play the preponderant role in familial risk as evidenced by twin and adoption studies.[3,4] Twin studies consistently show higher rates of concordance for heavy drug use and addiction within monozygotic twin pairs than within dizygotic twin pairs. Adoption studies that have been performed in several Scandinavian countries and in the United States have focused mostly on alcoholism. These studies demonstrate that individuals adopted early in life tend to resemble their biologic rather than their adoptive parents with respect to patterns of alcohol use. Large population genetic studies suggest that the heritable risk for addiction to any of several substances, including opiates, stimulants, nicotine, alcohol, and marijuana, is roughly the same and varies between 20 and 60%, depending on the study.

Although genes clearly play a significant role in vulnerability to addiction, few of the specific genetic variants that confer risk have been identified with certainty. Like all common neuropsychiatric disorders, addiction risk is highly

TABLE 31-1 PROPERTIES OF ADDICTIVE DRUGS

DRUG	NEUROTRANSMITTER	DRUG TARGET	EFFECT AFTER BINDING
Opiates (morphine, heroin, oxycodone)	Endorphins; enkephalins	μ and δ opioid receptor (agonist)	Activate G_i/G_o; activate K^+ channels
Psychostimulants (cocaine, amphetamines)	Dopamine (DA)	Dopamine transporter (DAT)* (antagonist)	Increase synaptic DA; stimulate presynaptic and postsynaptic DA receptors
Nicotine	Acetylcholine	Nicotinic acetylcholine receptor (nAChR) (agonist)	Stimulate cation channel (may desensitize)
Alcohol	γ-Aminobutyric acid (GABA) Glutamate	$GABA_A$ receptor (agonist) *N*-methyl-D-aspartate (NMDA) receptor (antagonist)	Activate Cl^- channel Inhibit Ca^{2+} entry
Marijuana (Δ^9-tetrahydrocannabinol)	Anandamide; 2-arachidonoylglycerol	Cannabinoid CB_1 (agonist)	Activate G_i/G_o; activate K^+ channels
Phencyclidine, ketamine		NMDA receptor (antagonist)	Inhibit Ca^{2+} entry

*The psychostimulants also interact with the norepinephrine and serotonin transporters, but under normal conditions, it is the DAT that is critical for rewarding and addictive properties. Unlike cocaine, amphetamines enter dopamine nerve terminals through the DAT and interact with a second target, the vesicular monoamine transporter (VMAT), to release DA into the cytoplasm and thence, through the DAT, to release it into the synapse.

Modified from Hyman SE, Malenka RC, Nestler EJ. Neural mechanisms of addiction: the role of reward-related learning and memory. *Annu Rev Neurosci.* 2006;29:565-598.

genetically complex; there is evidence from linkage and association studies for contributions by a large number of genetic variants of relatively small effect. Large genome-wide association studies and other applications of modern genomic methods are continuing. However, the task of gene identification is also complicated by the challenges of phenotype definition. There are no objective medical tests with which to make the diagnosis, and there may be independent genetic and nongenetic risk factors for different stages of substance use disorders, such as drug experimentation, addiction, and treatment responsiveness. Moreover, twin and family studies suggest that there may be both shared and unshared genetic risk factors underlying addictions to different drugs. As in other genetically complex disorders, it is hoped that with the identification of multiple risk-conferring variants, it will be possible to identify biochemical pathways involved in addiction pathogenesis, which will then suggest potential targets for new and more effective treatments.

REWARD CIRCUITRY: THE NEURAL SUBSTRATE OF ADDICTION

The survival and perpetuation of species require that animals, including humans, learn to predict threats and also learn the circumstances under which they can obtain "rewards," such as food, water, shelter, and opportunities for mating. A simple operational definition of reward is a stimulus that elicits approach and consummatory behaviors. Several interconnected neural circuits, highly conserved in evolution, control an individual's responses to rewarding and aversive stimuli (Fig. 31-1). Dopamine-releasing neurons in the ventral tegmental area (VTA) of the midbrain and their major target neurons in the nucleus accumbens (NAc) in the ventral striatum serve as a rheostat that detects and drives responses to rewards and threats, the amygdala and hippocampus are crucial for forming reward- and fear-related memories, the dorsal striatum (caudate and putamen) mediates well-learned behaviors and habits, and several regions of prefrontal cortex exert executive control over these subcortical systems. Addiction involves abnormal functioning of this entire circuit.[5]

The neurotransmitter dopamine, released from VTA nerve terminals in the NAc, plays the key (albeit not the only) role in binding rewards and reward-associated cues to adaptive reward-seeking responses. In animals, implanted electrodes can record firing of dopamine neurons; microdialysis catheters and electrochemical methods can be used to detect dopamine that has been released from presynaptic terminals. In humans, positron emission tomography permits indirect measures of dopamine release by observing the displacement of a positron-emitting D_2 dopamine receptor ligand previously bound to receptors after a stimulus or pharmacologic challenge. By use of such methods in multiple paradigms, it has been well established that natural rewards cause firing of VTA neurons and dopamine release in the NAc and other forebrain regions. When dopamine action is blocked, whether by lesioning of dopamine neurons, blocking of postsynaptic dopamine receptors, or inhibition of dopamine synthesis, rewards no longer motivate the behaviors necessary to obtain them.

New insights into the role of dopamine have emerged from studies of patients with Parkinson disease (Chapter 409). Parkinson disease results from the death of midbrain dopamine neurons; however, neurons within the substantia nigra, which project to the dorsal striatum, are more severely affected than neurons within the VTA. Patients are generally treated with

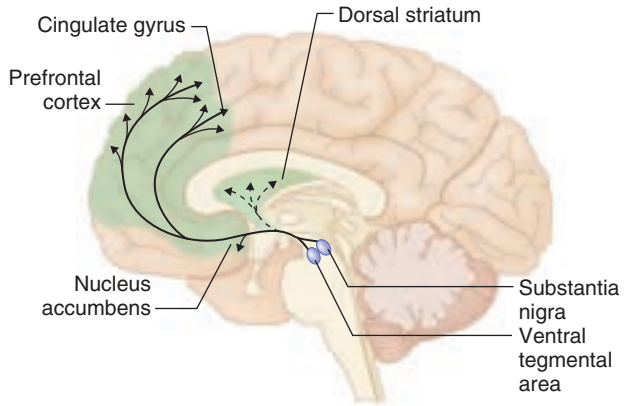

FIGURE 31-1. Brain reward circuits. The major dopaminergic projections to the forebrain that underlie brain reward are shown superimposed on a diagram of the human brain: projections from the ventral tegmental area to the nucleus accumbens, amygdala (not shown), hippocampus (not shown), and prefrontal cerebral cortex. Also shown are projections from the substantia nigra to the dorsal striatum (caudate and putamen and related structures) that play a role in habit formation and other deeply ingrained motor behaviors, including those related to drug consumption. (From Hyman SE, Malenka RC, Nestler EJ. Neural mechanisms of addiction: the role of reward-related learning and memory. *Annu Rev Neurosci.* 2006;29:565-598.)

L-dopa, a dopamine precursor, but as the disease progresses, other drugs may be needed, including selective D_2 dopamine receptor agonists. Relevant to this discussion is that a minority of patients treated with D_2 dopamine receptor agonists develop new risky, goal-directed behaviors, such as compulsive gambling or shopping. These behaviors generally cease when the drug is withdrawn. It is thought that whereas dopamine receptor agonists produce therapeutic effects on motor behavior in the more fully denervated dorsal striatum, they can combine with endogenous dopamine from preserved VTA neurons to overstimulate the NAc and other components of reward circuitry. These observations not only underscore the role of dopamine in motivation and reward seeking but also suggest that what have been called behavioral addictions share neural substrates with drug addiction.[6]

Much evidence suggests that the precise pattern of dopamine neuron firing and the resulting synaptic release of dopamine in forebrain circuits act to shape behavior so as to maximize future reward. In a basal state, dopamine neurons have a slow tonic pattern of firing. When a reward is encountered that is new, unexpected, or greater than expected, there is a phasic burst of firing of dopamine neurons causing a transient increase in synaptic dopamine. When a reward is predicted from known cues and is exactly as expected, there is little change from the tonic pattern of firing, that is, only small additional dopamine release. When a predicted reward is omitted or less than expected, dopamine neurons pause their firing to levels below their tonic rate. Phasic increases in synaptic dopamine signify that the world is better than expected, facilitate learning of new predictive information, and bind the newly learned predictive cues to action.

Dopamine is not the only neurotransmitter that signals reward. Others, including acetylcholine, endogenous opioid peptides (e.g., enkephalin and

endorphin), and endogenous lipid substances called endocannabinoids (because cannabinoid drugs like marijuana are agonists at their receptors), are also released in the reward circuitry in response to natural rewards.

PROPERTIES OF ADDICTIVE DRUGS

Addictive drugs are chemically diverse and interact with different molecular targets in the nervous system (Table 31-1). They also exhibit significant differences from each other in many of their physiologic and behavioral effects. For example, cocaine and amphetamines are stimulants; they increase arousal, may cause anxiety, and at lower doses enhance cognitive performance. Alcohol is a depressant, is anxiolytic at low doses, and degrades cognitive performance. Heroin and other opiates are analgesic and cause drowsiness, constipation, and pupillary constriction. The shared behavioral effect of all addictive drugs is the liability, in vulnerable individuals, of causing compulsive use. The shared pharmacologic property that is required to cause addiction is the ability to increase levels of synaptic dopamine in the NAc and other forebrain regions. For example, cocaine blocks the dopamine uptake transporter that normally clears dopamine from synapses. Amphetamines cause reverse transport of dopamine into synapses through the dopamine uptake transporter. Opiates, nicotine, alcohol, and cannabinoids cause dopamine release, acting by different initial mechanisms to stimulate VTA dopamine neurons or to release them from resting inhibitory control. Each of these other drugs also induces reward through nondopamine mechanisms, that is, through activating cholinergic, opioid, or cannabinoid receptors within the reward circuitry (Table 31-1).

Natural rewards, such as food or sexual opportunities, regulate the firing of dopamine neurons through highly processed sensory information, both external and interoceptive. Addictive drugs short-circuit this kind of information processing by acting directly on proteins that control dopamine and other signals in the reward circuitry. Acting by such direct pharmacologic mechanisms, addictive drugs typically produce greater quantities of synaptic dopamine and other reward-related neurotransmitters over longer times than natural rewards do. In addition, addictive drugs provide a grossly pathologic learning signal by occluding pauses in dopamine and other neuron firing even when drug use proves less pleasurable than expected or even aversive. For example, when the inhalation of a smoker causes painful coughing, it might seem that the brain would signal an experience that is worse than expected with a resulting decrement in VTA neuron firing rate. However, because nicotine causes dopamine release pharmacologically, independent of the smoker's actual experience, reward circuits, unavailable to conscious introspection, still receive a positive message that reinforces nicotine seeking and nicotine use. In short, addictive drugs, by virtue of their effects on dopamine and related neurotransmitters, always signal "better than expected."

DRUG-INDUCED NEURAL PLASTICITY RELEVANT TO ADDICTION

Neurobiologic research on addiction has focused intensely on compulsive aspects of drug use, the ability of specific cues to activate drug seeking and craving, and the long persistence of stress and cue-dependent relapse risk. As described previously, compulsive drug use and the power of drug-associated cues reflect the usurpation of the brain's reward circuitry by drugs of abuse.[7] The persistence of addiction reflects long-term changes in neurons and synapses and their interacting circuits. Research during more than a decade has identified long-term changes in gene expression resulting from use of addictive drugs; recently, some long-lived alterations in gene expression have been attributed to drug-induced epigenetic mechanisms, such as modifications of chromatin.[8]

Long-term changes in gene expression may render the addicted person susceptible to stress and may also create persistent changes in hedonic state and mood regulation that may motivate drug taking. By themselves, however, changes in gene expression do not explain the ability of exquisitely specific cues to activate drug seeking or, if seeking is impeded, intense subjective drug craving. The ability of specific cues to activate drug seeking and wanting is based on long-term associative memories consolidated under the influence of dopamine and other reward signals. Long-term memory formation represents perhaps the most persistent changes in brain function that may occur in adult life. The neural substrates of memory are likely to include alterations in synaptic weights, such as long-term potentiation or long-term depression, and physical remodeling of dendritic spines. Processes of drug sensitization (or reverse tolerance), demonstrated in animal models and in humans, may contribute to these memory-related phenomena.[9]

The centrality of associative learning mechanisms for addiction was first recognized from clinical observation: much drug taking and, most notably, late relapses follow exposure to cues previously associated with drug use. Cues that can reinitiate drug use include environmental stimuli (e.g., persons with whom drugs have been used, drug paraphernalia) and body feelings. Because addictive drugs reliably increase synaptic dopamine and other reward-related neurotransmitters as a result of their direct pharmacologic actions—indeed, they produce excessive and grossly distorted reward signals—the brain receives a powerful impetus to connect the circumstances in which the drugs have been used with the motivation to take drugs again. Even if the drug is no longer pleasurable, the signals continue to reinforce drug wanting and seeking. Moreover, the certainty and magnitude of these signals give drugs a marked advantage over natural rewards and other learned goals, including prosocial activities.

In the laboratory, it has been possible to study the effects of drugs and drug cues on neural circuits, physiology, and subjective responding in addicted human subjects. For example, drug-associated cues have been shown to elicit drug urges and physiologic responses (such as sympathetic activation) as well as activation of reward circuits in addicted human subjects. By positron emission tomography, cocaine-related cues have been shown to elicit dopamine release in the dorsal striatum in addicted subjects.

Investigations at the cellular and molecular levels have begun to identify the physiologic and molecular changes that underlie the effects of addictive drugs on reward-related memory processes. Among psychotropic drugs that have been examined, only those drugs that can cause addiction produce long-term potentiation in brain reward circuits including the VTA. Addictive drugs also activate transcription factors, such as the cyclic adenosine monophosphate response element binding protein (CREB), and alter the composition of activator protein 1 (AP-1) complexes (composed of Fos and Jun families of transcription factors) in brain reward circuits. Cocaine, opiates, and other addictive drugs have been shown to regulate many genes downstream of CREB, AP-1, and other transcription factors. As well, it has been increasingly possible, through the use of genetically modified mice and virus-mediated gene transfer, to directly demonstrate the involvement of these transcriptional mechanisms in the range of behavioral abnormalities induced by repeated drug exposure in animal models. However, it is far more challenging to determine which drug-regulated proteins are causally involved in human addiction. Part of the challenge is that, whereas rodent models have provided many insights into drug action and behavior, it is difficult to model human compulsion in animals, that is, to model a free-living and independent person who loses control over drug use while experiencing the negative consequences of that use. That said, a growing body of knowledge is emerging about the neural and molecular processes that produce addiction, with the hope of translating these advances into medical diagnostic tests and more effective treatments of addictive disorders.

REVIEW QUESTIONS

1. In addition to dopamine, all of following are important mediators of reward signals in the brain EXCEPT which?

A. Acetylcholine
B. Endocannabinoids
C. Dynorphin
D. Endorphins and enkephalins

Answer: C Dynorphin, although an endogenous opioid peptide, does not activate μ (mu) and δ (delta) opioid receptors. Rather, it activates κ (kappa) opioid receptors, which mediate an aversive effect. See reference 7.

2. Which of following brain regions is NOT important in controlling responses to rewarding stimuli in the environment?

A. Amygdala
B. Occipital cortex
C. Hippocampus
D. Prefrontal cortex
E. Dorsal striatum

Answer: B All of the other brain regions listed are key components of the brain's reward circuitry. In contrast, the occipital cortex is most important for detecting and interpreting visual stimuli. See reference 7.

3. Which of the following statements best describes the activity of dopamine neurons in the ventral tegmental area in response to rewards?

A. The neurons show large increases in phasic firing in response to an unexpected reward.
B. The neurons show large increases in phasic firing in response to the withholding of an expected reward.
C. The neurons show large increases in tonic firing in response to the withholding of an expected reward.
D. The neurons show large decreases in tonic firing in response to an unexpected reward.

Answer: A Unexpected rewards induce an increase in phasic firing of the neurons. All other answers are incorrect responses. See reference 7.

4. Which of the following properties is unique to a drug of abuse?

A. It increases dopamine signaling from the ventral tegmental area to the nucleus accumbens.
B. It increases dopamine signaling from the substantia nigra to the dorsal striatum.
C. It decreases dopamine signaling from the substantia nigra to the dorsal striatum.
D. Its repeated use is associated with tolerance.
E. Its repeated use is associated with dependence and withdrawal.

Answer: A All drugs of abuse share only one property: increasing dopamine transmission from the ventral tegmental area to the nucleus accumbens. Choices B and C are incorrect. Although drugs of abuse do cause tolerance and dependence/withdrawal (choices D and E), many nonabused drugs do so as well. See reference 7.

5. Which of the following is NOT a known mechanism of a drug of abuse?

A. Cannabinoid receptor agonist
B. Nicotinic cholinergic receptor agonist
C. NMDA glutamate receptor antagonist
D. $GABA_A$ receptor agonist
E. Dopamine receptor antagonist

Answer: E All drugs of abuse increase dopamine signaling; a dopamine receptor antagonist would block some of the actions of a drug of abuse. All other answers are known mechanisms of a drug of abuse. See reference 7.

NICOTINE AND TOBACCO

TONY P. GEORGE

DEFINITIONS

Cigarette smoking is the most common (>90%) method of tobacco use, although other forms of tobacco use, including pipe tobacco, cigars, and smokeless tobacco, are common. Nicotine is the active ingredient in tobacco that acts as a reinforcer for repeated use for all forms of tobacco.

EPIDEMIOLOGY

Cigarette smoking is the most preventable cause of morbidity and mortality in the Western world. In the United States, approximately 20% of the general population currently uses tobacco compared with 47% in 1965. Since the

release of the U.S. Surgeon General's report in 1965, smoking prevalence has been substantially reduced, but this reduction appears to have slowed in recent years, likely because the remaining 20% of smokers are refractory to tobacco treatment. Approximately 450,000 people in the United States die each year as a result of smoking-attributable medical illnesses, including lung cancer, chronic obstructive pulmonary disease, cardiovascular disease, and stroke; and economic and health care costs of tobacco use exceed $400 billion annually. Smokeless tobacco (e.g., chewing tobacco) use has also increased, which has contributed to higher rates of oral pathologies, including precancerous oral lesions and cancers of the mouth and nasopharynx. Moreover, the health risks of environmental tobacco smoke (ETS) have become increasing clear, prompting the development of widespread tobacco bans in public settings.

Worldwide, it is estimated that approximately 1.1 billion people use tobacco on a regular basis, including approximately 65 million in the United States. Tobacco smoking is increasing rapidly throughout the developing world, and it is estimated that cigarette smoking will cause about 450 million deaths worldwide in the next 50 years.[1] In particular, the onset of smoking occurs at a younger age, the rates of smoking in women are increasing, and more smokers are of a lower socioeconomic status. Reducing smoking prevalence by 50% would prevent 20 to 30 million premature deaths in the first quarter of this century and 150 million in the second quarter.

For most smokers, quitting is the single most important thing they can do to improve their health.[2] A prospective cohort study in Norway suggests that even with sustained reductions (>25 to 75%) in daily smoking consumption, there is little if any decrease in cardiovascular disease and lung or other smoking-related cancer risk, further substantiating the merits of quitting versus reducing smoking.

PATHOBIOLOGY

Nicotine is the primary reinforcer in tobacco smoke, with contributions from more than 4000 components to the sensory (non-nicotine) aspects of cigarette smoking. The primary site of action of nicotine is the $\alpha_4\beta_2$ nicotinic acetylcholine receptor (nAChR), and the endogenous neurotransmitter acting on nAChRs is acetylcholine. nAChRs in the central nervous system (CNS) are pentameric ion channel complexes comprising two α- and three β-subunits; the seven α-subunits are designated α_2 to α_9 and the three β-subunits are designated β_2 to β_4. This produces considerable diversity in subunit combinations, which may explain the region-specific and functional selectivity of nicotinic effects in the CNS.[3] Activation of nAChRs leads to Na^+/Ca^{2+} ion channel fluxes and neuronal membrane depolarization. nAChRs are located presynaptically on several neurotransmitter-secreting neuron types in the CNS, including mesolimbic dopaminergic (DA) neurons that project from the ventral tegmental area (VTA) to the nucleus accumbens (NAc). Activation of nAChRs on mesolimbic DA neurons leads to DA secretion in the nucleus accumbens.

At low concentrations of nicotine, $\alpha_4\beta_2$ nAChR stimulation of afferent GABAergic projections onto mesoaccumbal DA neurons predominates, leading to reduced mesolimbic DA neuron firing and DA release. At higher nicotine concentrations, $\alpha_4\beta_2$ nAChRs desensitize, and predominant activation of α_7 nAChRs on glutamatergic projections occurs, leading to increased mesolimbic DA neuron firing and release. Within milliseconds of activation by nicotine, nAChRs desensitize. After overnight abstinence, nAChRs resensitize; this may explain why most smokers report that the first cigarette in the morning is the most satisfying. Interestingly, positron emission tomography (PET) neuroimaging studies have shown that smoking 2 or 3 puffs from a cigarette produces saturation of nAChRs in the brain reward system, suggesting that although binding to central nAChRs is an important first step in the effects of nicotine, it is not a complete explanation for continued smoking behaviors.

CLINICAL MANIFESTATIONS

Although there is a subset of cigarette smokers who do not smoke every day (e.g., "chippers"), most cigarette smokers are daily users and have some degree of physiologic dependence on nicotine. Smokers typically describe a "rush" and feelings of alertness, relaxation, and "satisfaction" when smoking, and it is well known that nicotine has both stimulating and anxiolytic effects depending on basal level of arousal. Airway stimulation is an important aspect of smoking behavior, and additives such as menthol enhance the experience by increasing the taste and reducing the harshness of smoked tobacco.

Interestingly, the positive effects of cigarette smoking (e.g., taste, satisfaction) appear to be mediated by non-nicotine components of tobacco such as tar. Besides positive reinforcement, withdrawal, and craving, there are several secondary effects of nicotine and tobacco use that may contribute to both maintenance of smoking and smoking relapse, including mood modulation (e.g., reduction of negative affect), stress reduction, and weight control. In addition, conditioned cues can elicit the urge to smoke even after prolonged periods of abstinence. Specific effects might be most relevant to smokers wishing to lose weight and to those with psychiatric presentations (mood modulation, cognitive enhancement, stress reduction). These secondary effects may present additional targets for pharmacologic intervention in certain subgroups of smokers (e.g., those with schizophrenia or depression, or those concerned about their weight).

DIAGNOSIS

The *Diagnostic and Statistical Manual*, 5th edition (DSM-5),[4] which was released in 2013 by the American Psychiatric Association, has changed the diagnostic terminology for nicotine and tobacco, eliminating the term *dependence* and instead using the term *tobacco use disorder*. Tobacco use disorder is established clinically by historical documentation of 2 of the following 11 criteria:

1. Tobacco often taken in larger amounts or over a longer period than was intended
2. Persistent desire or unsuccessful efforts to cut down or control tobacco use
3. A great deal of time spent in activities necessary to obtain or use tobacco
4. Presence of craving, or a strong desire or urge to use tobacco
5. Recurrent tobacco use resulting in failure to fulfill major obligations at work, school, or home
6. Continued tobacco use despite persistent or recurrent social or interpersonal problems caused or exacerbated by the effects of tobacco
7. Important social, occupational, or recreational activities given up or reduced because of tobacco use
8. Recurrent tobacco use in situations in which it is physically hazardous (e.g., smoking in bed)
9. Continued tobacco use despite persistent or recurrent physical or psychological problems that are caused or exacerbated by tobacco use
10. Tolerance, as defined by either a need for markedly increased amounts of tobacco to achieve desired effects, or markedly diminished effects with continued use of the same amount of tobacco
11. Withdrawal, manifested by the presence of the characteristic tobacco abstinence syndrome (e.g., four of the following: irritability, anxiety, difficulty concentrating, increased appetite, restlessness, dysphoric mood, insomnia), or tobacco (or nicotine) taken to relieve or avoid tobacco withdrawal symptoms.

For abstinent smokers, remission is classified as early (between 3 and 12 months of abstinence) or sustained (>12 months of abstinence). Moreover, current severity of tobacco use disorder is coded as mild (2 or 3 symptoms), moderate (4 or 5 symptoms) or severe (6 or more symptoms).

In addition, most physiologically dependent tobacco smokers state that they smoke their first cigarette of the day within the first 5 minutes of awakening (e.g., time to first cigarette <5 minutes after awakening). Timeline follow-back procedures and smoking diaries have been used successfully to monitor smoking consumption over time. Scales such as the Fagerstrom Test for Nicotine Dependence allow assessment of the level of nicotine dependence, with scores higher than 4 on a scale of 0 to 10 being consistent with physiologic dependence to nicotine. Nicotine craving and withdrawal can be reliably monitored using validated scales such as the Tiffany Questionnaire for Smoking Urges and the Minnesota Nicotine Withdrawal Scale. These scales have excellent test-retest reliability and internal consistency in smokers with schizophrenia compared with nonpsychiatric control smokers, suggesting that they can be used in psychiatric populations.

TREATMENT

Rx

Psychosocial Treatments

Behavioral therapies are based on the theory that learning processes operate in the development, maintenance, and cessation of smoking (Table 32-1). Behavioral treatments for smoking can facilitate motivation to quit, provide an emphasis on the social and contextual aspects of smoking, and enhance overall success at smoking cessation.[5] In most reviews, 6-month quit rates with behavior therapies are 20% to 25%, and behavior therapy typically increases quit rates up to two-fold over standard medical advice. The primary

goals of behavioral therapies in treatment of tobacco dependence include providing necessary skills to smokers to aid them in quitting smoking and teaching skills to avoid smoking in high-risk situations.

Brief Interventions

Brief advice has been found to increase smoking cessation rates and has been strongly endorsed in the latest U.S. Department of Health and Human Services Guidelines on Tobacco Dependence Treatment. Therefore, it is recommended that physicians use the "5 As" with all patients (*Ask* patients if they smoke, *Advise* patients to quit, *Assess* patients' motivation level for quitting, *Assist* with quit attempts, and *Arrange* follow-up contacts). Providing self-help material is a form of brief intervention used to increase motivation to quit and impart smoking cessation skills. Several recent studies have documented that minimal behavioral interventions such as community support groups, telephone counseling, and computer-generated tailored self-help materials can augment smoking cessation rates in controlled settings.

Motivational Interventions

The goal of motivational interviewing (MI) interventions is to elicit change through addressing ambivalence, increasing intrinsic motivation for change, and creating an atmosphere of acceptance in which patients take responsibility for making changes happen. Brief MI interventions have been developed for smoking cessation, and there is some evidence for increased smoking cessation using MI techniques.

TABLE 32-1 BEHAVIORAL TREATMENTS FOR TOBACCO DEPENDENCE

BEHAVIORAL TREATMENTS	MECHANISM OF ACTION	
Brief interventions	Increase motivation to quit and impart cessation skills (e.g., community support, telephone counseling)	2
Cognitive-behavioral and relapse-prevention therapies	Behavioral strategies are developed to manage triggers; cognitive coping strategies target maladaptive thoughts to prevent relapse	1
Motivational interviewing	Therapist promotes patient's self-motivational statements, and in turn, patient gains greater awareness of the problems with smoking; increases intention for smoking cessation	2

Effectiveness rating: 1 = strong evidence to support efficacy; 2 = moderate evidence to support efficacy; 3 = little evidence to support efficacy

Cognitive-Behavioral Therapies

In cognitive behavioral therapy (CBT), patients learn to anticipate situations in which they are likely to smoke and then plan to cope with these situations using behavioral (e.g., substitution of behavior) and cognitive (e.g., challenging thoughts) techniques. Some degree of efficacy of CBT in smokers has been observed for both individual and group counseling formats.

Relapse-Prevention (Coping Skills) Therapies

A large number of smokers relapse within 6 months of quitting. Focusing on relapse prevention skills, including recognizing high-risk situations and coping with lapses, can be included in initial smoking cessation treatment or following a quit attempt.

Pharmacologic Treatments

There are three U.S. Food and Drug Administration (FDA)-approved classes of smoking cessation pharmacotherapies: nicotine replacement therapy (NRT), sustained-release bupropion, and varenicline[6] (Table 32-2).

Nicotine Replacement Therapies

The goal of NRT is to alleviate tobacco withdrawal, which allows smokers to focus on habit and conditioning factors when attempting cessation. NRTs rely on systemic venous absorption and so do not produce the rapid high levels of arterial nicotine achieved when cigarette smoke is inhaled. Thus, individuals are unlikely to become addicted to NRT. Safety concerns regarding smoking while using an NRT patch appear to be less serious than previously thought. The most recent evidence suggests that treatment with a nicotine patch while concomitantly smoking is not hazardous, and that use of NRT *before* the quit date may actually facilitate smoking cessation compared with when given at the time of quitting smoking. All commercially available forms of NRT are effective and increase quit rates approximately 1.5- to 2.5-fold compared with placebo. The transdermal patch, gum, and lozenge are available over the counter (OTC), whereas the nasal spray is available by prescription.

Nicotine Gum

Nicotine ingested orally is extensively metabolized on first pass through the liver. Nicotine polacrilex gum avoids this problem through buccal absorption. Nicotine gum was approved as an OTC medication in the United States in 1996 and contains 2 or 4 mg of nicotine that can be released from a resin by chewing. Nicotine gum should be administered by scheduled dosing (e.g., 1 piece of 2-mg gum/hour). The original recommended duration of treatment was 3 months, although many experts believe longer treatment is more effective. Nicotine absorption from the gum peaks 30 minutes after beginning to use the gum. Venous nicotine levels from 2- and 4-mg gum are about one third and two thirds, respectively, of the steady-state (e.g., between cigarettes) levels of nicotine achieved with cigarette smoking. Nicotine delivered by cigarettes is absorbed directly into the pulmonary arterial circulation. Thus, arterial

TABLE 32-2 PHARMACOLOGIC TREATMENTS FOR TOBACCO DEPENDENCE

NICOTINE REPLACEMENT THERAPIES*		
Gum (OTC)	Slow nicotine absorption gradually reduces nicotine craving and withdrawal	1
Transdermal nicotine patch (OTC)	Slow nicotine absorption gradually reduces nicotine craving and withdrawal	1
Lozenge (OTC)	Slow nicotine absorption gradually reduces nicotine craving and withdrawal	1
Vapor inhaler (prescription) and e-cigarettes (nonprescription)	Fast nicotine absorption leads to stimulation of nAChR, which rapidly reduces nicotine craving and withdrawal. Electronic cigarettes (e-cigarettes) are not approved by the FDA and are under study to compare with other nicotine replacement therapies.	1
Nasal spray (prescription)	Fast nicotine absorption leads to stimulation of nAChR, which reduces craving and withdrawal	1
NON-NICOTINE PHARMACOTHERAPIES		
Bupropion SR*	Blocks reuptake of DA and NA; high-affinity, noncompetitive nAChR antagonism reduces nicotine reinforcement, withdrawal, and craving	1
Varenicline*	Acts as a partial agonist of $\alpha_4\beta_2$ nAChRs	1
Nortriptyline	Blocks reuptake of NA and 5-HT; probably reduces withdrawal symptoms and comorbid depressive symptoms; side effects limit utility.	1-2
Clonidine	α_2-Adrenoreceptor agonist reduces nicotine withdrawal symptoms	2
Mecamylamine	Noncompetitive, high-affinity nAChR antagonist combined with TNP reduces nicotine reinforcement, craving, and withdrawal and may increase smoking cessation rates versus TNP alone.	2-3
Naltrexone	Minimal evidence that this μ-opioid peptide receptor antagonist improves smoking cessation outcomes alone, or in combination with TNP. It may reduce alcohol use, and obviate cessation-induced weight gain.	3
Cytisine	Nicotinic partial agonist appears to be safe and efficacious for smoking cessation.	2
Nicotine vaccine	Limited evidence of efficacy for smoking cessation in early human trials, and recent phase III trials have been negative.	3

*Approved by the U.S. Food and Drug Administration (FDA).
Effectiveness rating: 1 = strong evidence to support efficacy; 2 = moderate evidence to support efficacy; 3 = little evidence to support efficacy.
5-HT = serotonin; DA = dopamine; NA = norepinephrine; nAChR= nicotine acetylcholine receptor; OTC = over the counter; TNP = transdermal nicotine patch.

levels from smoking are 5 to 10 times higher than those from the 2- and 4-mg gums. Absorption of nicotine in the buccal mucosa is decreased by an acidic environment, and patients should not drink beverages (e.g., coffee, soda, juice) immediately before, during, or after nicotine gum use.

Several placebo-controlled trials established the safety and efficacy of nicotine gum for smoking cessation.[6] There appears to be some evidence to support using higher doses of nicotine gum (4 mg pieces) in more highly dependent cigarette smokers (≥25 cigarettes per day [cpd]), which supports the idea of matching nicotine gum dose to dependence level of the smoker. Side effects from nicotine gum are rare and include those of mechanical origin (e.g., difficulty chewing, sore jaw) or of local pharmacologic origin (e.g., burning in mouth, throat irritation). Tolerance develops to most side effects over the first week, and education about proper use of the gum (e.g., do not chew too vigorously) decreases side effects.

Nicotine Lozenges

Nicotine lozenges that deliver nicotine (2 and 4 mg preparations) by buccal absorption were approved for OTC use in the United States in 2002. Lozenges offer further flexibility for nicotine replacement options for smokers and are known to allow greater absorption of nicotine compared with nicotine gum. Mild throat and mouth irritation have been reported in preliminary trials. Nicotine lozenges have shown their superiority to placebo lozenges, with significant reduction in nicotine craving and withdrawal. Furthermore, high lozenge doses may be more efficacious in more highly dependent smokers, suggesting that, similar to nicotine gum, lozenge dose can be matched with dependence level. Interestingly, the combination of nicotine lozenge and nicotine patch may lead to the higher long-term quit rates compared with both NRT monotherapies and bupropion.

Transdermal Nicotine Patch

Transdermal nicotine patch (TNP) formulations take advantage of ready absorption of nicotine across the skin. Three of the formulations are for 24-hour use, and one is for 16-hour use. Starting doses are 21 to 22 mg/24-hour patch and 15 mg/16-hour patch. Patches are applied daily each morning. Nicotine administered by patches is slowly absorbed so that, on the first day, venous nicotine levels peak 6 to 10 hours after administration. Thereafter, nicotine levels remain fairly steady, with a decline from peak to trough of 25% to 40% with 24-hour patches. Nicotine levels obtained with the use of patches are typically half those obtained by smoking. After 4 to 6 weeks on high-dose patch (21 or 22 mg/24 hours, and 15 mg/16 hours), smokers are tapered to a middle dose (e.g., 14 mg/24 hours or 10 mg/16 hours) and then to the lowest dose after an additional 2 to 4 weeks (7 mg/24 hours or 5 mg/16 hours). Most studies suggest that abrupt cessation of the use of patches often causes no significant withdrawal; thus, tapering does not appear to be necessary. The recommended total duration of treatment is usually 6 to 12 weeks.

The overall efficacy of the TNP for smoking cessation has been well documented.[6] The effects of active TNP are independent of patch type, treatment duration, tapering procedures, and behavioral therapy format or intensity, although it should be noted that behavioral treatment enhances outcomes with TNP compared with TNP alone. Severe adverse events with nicotine patches have not been found, with the most common minor side effects being skin reactions (50%), insomnia and increased or vivid dreams (15% with 24-hour patches), and nausea (5-10%). Tolerance to these side effects usually develops within a week. Rotation of patch sites decreases skin irritation. Insomnia reported in the first week after cessation appears to be mostly a result of nicotine withdrawal rather than the nicotine patch itself. A 24-hour patch can be removed before bedtime to determine whether the insomnia is caused by the nicotine patch. Without treatment, insomnia usually abates after 4 to 7 days. There is minimal dependence liability associated with patch use: only 2% of patch users continue to use it for an extended period after a cessation trial.

Nicotine Nasal Spray

Nicotine nasal spray is a nicotine solution in a nasal spray bottle similar to the type used with saline sprays. This NRT was approved for treatment of nicotine dependence in the United States in 1996. Nasal spray delivers about 1 mg nicotine per administration, and the patient administers the spray (10 mg/mL) to each nostril every 4 to 6 hours. This formulation produces a more rapid rise in nicotine levels than does nicotine gum, and the rise in nicotine levels produced by nicotine spray falls between the levels produced by nicotine gum and cigarettes. Peak nicotine levels occur within 10 minutes, and venous nicotine levels are about two thirds those of between-cigarette levels. Smokers may use the nasal spray as needed up to 30 times/day for 12 weeks.

Randomized, double-blind, placebo-controlled trials of nasal spray versus placebo spray[6] have established the safety and efficacy of the nasal spray for smoking cessation. Both trials employed treatment for 3 to 6 months, and active nasal spray led to a doubling of quit rates during active use. Differences were reduced or absent with extended follow-up, suggesting the need for maintenance use of this agent. However, such long-term studies to date have not been published. Major side effects from nicotine nasal spray are nasal and throat irritation, rhinitis, sneezing, coughing, and watering eyes. Nicotine nasal spray may have modest dependence liability; prolonged use occurs in about 10% of smokers using the nasal spray, so follow-up of smokers using nasal spray is recommended.

Nicotine Inhaler

Nicotine inhalers are cartridges (plugs) of nicotine (containing about 1 mg of nicotine each) placed inside hollow cigarette-like plastic rods. The cartridges produce a nicotine vapor when warm air is passed through them. Absorption from a nicotine inhaler is primarily buccal rather than respiratory. More recent versions of inhalers produce a rise in venous nicotine levels more rapidly than with nicotine gum but less rapidly than with nicotine nasal spray, with nicotine blood levels of about one third that of between-cigarette levels. Smokers are instructed to puff continuously on the inhaler (0.013 mg/puff) during the day, and recommended dosing is 6 to 16 cartridges daily. The inhaler is to be used as needed for about 12 weeks. No serious medical side effects have been reported with nicotine inhalers. Fifty percent of subjects report throat irritation or coughing. Double-blind, randomized controlled trials have demonstrated the superiority of inhaler to placebo inhalers for smoking cessation. Results revealed a two- to three-fold increase in quit rates (17 to 26%) at trial end point compared with placebo inhalers, and smaller differences at follow-up periods of 1 year or longer. These data support the short-term efficacy of the inhaler in cigarette smokers, but longer-term trials with the inhaler are needed, and there is some modest concern about abuse liability based on long-term use of the product in more than 10% of smokers.

Since their introduction in 2004, electronic cigarettes (e-cigarettes) to deliver nicotine have been purchased by millions (and rapidly increasing numbers) of people. Their role in tobacco control has been controversial, and there is a dearth of strong data to support or refute their efficacy in mitigating tobacco withdrawal and assisting quit attempts by smokers. One recent randomized controlled trial found that 13 weeks of nicotine e-cigarette use resulted in increased smoking abstinence at 6 months compared with use of patches or placebo e-cigarettes, although these differences were not statistically significant. Additional research will be required to determine their benefits and harms at both individual and population levels.[7]

Sustained-Release Bupropion

The phenylaminoketone, atypical antidepressant agent bupropion, in the sustained-release (SR) formulation (Zyban), is a non-nicotine first-line pharmacologic treatment approved by the FDA for nicotine dependent smokers who want to quit smoking. The mechanism of action of this antidepressant agent in the treatment of nicotine dependence likely involves dopamine and norepinephrine reuptake blockade, as well as antagonism of high-affinity nAChRs. The exact mechanism by which bupropion exerts antismoking effects is unclear. The goals of bupropion therapy are smoking cessation, reduction of nicotine craving and withdrawal symptoms, and prevention of cessation-induced weight gain.

The target dose of bupropion in nicotine dependence is 300 mg daily (150 mg bid), and it is typically started 7 days before the target quit date (TQD) at 150 mg daily, then increased to 150 mg twice daily after 3 or 4 days. Unlike with the NRTs, there is no absolute requirement that smokers completely cease smoking by the TQD, although many smokers report a significant reduction in urges to smoke and craving that facilitates cessation at the time of the TQD when drug levels reach steady-state plasma levels. Some smokers gradually reduce their cigarette smoking over several weeks before quitting.

A pivotal multicenter study established the efficacy and safety of bupropion SR for treatment of nicotine dependence, which led to its FDA approval in the United States in 1998. In a 7-week double-blind, placebo-controlled multicenter trial, four doses of bupropion SR (0, 100, 150, and 300 mg/day in twice-daily dosing), in combination with weekly individual cessation counseling, were prescribed to 615 cigarette smokers using at least 15 cpd. At 1-year follow-up, cessation rates were 12.4%, 19.6%, 22.9%, and 23.1%, respectively. Bupropion SR treatment dose-dependently reduced weight gain associated with smoking cessation and significantly reduced nicotine withdrawal symptoms at the 150- and 300-mg/day doses.

Subsequently, the efficacy of the combination of bupropion SR and TNP was studied in a double-blind, placebo-controlled, randomized multicenter trial. A total of 893 cigarette smokers, using at least 15 cpd, were randomized to one of four experimental groups: (1) placebo bupropion + placebo patch; (2) placebo bupropion + TNP; (3) bupropion (300 mg/day) + placebo patch; or (4) bupropion + TNP. Cessation rates at the 1-year follow-up assessment were 15.6%, 16.4%, 30.3%, and 35.5%, respectively. The bupropion groups were significantly better than the placebo-alone and TNP-alone conditions, but the combination of bupropion and TNP was not significantly better than bupropion alone. Weight suppression after cessation was most robust in the combination therapy group. Finally, a randomized controlled trial has demonstrated the efficacy of sustained-release bupropion in relapse prevention after smoking cessation. In individuals who quit smoking with 7 weeks of bupropion (300 mg/day) treatment, bupropion SR versus placebo for 12 months delayed smoking relapse and resulted in weight gain.

Common side effects reported with bupropion administration in cigarette smokers are headache, nausea and vomiting, dry mouth, insomnia, and activation, most of which occur during the first week of treatment. The main contraindication for the use of bupropion is a past history of seizures of any etiology. The rates of de novo seizures are low with this agent (<0.5%) at doses of 300 mg daily or less, and seizures have been observed when daily dosing exceeds 450 mg/day.

Varenicline

Varenicline tartrate (Chantix in the United States, Champix in Europe and Canada), an $\alpha_4\beta_2$ nAChR partial agonist, was approved as a first-line smoking cessation agent by the FDA in 2006 and in Canada and Europe in 2007. Varenicline (2 mg/day) is at least as good if not better than bupropion SR (300 mg/day) for providing long-term abstinence from cigarette smoking. Continuous abstinence over the follow-up period (weeks 9 to 52) were lower, and participants taking varenicline continued to show a higher rate of abstinence than participants taking bupropion and placebo. Varenicline has been also found to be effective in preventing smoking relapse compared with placebo.

Varenicline reduces tobacco cravings and smoking satisfaction and is generally well tolerated. The most common adverse events reported in the initial studies were nausea and insomnia. However, since approval of the drug, concerns have arisen over treatment-emergent neuropsychiatric events, including agitation, suicidal and homicidal ideation, mania, and psychosis. Thus, close monitoring of smokers, especially those with a history of psychiatric illness, has been strongly advised when prescribing this agent. In fact, there is recent evidence that vareniciline appears to be safe and efficacious in smokers with comorbid psychiatric disorders[8] and specifically disorders such as schizophrenia and bipolar disorder.

Combination Pharmacotherapies

There is substantial evidence to suggest that combining various formulations of NRTs, combining NRTs with bupropion SR or varenicline, or combining bupropion with varenicline may lead to enhanced smoking cessation outcomes compared with monotherapies. Although, less is known about how best to switch medications in the case of initial nonresponse, a recent study that used an adaptive trial design demonstrated that initial response to transdermal nicotine (e.g., a 50% reduction in smoking in the first 2 weeks after patch application) predicted success in subsequent smoking cessation. Moreover, those who failed to respond initially to transdermal nicotine responded to augmentation to bupropion SR or a switch to varenciline. Further studies of combination pharmacotherapies and strategies for switching among approved medications are warranted.

Off-Label Medications

Other medications (see Table 32-2) have demonstrated some evidence of efficacy for tobacco treatment, but are otherwise not approved for use for this indication and should be considered second-line treatments.

PREVENTION

Tobacco dependence remains one of the leading preventable causes of morbidity and mortality in the Western world. Nonetheless, smoking cessation therapies are amongst the most cost-effective and proven therapies in medicine. Yet, most health care providers do not identify tobacco use in their patients. Recent recommendations suggest that all smokers should be approached about quitting smoking. Moreover, effective tobacco policies such as state taxes and prevention efforts targeted to reducing the initiation of tobacco use by youth and adults are critical elements in the overall strategy to reduce the burden of tobacco-related disease and related social and health care costs.

PROGNOSIS

The prognosis for tobacco smokers who quit is excellent in terms of years of life and quality of life gained, and earlier quitting appears to be associated with increases in lifespan and quality of life.[9] Furthermore, although medication and behavioral treatments have documented efficacy in treating tobacco dependence, it is important that these therapies be used in combination to achieve the best overall results and ensure adequate skill acquisition and treatment adherence. The promise of novel treatment and prevention interventions and the employment of personalized medicine matching the right medications to smokers with preferential responses using pharmacogenetic (e.g. polymorphisms in genes for catecholamine-*O*-methyltransferase and the nicotinic receptor subunits CHRNA3 and CHRNA4) and neuroimaging biomarkers (e.g., positron emission tomography and functional magnetic resonance imaging) are of considerable excitement for the tobacco treatment field[10] and may be realized within the next decade. Furthermore, given the high rates of tobacco use and dependence in psychiatric populations and the lower rates of quitting in this subset of smokers compared with the general population, specific adaptation of tobacco treatments to mentally ill smokers will be of paramount importance to improving prognosis and outcomes in these hard-to-treat groups of smokers.[11] Additional future challenges include developing safer and more effective smoking cessation therapies and making these therapies available to all smokers who wish to quit.

REVIEW QUESTIONS

1. Which of the following is the level of reduction in smoking that is associated with significant lowering of cardiovascular and respiratory disease risk?

A. 25%
B. 50%
C. 75%
D. 100%

Answer: D See Epidemiology section.

2. Which of the following signs and symptoms is NOT associated with nicotine withdrawal?

A. Irritability
B. Insomnia
C. Weight gain
D. Gastrointestinal discomfort

Answer: D See Diagnosis section.

3. Polymorphisms in the following genes have been associated with successful smoking cessation outcomes, EXCEPT which gene?

A. CHRNA4
B. Neuregulin
C. COMT
D. CHRNA3

Answer: B See Prognosis section.

4. Which of the following is NOT an evidence-based behavioral interventions for smoking cessation?

A. Cognitive behavioral therapy (CBT)
B. Motivational interviewing
C. Dialectical behavioral therapy (DBT)
D. Brief interventions

Answer: C See Table 32-1.

5. Which of the following medications may be effective as adjunctive treatment to behavioral therapies for smoking cessation?

A. Naltrexone
B. Nicotine vaccine
C. Mecamylamine
D. Nortriptyline

Answer: D See Table 32-2.

33 ALCOHOL USE DISORDERS

PATRICK G. O'CONNOR

DEFINITION

A variety of terms have been used to describe the spectrum of medical, psychological, behavioral, and social problems associated with excessive consumption of alcohol (*alcohol problems*). *Alcoholism* is perhaps the most widely used term to describe patients with alcohol problems. In an attempt to define *alcoholism* more precisely, an expert panel of the National Council on Alcoholism and Drug Dependence and the American Society of Addiction Medicine developed a definition of alcoholism that included "a primary chronic disease with genetic, psychosocial and environmental factors … often progressive and fatal … characterized by impaired control over drinking, preoccupation with the drug alcohol, use of alcohol despite future consequences, and distortions of thinking, most notably denial." Because the term *alcoholism* is so broad, it also can be imprecise in defining the entire spectrum of alcohol problems.

Abstainers are individuals who consume no alcohol. *Moderate drinking* is defined by the National Institute on Alcohol Abuse and Alcoholism as the average number of drinks consumed daily that places an adult at low risk for alcohol problems. There is some epidemiologic evidence to suggest that moderate drinking may have some health benefits by reducing the risk for cardiovascular disease (Chapter 52). The scope of alcohol consumption that imparts this benefit may be low, however (e.g., less than one drink per day).

At-risk drinking is a level of alcohol consumption that imparts health risks (Table 33-1). This category of drinking behavior has been identified on the basis of epidemiologic evidence that certain threshold levels of alcohol consumption are associated with increased risk for specific health problems.

TABLE 33-1 TERMS AND CRITERIA FOR PATTERNS OF ALCOHOL USE

AT-RISK DRINKING
Men: >14 drinks/week or >4 drinks/day Women: >7 drinks/week or >3 drinks/day
ALCOHOL USE DISORDER CRITERIA*
Tolerance Withdrawal More use than intended Craving Unsuccessful attempts to cut down Excessive time acquiring alcohol Activities given up because of use Use despite negative effects Failure to fulfill major role obligations Recurrent use in hazardous situations Continued use despite social or intrapersonal problems

*Mild = 2-3 criteria, moderate = 4-5 criteria, severe = 6 or more criteria.
(From American Psychiatric Association. *Diagnostic and Statistical Manual of Mental Disorders*. 5th ed. Arlington, VA: American Psychiatric Publishing; 2013.)

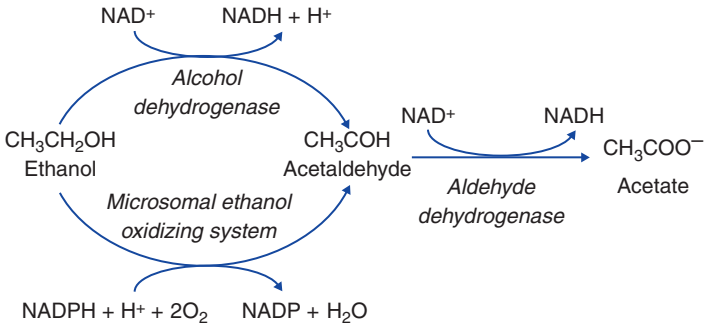

FIGURE 33-1. Ethanol metabolism. Alcohol dehydrogenase predominates at low to moderate ethanol doses. The microsomal ethanol-oxidizing system is induced at high ethanol levels of chronic exposure and by certain drugs. Aldehyde dehydrogenase inhibition (genetic or drug induced) leads to acetaldehyde accumulation, particularly in the latter group.

At-risk drinking is defined differently for men younger than 65 years than for women of all ages because of generally lower body weights and lower rates of metabolism of alcohol in women; the definition in men older than 65 years is the same as in women because of the age-related increased risk for alcohol problems, in part owing to changes in alcohol metabolism in older individuals. *Binge drinking* or *heavy drinking* is the episodic consumption of large amounts of alcohol, usually five or more drinks per occasion for men and four or more drinks per occasion for women. One standard drink contains 12 g of pure alcohol, an amount equivalent to that contained in 5 ounces of wine, 12 ounces of beer, or 1.5 ounces of 80-proof spirits.

The recently published *Diagnostic and Statistical Manual of Mental Disorders,* 5th edition (DSM-5) replaced the previous terminology of *alcohol abuse* and *alcohol dependence* with the term *alcohol use disorders* (see Table 33-1) in order to more clearly describe the spectrum of symptoms experienced by patients. Patients who meet 2 or 3 criteria are considered to have *mild,* 4 or 5 criteria *moderate,* and 6 to 11 criteria *severe* alcohol use disorder.[1]

EPIDEMIOLOGY

In national surveys, 52% of American adults reported that they use alcoholic beverages (liquor, wine, or beer), whereas 23% reported binge drinking, and 6.5% reported heavy drinking in the past 30 days.[2] Among individuals who use alcohol, many experience problems because of their drinking. It has been estimated that more than $100 billion is spent by American society each year to treat alcohol use disorders and to recover the costs of alcohol-related economic losses. Excessive alcohol consumption ranks as the third leading preventable cause of death in the United States after cigarette smoking and obesity. More than 100,000 deaths per year in the United States are attributed to alcohol use disorders.

Population-based epidemiologic studies have shown that alcohol use disorders are among the most prevalent medical, behavioral, or psychiatric disorders in the general population. An epidemiologic survey of the general population in the United States estimated a prevalence of alcohol abuse and dependence (using the older DSM-IV criteria) to be between 7.4 and 9.7%. The lifetime prevalence of abuse and dependence is estimated to be even higher. Despite higher thresholds and tolerance, men are at least twice as likely as women to meet criteria for alcohol abuse and dependence by standard diagnostic survey techniques. Although sociodemographic features, such as young age, low income, and low education level, have been associated with an increased risk for problem drinking, alcohol use disorders are prevalent throughout all sociodemographic groups, and all individuals should be screened carefully. The "skid row" stereotype of the alcohol-dependent patient is much more the exception than the rule.

The prevalence of alcohol use disorders is higher in most health care settings than it is in the general population because alcohol problems often result in treatment-seeking behaviors. The prevalence of problem drinking in general outpatient and inpatient medical settings has been estimated between 15 and 40%. These data strongly support the need for physicians to screen all patients for alcohol use disorders.

PATHOBIOLOGY

Beverage alcohol contains ethanol, which acts as a sedative-hypnotic drug. Alcohol is absorbed rapidly into the blood stream from the stomach and intestinal tract. Because women have lower levels of gastric alcohol dehydrogenase, the enzyme primarily responsible for metabolizing alcohol, they experience higher blood alcohol concentrations than do men who consume similar amounts of ethanol per kilogram of body weight. The absorption of alcohol can be affected by other factors, including the presence of food in the stomach and the rate of alcohol consumption. By means of metabolism in the liver, alcohol is converted to acetaldehyde and acetate (Fig. 33-1). Metabolism is proportional to an individual's body weight, but a variety of other factors can affect how alcohol is metabolized. A genetic variation in a significant proportion of the Asian population alters the structure of an aldehyde hydrogenase isoenzyme, resulting in the development of an alcohol flush reaction, which includes facial flushing, hot sensations, tachycardia, and hypotension.

In the brain, alcohol seems to affect a variety of receptors, including γ-aminobutyric acid (GABA), *N*-methyl-D-aspartate, and opioid receptors. Glycinuric and serotoninergic receptors also are thought to be involved in the interaction between alcohol and the brain. The phenomena of reinforcement and cellular adaptation are thought, at least in part, to influence alcohol-dependent behaviors. Alcohol is known to be reinforcing because withdrawal from ethanol and ingestion of ethanol itself are known to promote further alcohol consumption. After chronic exposure to alcohol, some brain neurons seem to adapt to this exposure by adjusting their response to normal stimuli. This adaptation is thought to be responsible for the phenomenon of tolerance, whereby increasing amounts of alcohol are needed over time to achieve desired effects. Although much has been learned about the variety of effects alcohol can have on various brain receptors, no single receptor site has been identified. A variety of neuropsychological disorders are seen in association with chronic ethanol use, including impaired short-term memory, cognitive dysfunction, and perceptual difficulties.

Although the brain is the primary target of alcohol's actions, a variety of other tissues have a major role in how alcohol affects the human body. Direct liver toxicity may be among the most important consequences of acute and chronic alcohol use (Chapter 152). A variety of histologic abnormalities ranging from inflammation to scarring and cirrhosis have been described. The pathophysiologic mechanism of these effects is thought to include the direct release of toxins and the formation of free radicals, which can interact negatively with liver proteins, lipids, and DNA. Alcohol also has substantial negative effects on the heart and cardiovascular system. Direct toxicity to myocardial cells frequently results in heart failure (Chapter 58), and chronic heavy alcohol consumption is considered to be a major contributor to hypertension (Chapter 67). Other organ systems that experience significant direct toxicity from alcohol include the gastrointestinal tract (esophagus, stomach), immune system (bone marrow, immune cell function), and endocrine system (pancreas, gonads).

CLINICAL MANIFESTATIONS

Alcohol has a variety of specific acute and chronic effects. The acute effects seen most commonly are alcohol intoxication and alcohol withdrawal. Chronic clinical effects of alcohol include almost every organ system.

Acute Effects

Alcohol Intoxication

After entering the blood stream, alcohol rapidly passes through the blood-brain barrier. The clinical manifestations of alcohol intoxication are related directly to the blood level of alcohol. Because of tolerance, individuals chronically exposed to alcohol generally experience less severe effects at a given blood alcohol level than do individuals who are not chronically exposed to alcohol.

The symptoms of mild alcohol intoxication in nontolerant individuals typically occur at blood alcohol levels of 20 to 100 mg/dL and include euphoria, mild muscle incoordination, and mild cognitive impairment. At higher blood alcohol levels (100 to 200 mg/dL), more substantial neurologic dysfunction occurs, including more severe mental impairment, ataxia, and prolonged reaction time. Individuals with blood alcohol levels in these ranges can be obviously intoxicated, with slurred speech and lack of coordination. These effects progress as the blood alcohol level rises to higher levels, to the point at which stupor, coma, and death can occur at levels equal to or greater than 300 to 400 mg/dL, especially in individuals who are not tolerant to the effects of alcohol. The usual cause of death in individuals with very high blood levels of alcohol is respiratory depression and hypotension.

Alcohol Withdrawal Syndrome

Alcohol withdrawal can occur when individuals decrease their alcohol use or stop using alcohol altogether. The severity of symptoms can vary greatly. Many individuals experience alcohol withdrawal without seeking medical attention, whereas others require hospitalization for severe illness. Because ethanol is a central nervous system depressant, the body's natural response to withdrawal of the substance is a hyperexcitable neurologic state. This state is thought to be the result of adaptive neurologic mechanisms being unrestrained by alcohol, with an ensuing release of a variety of neurohumoral substances, including norepinephrine. In addition, chronic exposure to alcohol results in a decrease in the number of GABA receptors and impairs their function.

The clinical manifestations of alcohol withdrawal include hyperactivity resulting in tachycardia and diaphoresis. Patients also experience tremulousness, anxiety, and insomnia. More severe alcohol withdrawal can result in nausea and vomiting, which can exacerbate metabolic disturbances. Perceptual abnormalities, including visual and auditory hallucinations and psychomotor agitation, are common manifestations of more moderate to severe alcohol withdrawal. Grand mal seizures commonly occur during alcohol withdrawal, although they do not generally require treatment beyond the acute withdrawal phase.

The time course of the alcohol withdrawal syndrome can vary within an individual and by symptom complex, and the overall duration of symptoms can be a few to several days (Fig. 33-2). Tremor is typically among the earliest symptoms and can occur within 8 hours of the last drink. Symptoms of tremulousness and motor hyperactivity typically peak within 24 to 48 hours. Although mild tremor typically involves the hands, more severe tremors can involve the entire body and greatly impair a variety of basic motor functions. Perceptual abnormalities typically begin within 24 to 36 hours after the last drink and resolve within a few days. When withdrawal seizures occur, they are typically generalized tonic-clonic seizures and most often occur within 12 to 24 hours after reduction of alcohol intake. Seizures can occur, however, at later time periods as well.

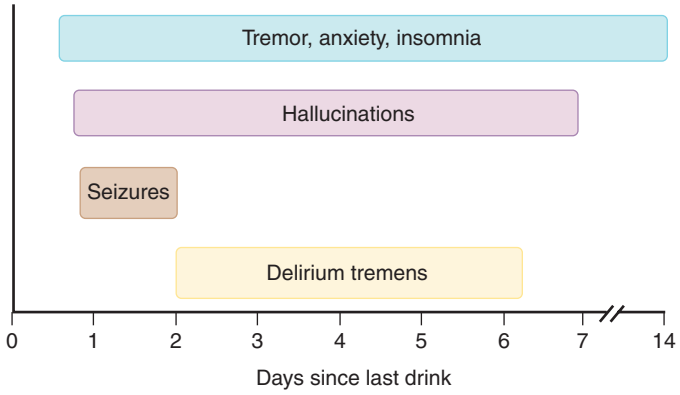

FIGURE 33-2. Time course of alcohol withdrawal.

The most severe manifestation of the alcohol withdrawal syndrome is delirium tremens. This symptom complex includes disorientation, confusion, hallucination, diaphoresis, fever, and tachycardia. Delirium tremens typically begins after 2 to 4 days of abstinence, and the most severe form can result in death.[3]

Chronic Effects

Acute manifestations, including intoxication and withdrawal, are generally stereotypical in their appearance and time course, but chronic manifestations tend to be more varied. Many patients with alcohol dependence may be without evidence of any chronic medical manifestations for many years. As time goes on, however, the likelihood that one or more of these manifestations will occur increases considerably. All major organ systems can be affected, but the primary organ systems involved are the nervous system, cardiovascular system, liver, gastrointestinal system, pancreas, hematopoietic system, and endocrine system (Table 33-2). Patients who drink are at risk for a variety of malignant neoplasms, such as head and neck, esophageal, colorectal, breast, and liver cancers (see individual chapters on those cancers). Excessive alcohol use often causes significant psychiatric and social morbidity that can be more common and more severe than the direct medical effects, especially earlier in the course of problem drinking.

Nervous System

In addition to the acute neurologic manifestations of intoxication and withdrawal, alcohol has major chronic neurologic effects. About 10 million Americans have identifiable nervous system impairment from chronic alcohol use. Individual predisposition to these disorders is highly variable and is related to genetics, environment, sociodemographic features, and gender; the relative contribution of these factors is unclear.

In the central nervous system, the major effect is cognitive impairment. Patients may present with mild to moderate short-term or long-term memory problems or may have severe dementia resembling Alzheimer disease (Chapter 402). The degree to which the direct toxic effect of alcohol is responsible for these problems or the impact of alcohol-related nutritional

TABLE 33-2 ALCOHOL-RELATED COMPLICATIONS

SYSTEM/REALM OF PROBLEM	COMPLICATIONS
Nervous system	Intoxication Withdrawal Cognitive impairment Cerebellar degeneration Peripheral neuropathy
Cardiovascular system	Cardiac arrhythmias Chronic cardiomyopathy Hypertension
Liver	Fatty liver Alcoholic hepatitis Cirrhosis
Gastrointestinal tract, esophagus	Chronic inflammation Malignant neoplasms Mallory-Weiss tears Esophageal varices
Stomach	Gastritis Peptic ulcer disease
Pancreas	Acute pancreatitis Chronic pancreatitis
Other medical problems	Cancers: mouth, oropharynx, esophagus, colorectal, breast, hepatocellular carcinoma Pneumonia Tuberculosis
Psychiatric	Depression Anxiety Suicide
Behavioral and psychosocial	Injuries Violence Crime Child or partner abuse Tobacco, other drug abuse Unemployment Legal problems

deficiencies is uncertain (Chapter 416). The deficiency of vitamins such as thiamine may plays a major role in promoting alcoholic dementia and severe cognitive dysfunction, as is seen in Wernicke encephalopathy and Korsakoff syndrome (Chapter 416). Alcohol also causes a polyneuropathy that can present with paresthesias, numbness, weakness, and chronic pain (Chapters 416 and 420). As with the central nervous system, peripheral nervous system effects are thought to be caused by a combination of the direct toxicity of alcohol and nutritional deficiencies. A small proportion (<1%) of patients with alcohol dependence may develop midline cerebellar degeneration, which presents as an unsteady gait.

Cardiovascular System

The most common cardiovascular complications of chronic alcohol consumption are cardiomyopathy, hypertension, and supraventricular arrhythmias. Alcoholic cardiomyopathy can present clinically in a manner similar to other causes of heart failure (Chapter 58). It is the most common cause of nonischemic cardiomyopathy in Western countries, accounting for about 45% of cases. Like these other causes, alcoholic cardiomyopathy also responds to conventional treatments of heart failure (Chapter 59). Abstinence from alcohol can result in significant improvement in cardiomyopathy in some patients. Increasing levels of alcohol consumption also are associated with increasing levels of systolic and diastolic hypertension (Chapter 67).

The most common arrhythmias associated with chronic alcohol use include atrial fibrillation and supraventricular tachycardia; these are seen commonly in the setting of acute intoxication and withdrawal (Chapter 64). The prevalence of alcohol-induced arrhythmias is unclear. Alcoholic cardiomyopathy also is associated with arrhythmias, in particular, ventricular arrhythmias (Chapter 65). Interestingly, the association between high levels of alcohol intake and increased cardiovascular mortality may be lessened in the presence of high physical activity.[4]

Liver

Alcohol abuse is the major cause of morbidity and mortality from liver disease in the United States. It has been estimated that there are more than 2 million people with known alcoholic liver disease in the United States. Factors that predispose to early liver disease include the quantity and duration of alcohol exposure, female gender, and malnutrition. The range of clinical manifestations includes acute fatty liver, alcoholic hepatitis, and cirrhosis (Chapter 153). Fatty liver associated with alcohol ingestion can be asymptomatic or associated with nonspecific abdominal discomfort; it generally improves with abstinence from alcohol. Alcoholic hepatitis can present as an asymptomatic condition identified through abnormalities in liver enzymes or as an acute episode with abdominal pain, nausea, vomiting, and fever. Patients with alcoholic hepatitis have particularly high levels of aspartate aminotransferase in the blood and elevated levels of γ-glutamyltransferase. Alcoholic hepatitis typically improves with abstinence from alcohol along with supportive care.

Alcohol-related cirrhosis is a major cause of death in the United States (Chapter 154). Although patients are often asymptomatic, patients with more advanced cirrhosis may present with a variety of symptoms and signs, including jaundice, ascites, and coagulopathy. Cirrhosis also is associated with gastrointestinal bleeding from esophageal varices (Chapter 138). Although there is some controversy about the use of liver transplantation to treat patients with alcoholic cirrhosis, many believe that patients in established recovery are good candidates for liver transplantation (Chapter 154). One randomized trial demonstrated that motivational enhancement therapy limited the quantity and frequency of pretransplantation alcohol consumption in patients with alcohol dependence.

Gastrointestinal Disease

Chronic alcohol use is associated with a variety of esophageal problems, including esophageal varices, Mallory-Weiss tears, and squamous cell carcinoma of the esophagus. The risk for squamous cell carcinoma is increased further in patients who smoke tobacco and drink alcohol (Chapter 192). Patients with these problems can present with difficulty swallowing, chest pain, gastrointestinal blood loss, and weight loss. Acute alcoholic gastritis typically presents with abdominal discomfort, nausea, and vomiting (Chapter 135).

Pancreas

The risk for pancreatitis in individuals with alcohol dependence is approximately four times that in the general population. Quantity and duration of alcohol exposure and a history of pancreatitis are predictive of future episodes. Acute alcoholic pancreatitis, which may present with severe abdominal pain, nausea, vomiting, fever, and hypotension, can be life-threatening (Chapter 144). Individuals who have recurrent acute pancreatitis may develop chronic pancreatitis, which typically presents with chronic abdominal pain, malabsorption, weight loss, and malnutrition.

Hematopoietic System

The anemia that commonly is seen in patients with chronic alcohol problems can be multifactorial (e.g., blood loss, nutrient deficiency, secondary to liver disease and hypersplenism). Studies of selected inpatients with alcohol dependence showed the prevalence of anemia to range from about 10 to 60%. Gastrointestinal blood loss due to Mallory-Weiss tears (Chapter 135), alcoholic gastritis (Chapter 132), or esophageal varices (Chapters 135 and 153) may be a key factor, and many patients develop subsequent iron deficiency. Dietary folate deficiency can be associated with megaloblastic anemias (Chapter 164). Alcohol also has a direct toxic effect on the bone marrow, which can lead to sideroblastic anemia that resolves after abstinence. Alcohol can suppress megakaryocyte production and cause thrombocytopenia, which may manifest as petechiae or bleeding (Chapter 172); the thrombocytopenia is particularly sensitive to abstinence, with platelet counts usually rebounding or returning to normal within 5 to 7 days after cessation of alcohol intake. Alcohol also appears to interfere directly with platelet function. Alcohol-related immune dysfunction, as evidenced by decreased production and function of white blood cells and derangement in humoral and cell-mediated immunity, partly explains why alcohol-dependent individuals are at higher risk for infectious diseases, such as pneumonia and tuberculosis.

Malignant Neoplasms

Alcohol intake has been associated with numerous cancers, including cancer of the upper digestive, respiratory, and liver malignant neoplasms. The amount of alcohol exposure that increases cancer risk may vary widely and may not correlate with what might be considered to be "safe" levels of alcohol consumption.[5] Concerning specific cancers, alcohol use is associated with squamous cell carcinomas of the esophagus (Chapter 192) and of the head and neck (Chapter 190). The co-occurrence of alcohol and tobacco abuse seems to be synergistic. Either heavy alcohol use or smoking individually increases the rate of oropharyngeal cancer by about six or seven times that of the general population, whereas the rate for people with both risk factors is about 40 times that of the general population. Patients with alcohol-induced liver disease who also have a history of hepatitis B or C are at particularly increased risk for hepatocellular carcinoma (Chapter 196).

Chronic alcohol use also has been associated with malignant neoplasms of the breast (Chapter 198), prostate (Chapter 201), pancreas (Chapter 194), cervix (Chapter 199), lung (Chapter 191), and colon (Chapter 193). Women who have more than one or two alcoholic drinks per day may increase their breast cancer risk 1.5-fold or more. Hormonal mechanisms and direct carcinogenic effects of alcohol have been postulated as causes of this association. The association of cervical cancer with alcohol dependence may be due to alcohol-associated high-risk sexual behaviors that are thought to increase the risk for cervical cancer.

Other Medical Issues

Gout has been associated with alcohol abuse, and flares can occur at lower serum urate levels than in nonalcoholic patients (Chapter 273). Alcoholic ketoacidosis (Chapter 118), which usually follows an alcoholic binge, presents as nausea, vomiting, abdominal pain, and volume depletion. Typically, ketoacidosis is seen with low or normal glucose readings. Mild or nonspecific abnormalities in thyroid function, especially in patients with underlying liver disease, may reflect abnormalities in the clearance of thyroid-stimulating hormone or the impact of elevated circulating estrogens. Infertility and menstrual irregularities have been associated with chronic alcohol consumption, presumably due to alcohol-induced hypothalamic-pituitary dysfunction, gonadal toxicity, and impaired hepatic metabolism of circulating hormones. Hypogonadism is highly prevalent in male alcoholics with cirrhosis. Alcohol dependence also is associated with higher rates of dental and periodontal disease (Chapter 425) and with a variety of dermatologic problems, including spider angiomas and, in patients with poor hygiene, skin infestations. Both at-risk drinking and alcohol dependence have been shown to be associated with an increased risk for hospital-acquired infections, sepsis, and mortality, especially in intensive care patients.

Psychiatric Issues

Psychiatric symptoms and illnesses are exceedingly common among individuals with alcohol problems. The prevalence of anxiety disorders is about 40%, and the prevalence of affective disorders is about 30%. Antisocial personality disorder is also more common in individuals with alcohol problems than in the general population. These psychiatric problems are more prevalent during periods of heavy drinking and withdrawal. All patients with alcohol use disorders require careful screening for psychiatric illnesses. Although alcohol dependence may be associated with worse outcomes in patients with common psychiatric problems such as depression and anxiety,[6] effective treatment of underlying psychiatric disorders may result in improved drinking behaviors.

Other Behavioral and Psychosocial Issues

Alcohol commonly is the underlying cause of domestic abuse, injuries, trauma, motor vehicle crashes, and burns. For example, of all substances of abuse, alcohol and cannabis appear to have the strongest association with intimate partner violence.[7] Patients presenting with injuries should be questioned carefully about their alcohol use. Tobacco use (Chapter 32) and other drug abuse (Chapter 34) are more prevalent in people with alcohol problems than in the general population.

DIAGNOSIS

Data from the history, physical examination, and laboratory generally are needed to provide a complete picture of the extent of alcohol problems in affected patients (Table 33-3).

Discussing the Diagnosis with Patients

In discussing alcohol problems, it is crucial that physicians be sensitive to the stigma and shame that may be felt by patients with alcohol problems and by their families. Alcohol-related diagnoses or problems should be discussed in a nonjudgmental manner, which forges a partnership and indicates commitment to helping with whatever problems the patients might have. Setting the stage for the discussion should include educating patients about the various levels of alcohol problems (e.g., at-risk drinking, alcohol use disorder) so that patients have an understanding of the spectrum of alcohol problems. Many patients may have a skewed view of what qualifies as problem drinking and may believe that only individuals with severe alcohol problems are truly problem drinkers. The history, physical examination, and laboratory studies should be provided as "proof" that a problem may or does exist.

TABLE 33-3 DIAGNOSIS OF ALCOHOL PROBLEMS

HISTORY
Step 1: Ask all patients about current and past use. Do you drink alcohol (ever or currently)? Do you have a family history of alcohol problems? Step 2: Obtain detailed history regarding quantity and frequency of alcohol use. What types of alcohol do you consume? How often do you drink? How much do you usually drink? Do you ever drink more, and if so, how much? Step 3: Standardized questionnaire CAGE questions: • Have you ever felt that you should ***c***ut down on your drinking? • Have people ***a***nnoyed you by criticizing your drinking? • Have you ever felt bad or ***g***uilty about drinking? • Have you ever taken a drink first thing in the morning (***e***ye opener) to steady your nerves or get rid of a hangover? Step 4: Assess specific areas in suspected or known problem drinkers. Criteria for alcohol abuse and dependence Evidence of medical and psychiatric problems Evidence of behavioral or social problems Use of other substances • Tobacco • Mood-altering prescription drugs • Illicit drugs (e.g., heroin, cocaine) • Prior alcohol or substance abuse treatment
PHYSICAL EXAMINATION
Thorough and complete examination important in all patients Focus attention to system with identified problems In all patients, carefully examine: Central and peripheral nervous systems Cardiovascular system Liver Gastrointestinal tract
LABORATORY STUDIES (IN SELECTED PATIENTS)
Liver enzymes Coagulation studies Complete blood count Carbohydrate-deficient transferrin

History

A four-step approach to the alcohol history includes comprehensive questions about alcohol use and a thorough evaluation for alcohol-related problems.

Step 1: Ask All Patients about Current and Past Alcohol Use

A single question—Do you currently or have you ever used alcohol?—can identify quickly patients who are not lifetime abstainers and require further screening. Patients who answer yes to this question should proceed through the subsequent three steps. Patients who answer no can be classified as lifetime abstainers from alcohol and require no further questioning unless their answer changes over time. It is crucial to ask about current and past alcohol use because many patients who meet lifetime criteria for alcohol use disorder but who are currently in recovery answer no to the question about current use; unless it is specifically asked about, important past use information may be missed.

Step 2: Obtain Detailed History Regarding Quantity and Frequency of Alcohol Use

A question to be asked routinely is, What type or types of alcoholic drinks (beer, wine, spirits) do you consume? Many patients do not consider the use of beer or wine "drinking." Quantity should be determined for typical use—How much do you usually drink on a typical drinking day?—and for range of use—Do you ever drink more than your usual amount, and if so, how much? This second question can be particularly important for identifying binge drinking. Quantity questions offer easy identification of at-risk drinking. Asking about the frequency of alcohol consumption—How often do you drink?—helps distinguish daily from nondaily alcohol users. Binge drinkers who drink only on weekends tend to have significant alcohol problems yet not be daily drinkers. A major goal of step 2 is to acquire a complete characterization of current alcohol use behaviors and the pattern of quantity and frequency of alcohol use during the patient's lifetime.

Step 3: Use Standardized Screening Instruments

Many standardized questionnaires have been developed to detect alcohol abuse and dependence. The two questionnaires that have been evaluated most extensively in medical settings are the CAGE (Cut down, Annoyed, Guilty, and Eye opener) questionnaire (see Table 33-3) and the Alcohol Use Disorder Identification Test (AUDIT). The CAGE questionnaire includes four questions and is scored by giving 1 point for each positive response. Given that the word *ever* is used in the CAGE questions, by definition this instrument is designed to detect lifetime alcohol problems and does not distinguish between lifetime problems and current problems. To screen for DSM-IV criteria alcohol abuse and dependence, the CAGE has a sensitivity of 43 to 94% and a specificity of 70 to 97% when a cutoff score of 2 is used to indicate a "positive" result. How this and other instruments relate to the new DSM-5 criteria for alcohol use disorder is the subject of ongoing inquiry.

The AUDIT's 10 questions cover the quantity and frequency of alcohol use, drinking behaviors, adverse psychological symptoms, and alcohol-related problems. The AUDIT was developed by the World Health Organization to identify hazardous (e.g., at-risk) drinking and harmful (e.g., alcohol use that results in physical or psychological harm) drinking. In contrast to the CAGE questionnaire, the AUDIT focuses on recent (current to past year) drinking behaviors. Each question is scored 0 to 4 (range for total score is 0 to 40), and a total score of 8 is considered to be a positive result.

Step 4: Assess Specific Areas in Suspected or Known Problem Drinkers

Questions asked in step 4 are based on the results of the questions asked in steps 2 and 3 to obtain more detailed information in patients with potential alcohol problems. Even patients who do not screen positive on the CAGE questionnaire may warrant detailed questioning about alcohol abuse and

dependence (see Table 33-1), especially if they are drinking at or above at-risk levels or there is other evidence of possible alcohol problems. A detailed review for evidence of alcohol-related medical and psychiatric problems should occur, and the need for further medical and psychiatric evaluation should be determined. The physician should look for evidence of behavioral and social problems commonly associated with alcohol use and screen for family and occupational dysfunction and other problems, such as domestic violence. Patients should be asked about their use of tobacco, mood-altering prescription medications, and illicit drugs such as heroine and cocaine.

Finally, many patients with alcohol problems have prior treatment episodes that should be detailed. The inquiry should include questions not only about formal alcohol treatment (including number of episodes, duration of treatment, and inpatient versus outpatient treatment) but also about more informal treatments, such as attendance at self-help groups like Alcoholics Anonymous (AA). For patients who require a referral for treatment, knowledge of prior treatment experience is a crucial determinant of future referral recommendations.

The National Institute on Alcohol Abuse and Alcoholism has published *Helping Patients Who Drink Too Much: A Clinician's Guide,* which provides a similar approach to screening and evaluating patients for alcohol-related problems and includes an appendix of useful supporting materials.

Physical Examination

Patients with potential alcohol use disorders require a detailed physical examination to complement the history. In addition, attention should be focused on detecting common alcohol-related problems, including the nervous system, cardiovascular system, liver, and gastrointestinal system (see Table 33-2).

Laboratory Findings

A variety of laboratory tests have been proposed to aid screening for alcoholic abuse and dependence. Aminotransferase levels, red blood cell, mean corpuscular volume, and carbohydrate-deficient transferrin, alone or in combination, are not as effective as screening questionnaires, such as the CAGE and the AUDIT.

Laboratory tests do have a role in diagnosis and assessment of patients with potential alcohol problems. Routine laboratory testing, including liver enzymes (Chapter 147), bilirubin, complete blood count, and prothrombin time should be obtained in all patients with alcohol problems on a regular basis so that an appropriate and complete picture of the effects of alcohol on the individual can be obtained.

PREVENTION AND TREATMENT

Rx

The relationship of change in alcohol use with prevention of subsequent problems has been well established. Treatment of alcohol use disorders should be based on the severity of potential or actual alcohol problems and tailored to meet the needs of individual patients. Separate advice and management approaches are suggested for nondependent at-risk or problem drinkers compared with individuals who are alcohol dependent (DSM-IV criteria) (Table 33-4). As with the screening instruments described previously, the manner in which the new DSM-5 criteria relate to specific treatment recommendations will become clearer in the near future.

Treatment of At-Risk Drinkers

Evidence confirms that generalist physicians, in a cost-effective manner, can help patients reduce their alcohol intake and prevent subsequent alcohol-related problems by using brief (5 to 20 minutes), focused counseling techniques (brief interventions) that are well suited for primary care and other medical settings.[8] More recent research has examined the use of brief interventions in more specialized settings, supporting their use in general medical inpatient settings and emergency departments.[■] Newer approaches to decreasing alcohol use in heavy drinkers include providing personalized advice by computer[■] and using text messaging and social media.

The brief counseling strategy includes four main components: motivational techniques, feedback about the problems with alcohol use, discussion of the adverse effects of alcohol, and setting recommended drinking limits. Motivational techniques are designed to motivate patients to change their alcohol use behavior by identifying potential or actual problems with which their alcohol use is associated. Feedback about these problems can make it clear to the patient that the problems exist. For at-risk and problem drinkers who do not meet criteria for alcohol dependence, setting recommended drinking limits below at-risk levels (e.g., less than one drink per day for women and less than two drinks per day for men) is a realistic and suitable goal. Epidemiologic evidence suggests that drinking below these levels is less likely to be associated with problems. Several randomized clinical trials confirm that patients who receive brief interventions significantly decrease their alcohol intake, often to "safe" levels, and can decrease health care use as well.

TABLE 33-4 ADVICE FOR PATIENTS WITH ALCOHOL PROBLEMS

State your medical concern:
Be specific about your patient's drinking patterns and related health risks.
Ask: How do you feel about your drinking?

Agree on a plan of action:
Ask: Are you ready to try to cut down or abstain?
Talk with patients who are ready to make a change in their drinking about a specific plan of action.

For patients who are not alcohol dependent:
Advise the patient to cut down if drinking is at or above at-risk drinking amounts (see Table 33-1) and there is no evidence of alcohol dependence.
Ask the patient to set a specific drinking goal: Are you ready to set a drinking goal? Some patients choose to abstain for a period of time or for good; others prefer to limit the amount they drink. What do you think will work best for you?
Provide patient education materials and tell the patient: It helps to think about your reasons for wanting to cut down and examine what situations trigger unhealthy drinking patterns. These materials will give you some useful tips on how to maintain your drinking goal.

For patients with evidence of alcohol dependence:
Advise to abstain if:
- Evidence of alcohol dependence
- History of repeated failed attempts to cut down
- Pregnant or trying to conceive
- Contraindicated medical condition or medication

Refer for additional diagnostic evaluation or treatment.
Procedures for patient in making referral decisions:
Involve your patient in making referral decisions.
Discuss available alcohol treatment services.
Schedule a referral appointment while the patient is in the office.

Treatment of Alcohol Use Disorders

Patients who meet criteria for an alcohol use disorder, in particular those who are dependent, usually require more intensive services than do patients who meet criteria for at-risk drinking. Most patients can be managed in outpatient treatment settings, whereas patients with a more severe alcohol use disorder or comorbid problems initially will likely require inpatient management, specific counseling programs, and pharmacologic therapy. Before entering a formal program to maintain remission, many patients first require medical management of alcohol withdrawal. Professional organizations have published practice guidelines that provide useful recommendations for how to select among treatment options for patients with alcohol dependence.

Management of Alcohol Withdrawal

Many patients may not present for medical management of alcohol withdrawal and deal with it on their own. However, a substantial subset do present for alcohol withdrawal treatment. Patients with mild to moderate withdrawal generally can be managed safely as outpatients with close follow-up. Patients with moderate to severe withdrawal, as manifested by hypertension, tremor, and any mental status changes, especially patients with significant comorbid medical or psychiatric illnesses, generally are treated best as inpatients. Patients who have a history of severe withdrawal in the past (e.g., delirium tremens) or who have a history of alcohol withdrawal seizures also generally should be managed as inpatients. The three major goals of medical management of alcohol withdrawal are to minimize the severity of withdrawal-related symptoms; to prevent specific withdrawal-related complications, such as seizures and delirium tremens; and to provide referral to relapse prevention treatment.

A wide variety of medications have been evaluated for their effectiveness in managing the alcohol withdrawal syndrome (Table 33-5). Longer-acting benzodiazepines are preferred because they provide a smoother withdrawal. Shorter-acting benzodiazepines, such as oxazepam, may be indicated in individuals with severe liver disease. The most common approach is to administer a standing dose of a benzodiazepine, with additional medication being given "as needed" on the basis of withdrawal symptoms. The specific benzodiazepine and dose often depend on the experience of the prescribing physician and the characteristics of the patient, including the severity of withdrawal (higher doses are used if withdrawal is more severe), the presence of liver disease (patients with severe liver disease should receive lower doses or shorter-acting medications), and the response to prior doses of medication (higher doses are given if symptom control is inadequate; lower doses are

TABLE 33-5 MEDICATIONS FOR THE TREATMENT OF ALCOHOL DEPENDENCE*

MEDICATION	DOSE AND ROUTE	FREQUENCY	EFFECTS	MAJOR COMMON ADVERSE EFFECTS
ALCOHOL WITHDRAWAL				
Benzodiazepines‡				
Chlordiazepoxide*	25-100 mg, PO/IV/IM‡	Every 4-6 hr	Decreased severity of withdrawal; stabilization of vital signs; prevention of seizures and delirium tremens	Confusion, oversedation, respiratory depression
Diazepam†	5-10 mg, PO/IV/IM‡	Every 6-8 hr		
Oxazepam†	15-30 mg, PO‡	Every 6-8 hr		
Lorazepam†	1-4 mg, PO/IV/IM‡	Every 4-8 hr		
β-Blockers				
Atenolol	25-50 mg, PO	Once a day	Improvement in vital signs	Bradycardia, hypotension
Propranolol	10-40 mg, PO	Every 6-8 hr	Reduction in craving	
α-Agonists				
Clonidine	0.1-0.2 mg, PO	Every 6 hr	Decreased withdrawal symptoms	Hypotension, fatigue
Antiepileptics				
Carbamazepine	200 mg, PO	Every 6-8 hr	Decreased severity of withdrawal; prevention of seizures	Dizziness, fatigue, red blood cell abnormalities
PREVENTION OF RELAPSE				
Disulfiram†	125-500 mg, PO	Daily	Decreased alcohol use among those who relapse	Disulfiram-alcohol reaction, rash, drowsiness, peripheral neuropathy
Naltrexone†	50 mg, PO 380 mg, IM	Daily Every 4 wk	Increased abstinence, decreased drinking days	Nausea, abdominal pain, myalgias-arthralgias
Acamprosate†	666 mg, PO	Three times a day	Increased abstinence	Diarrhea

*Most commonly used medications listed.
†Currently approved by U.S. Food and Drug Administration for the indication noted.
‡Dose and routes given for standard fixed-dose regimens, which include dose tapers over time.

given if adverse effects, such as oversedation, have occurred). In general, the amount of medication per dosing period is decreased gradually as the withdrawal syndrome abates. An individualized "symptom-triggered" dosing approach, in which benzodiazepines are administered on a dose-by-dose basis as guided by withdrawal symptoms, is safe and effective in certain patients and can reduce the total doses of benzodiazepines needed to treat withdrawal. β-Blockers (atenolol and propranolol), α-agonists (clonidine), and antiepileptics (carbamazepine) improve signs and symptoms of alcohol withdrawal but are viewed best as adjunctive medications to be used in addition to benzodiazepines.

Prevention of Relapse

Counseling Strategies Used by Alcohol Treatment Programs

Three commonly used psychotherapeutic techniques are motivational enhancement therapy, 12-step facilitation, and cognitive-behavioral coping skills. Two of these techniques are designed to give patients specific tools to help them avoid relapse to alcohol use. In motivational enhancement therapy, patients identify reasons for staying away from alcohol. The 12-step facilitation therapy uses the principles of AA to help patients focus their attention on abstinence. In cognitive-behavioral coping skills therapy, the patient identifies triggers to alcohol use and develops strategies to help deal with the triggers when they are present.

Project MATCH (Matching Alcohol Treatments to Client Heterogenicity) showed equivalence among three counseling approaches (cognitive-behavioral coping skills therapy, motivational enhancement therapy, or 12-step facilitation therapy) to treat alcohol dependence. At 1-year follow-up, most enrolled patients either remained abstinent or significantly decreased their alcohol use.

Self-Help Groups

Self-help groups such as AA and Rational Recovery are an important source of support and treatment for many patients with alcohol dependence. AA has the advantage of being widely available throughout the United States and is free of charge. The overall approach to treatment is based on the 12 steps for maintaining abstinence and dealing with the various effects of alcohol. AA meetings can be either "open" to anybody in the community or "closed" for active members only. The meetings vary in format, size, location, and demographic makeup. In counseling patients about attending AA, it is important for physicians to make them aware that variations in the nature of specific meetings, especially location and demographics of participants, require patients to be willing to attend more than one meeting site on a trial basis so that they find a comfortable setting.

Research on the effectiveness of AA has been limited, and there are no large controlled studies. Indirect evidence suggests, however, a significant improvement in alcohol use behaviors.

Pharmacotherapy to Prevent Relapse to Alcohol Use

The addition of medication to enhance the effectiveness of counseling therapies has been the subject of research for the past 40 years. As the neurobiology of alcohol use disorders has become more clearly understood, the potential to develop medications that may promote abstinence or decreased alcohol use has grown.[9,10] Three medications—disulfiram, naltrexone, and acamprosate—are approved for the treatment of alcohol dependence in the United States (see Table 33-5).

Disulfiram

Disulfiram is designed to prevent alcohol use by causing a severe adverse reaction when patients use alcohol. The disulfiram reaction, which includes flushing, nausea, vomiting, and diarrhea, is mediated by the inhibition of alcohol dehydrogenase and the resulting increase in serum levels of acetaldehyde and acetate after ingestion of alcohol (see Fig. 33-1). Disulfiram also affects monoamine metabolism, and the alcohol-disulfiram reaction may be related to changes in central monoamine functioning. Although disulfiram offers little benefit to most patients, it is effective in reducing alcohol intake in highly motivated patients who are supervised in an alcohol treatment program.

Naltrexone

Naltrexone is thought to decrease alcohol use by diminishing the euphorigenic effects of alcohol and by decreasing craving in alcohol-dependent patients. Randomized, placebo-controlled trials generally have shown that alcohol-dependent patients who receive naltrexone (50 mg/day) are more likely to decrease their alcohol use or remain abstinent compared with patients who receive placebo, and the effects persist after discontinuation of treatment, although one randomized trial did not show benefit in male veterans with severe alcohol dependence. Although most studies of naltrexone were performed in a specialty alcohol treatment setting and observed subjects for only 10 to 12 weeks, naltrexone also is effective in outpatient and primary care settings in patients who are followed for up to 34 weeks. Side effects of naltrexone are infrequent, most notably self-limited nausea in about 10% of patients. Dose-related hepatotoxicity has been reported in patients treated for obesity with high-dose naltrexone (300 mg/day). Mild liver enzyme abnormalities are not a contraindication to naltrexone, but patients should be followed with repeated liver enzyme studies. Patients with acute hepatitis or liver failure should not use naltrexone. In addition to the oral naltrexone, a newer long-acting injectable form of naltrexone was approved by the U.S. Food and Drug Administration (FDA) in 2006. Injectable naltrexone is typically administered at a dose of 380 mg intramuscularly every 4 weeks. Before beginning naltrexone, it is important to be sure that the patient is not opioid dependent in order to avoid a potentially severe opioid withdrawal reaction. Complete opioid abstinence for at least 7 to 10 days is recommended. Adverse reactions seen most commonly in patients who receive injectable naltrexone include injection

site reactions (e.g., induration, itching) and symptoms such as nausea and headache, which are generally self-limited. This formulation of naltrexone may be particularly effective in those with more severe alcohol use disorders.[11]

Acamprosate

Approved by the FDA in 2004, acamprosate (calcium acetylhomotaurinate) has been identified as an effective agent for treatment of alcohol dependence. The precise mechanism of action of acamprosate is uncertain but may be related to its effects on neuroexcitatory amino acids and the inhibitory GABA system. In randomized, placebo-controlled clinical trials, subjects who received acamprosate were more likely to remain abstinent compared with subjects who received placebo. Side effects are minimal and typically include diarrhea. Like naltrexone, acamprosate is given as an adjunctive therapy to psychological treatments for alcohol dependence. Acamprosate appears to be effective in both men and women.

Other Pharmacologic Approaches to Prevent Relapse

There has been much interest in evaluation of the effectiveness of combinations of drug therapies to treat alcohol dependence. One study of 160 patients suggested that the combination of naltrexone and acamprosate was more effective than either medication alone. A larger federally funded study that enrolled 1383 subjects, Project COMBINE, examined naltrexone and acamprosate alone and in combination with two different psychological therapies to see which combination of pharmacologic and behavioral therapies is most effective. The behavioral therapies were medical management, which was designed to approximate counseling that can be provided in primary care and other medical settings, and combined behavioral intervention, which incorporated counseling techniques that are provided in alcohol treatment specialty settings. Results from this study demonstrated that patients receiving medical management with naltrexone, combined behavioral intervention, or both fared best, lending further support to the idea that alcohol-dependent patients can be effectively treated in primary care and other medical settings. Interestingly, acamprosate was not shown to be effective in this study. Gabapentin is effective as a single drug therapy for treating alcohol dependence and relapse-related symptoms, such as insomnia, and the addition of gabapentin to naltrexone improves drinking outcomes in alcohol-dependent patients.

Topiramate, a fructopyranose derivative, is an effective treatment of alcohol dependence at a dose of up to 300 mg/day and is especially effective in patients with a *GRIK1* polymorphism.[12] Other medications that have shown promise include ondansetron, bromocriptine, and sodium valproate. Other drugs have shown possible benefits in patients with alcohol use disorders, perhaps more specifically those with concurrent depression (e.g., fluoxetine) or anxiety (e.g., buspirone).

PROGNOSIS

Alcohol abuse and dependence are chronic disorders that are characterized by exacerbations and remissions. The prognosis is better for patients who seek treatment and receive it in a systematic way (Table 33-6), but it can be poor for patients with advanced liver disease and continued alcohol use. In addition, the use of combinations of medications (e.g., naltrexone plus acamprosate) is under investigation.

FUTURE DIRECTIONS

To date, most studies have focused on shorter-term outcomes, from a few months to a year. It is important to understand more clearly what happens to these patients over time, especially the need for "booster sessions" to sustain improvements provided by brief interventions. Newer pharmacologic therapies may help many patients. More recently, there has been increased interest in expanding chronic care management approaches like those used in managing patients with diabetes or heart failure to patients with substance use disorders.[13] Although one large early trial failed to find a benefit, this approach may be beneficial in selected populations of patients with substance use disorders. Newer technology-based therapies, such as a smartphone application to support recovery in individuals with alcohol use disorders, hold promise for improving treatment outcomes in the future.[14]

TABLE 33-6 OVERVIEW OF TREATMENT APPROACH FOR PATIENTS WITH ALCOHOL PROBLEMS

Evaluate all patients
For patterns of problem alcohol use (Table 33-1)
For alcohol-related complications, if indicated (Table 33-2)
With use of data collected from history, physical examination, and laboratory testing (Table 33-3)
For at-risk and nondependent problem drinkers
Advise to decrease alcohol use to below at-risk levels (Table 33-4)
Advise patients who cannot decrease use to below at-risk levels to abstain
For patients who are alcohol dependent
Assess for need for withdrawal management medications (Table 33-5)
Refer to an alcohol treatment program
Consider medication to prevent relapse (Table 33-5)

REVIEW QUESTIONS

1. A 58-year-old man presents to his primary care physician's office for follow-up of hypertension. During the visit, he reports that he consumes 3 to 4 glasses (approximately 5 ounces each) of red wine every day but denies any medical, behavioral, or social problems related to his drinking. He is a nonsmoker and does not have a history of alcohol or other substance use disorders. On examination, his blood pressure is 144/96 mm Hg, his pulse is 80 beats per minute, and the remainder of his examination is unremarkable. What would be the most appropriate next step concerning his alcohol consumption?

A. Refer him to Alcoholics Anonymous.
B. Suggest that his current red wine consumption might have health benefits, but he should not drink more than this amount.
C. Prescribe naltrexone to help him stop drinking.
D. Refer him to an alcohol treatment program for counseling.
E. Advise him to decrease his consumption to no more than 2 drinks a day and reassess his alcohol use at the next visit.

Answer: E This patient exhibits "at-risk" drinking—a level of alcohol consumption that increases his risk for alcohol-related health or social problems. Randomized clinical trials have demonstrated that brief physician advice in a primary care setting can result in reduced alcohol consumption, often to levels that are below those considered to be of risk in a patient such as this (e.g., ≤2 drinks/day). In this patient's case, decreasing his alcohol use may also improve his blood pressure control. The health-related risks associated with this level of alcohol consumption are likely to far outweigh any potential (and likely minimal if any) benefit from consumption of red wine. Alcoholics Anonymous, naltrexone, and referral to an alcohol treatment program for counseling should be considered in patients who meet criteria for an alcohol use disorder, which is not the case with this patient.

2. A 30-year-old woman presents for evaluation of "shakiness." She reports several months' history of heavy alcohol consumption, typically 8 to 10 drinks per day including wine and vodka. Her presenting complaint began when she decided to quit drinking 1 day ago because she was recently placed on probation at work because of frequent tardiness related to her alcohol use. She notes that she has been drinking increased amounts of alcohol to "keep going" and that when she does try to decrease her alcohol use, especially with her recent trouble at work and some "close calls" while driving, she is unsuccessful. Which of the following best describes her alcohol consumption pattern and its related effects?

A. She is suffering from alcohol-related delirium tremens.
B. She has a severe alcohol use disorder.
C. She meets criteria for alcohol abuse.
D. She has a mild alcohol use disorder.
E. She is not a binge drinker.

Answer: B This patient meets at least six of the DSM-5 criteria for an alcohol use disorder and thus would be considered in the severe category. Her presentation as described includes several of these criteria: evidence of tolerance, withdrawal, more use than intended, unsuccessful attempts to cut down, tolerance, use despite negative effects, failure to fulfill a major role obligation, and use in hazardous situations. Although she does present with symptoms likely related to alcohol withdrawal, there is nothing in the presentation to suggest delirium tremens. *Alcohol abuse* is a term from earlier versions of DSM and is no longer used as diagnosis. Patients with a "mild" alcohol use disorder have only two or three of the DSM-5 criteria. She does not meet criteria for binge drinking.

3. The same 30-year-old woman described in question 2 eventually develops severe enough withdrawal symptoms to be hospitalized for the medical management of her alcohol withdrawal. Which of the following is true concerning the course of her alcohol withdrawal?

A. If present, withdrawal seizures are likely to occur between 48 and 72 hours after the last drink.
B. Chlordiazepoxide and diazepam are the only benzodiazepines that have been approved by the FDA for the treatment of alcohol withdrawal.
C. Benzodiazepines have been demonstrated to effectively reduce the occurrence of alcohol withdrawal seizures.
D. Longer acting benzodiazepines are always preferred to those that are shorter acting.
E. β-Blockers are an effective alternative to benzodiazepines for the treatment of alcohol withdrawal.

Answer: C Benzodiazepines are the treatment of choice for the alcohol withdrawal syndrome. There is strong evidence that they decrease the frequency of alcohol withdrawal seizures, and numerous randomized trials have demonstrated their effectiveness in controlling withdrawal-related symptoms and vital sign abnormalities. Alcohol withdrawal seizures tend to occur within 12 to 24 hours after alcohol consumption is reduced or stopped. There are four benzodiazepines that have been approved by the FDA—in addition to the two mentioned in choice B, oxazepam and lorazepam are also FDA approved. Short-acting benzodiazepines may be preferred in patients with severe liver disease. β-Blockers are effective adjuncts to benzodiazepines in the treatment of alcohol withdrawal but should not be used alone as an alternative to benzodiazepines.

4. The same 30-year-old patient presented in questions 2 and 3 is discharged from the hospital after successful treatment of the alcohol withdrawal syndrome. Which of the following is the appropriate "next step" in the management of her alcohol-use disorder?

A. Assess her motivation to remain alcohol free and determine her interest in receiving treatment for relapse prevention.
B. Refer her to the Alcoholics Anonymous program that your father went to.
C. Continue her benzodiazepines as an outpatient to help her stay away from alcohol.
D. Discharge her on disulfiram and see her back in your office in a month.
E. Advise her to abstain from alcohol and see her back in your office in a month.

Answer: A The first step in managing patients with alcohol use disorders who have been successfully detoxified is to assess their motivation to remain alcohol free and discuss various follow-up treatment options in order to assess their interest in treatment and help identify the best approach to getting relapse prevention therapy. Patients who are suitably motivated and interested in engaging in ongoing treatment should then be referred as appropriate. Those who are not ready to accept treatment may benefit from motivational interviewing approaches and close follow-up in order to engage them in treatment in the future. Alcoholics Anonymous may be helpful to many patients; however, without assessing a patient's motivation, it is difficult to tell if such a referral will be followed. In addition, AA meetings differ in terms of their content and membership, and patients may need to try several meeting sites to find a group that they are comfortable with. Benzodiazepines are not indicated for the prevention of relapse to alcohol use. Disulfiram has been shown to be effective in highly motivated patients who receive treatment in a highly supervised manner. There is no evidence that brief advice alone is effective in the treatment of alcohol use disorders.

5. A 47-year-old man presents to his primary care physician for a routine preventive health visit. He has a history of an alcohol use disorder and has been hospitalized three times for alcohol withdrawal, is participating in Alcoholics Anonymous, and is currently getting cognitive behavioral therapy from a therapist. Despite this, he continues to struggle with craving for alcohol and has had numerous relapses interrupting episodes of sobriety. He has heard about medications that might help him prevent these relapses and would like to try something. Which of the following is the most appropriate recommendation?

A. Don't use a relapse prevention medication because this will be frowned upon by his Alcoholics Anonymous group.
B. Give him a prescription for disulfiram and ask him to follow up in 3 months.
C. Start with a combination of naltrexone and acamprosate because this will yield the best results.
D. Consider the use of intramuscular naltrexone, 380 mg per month.
E. Prescribe topiramate, 300 mg a day.

Answer: D In several clinical trials, naltrexone has been demonstrated to decrease alcohol consumption in individuals who are dependent on alcohol. Although generally well tolerated, contraindications include current opioid dependence and severe liver disease. Although it is true that some Alcoholics Anonymous participants or groups may frown upon the use of medication to treat alcohol use disorders, this is not a reason to not use these medications. However, patients should be made aware of this possibility and counseled on how to deal with this if it occurs. Disulfiram has been shown to be effective in highly structured treatment programs. Although it may be helpful in some primary care patients, there is no evidence that it is effective when used by primary care physicians in an unstructured manner. There is no significant evidence that combinations of relapse prevention medications improve outcomes in patients who are dependent on alcohol. Topiramate has been demonstrated to be effective in preventing relapse to alcohol use in some studies, but it is not yet approved for this indication.

34

DRUGS OF ABUSE

ROGER D. WEISS

DEFINITION

The term *substance use disorder* has replaced *substance abuse* and *dependence* in the diagnostic lexicon; recent research has shown that the previous hierarchical distinction between abuse and dependence, with dependence representing a more severe form of the disorder, was problematic and not warranted. A substance use disorder is a clinical syndrome characterized by the following statement from the fifth edition of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders*: "The essential feature of a substance use disorder is a cluster of cognitive, behavioral, and physiological symptoms indicating that the individual continues using the substance despite significant substance-related problems."[1] There is no single pathognomonic symptom that is diagnostic of a substance use disorder. Rather, the syndrome is a series of 11 symptoms, of which the individual needs to meet two or more in the same 12-month period to warrant a diagnosis of a substance use disorder (Table 34-1). These 11 symptoms can be grouped into four general categories:

Impaired control: taking a substance in larger amounts or for a longer time than intended; persistent desire or unsuccessful attempts to stop or to reduce use; a great deal of time spent using a substance or recovering from the effects of its use; craving

Social impairment: failure to fulfill role obligations at home, work, or school as a result of repeated substance use; continued substance use despite experiencing interpersonal problems; or reducing or giving up important social, recreational, or occupational activities

Risky use: recurrent use in hazardous situations (e.g., driving) or despite knowledge that substance use is causing or exacerbating a physical or psychological problem

Pharmacological criteria: tolerance and physical dependence, when relevant; not all drugs cause these symptoms

For people who are prescribed medications that can cause tolerance and physical dependence, the diagnostic term *substance use disorder* should be used only with people whose medication use is problematic; tolerance and physical dependence are not considered criteria for a diagnosis of a substance use disorder in patients who are taking medications such as opioids or

TABLE 34-1 DSM-5 CRITERIA FOR SUBSTANCE USE DISORDERS

IMPAIRED CONTROL
1. Took larger amounts/for longer period of time than intended
2. Persistent desire or unsuccessful attempts to stop or reduce use
3. Much time spent using a substance or recovering from its effects
4. Craving
SOCIAL IMPAIRMENT
5. Failure to fulfill home, work, or school obligations because of repeated substance use
6. Continued use despite experiencing interpersonal problems
7. Reducing/giving up important social, recreational, or occupational activities
RISKY USE
8. Recurrent use in hazardous situations
9. Physical/psychological problems related to use
PHARMACOLOGICAL CRITERIA
10. Tolerance, when relevant*
11. Physical dependence, when relevant*

Substance use disorder is diagnosed if two or more of these 11 criteria are met within a 12-month period.
*"When relevant" indicates that these criteria are not counted, even if the symptoms are present, when an individual is using legitimately prescribed medications as intended and those medications are helping the person to function better.
From Hasin DS, O'Brien CP, Auriacombe M, et al. DSM-5 criteria for substance use disorders: recommendations and rationale. *Am J Psychiatry.* 2013;170:834-851.

sedative-hypnotics exclusively as part of appropriate medical care. If someone is using legitimately prescribed medications as intended (e.g., opioids for chronic pain or benzodiazepines for panic disorder) and those medications are helping the person to function better, that person will not meet criteria for a substance use disorder, even if the person is tolerant to the medication and is physically dependent.

EPIDEMIOLOGY

Use of illicit drugs and non-medical use of prescribed drugs are common. In 2011, approximately 22.5 million Americans reported using an illicit drug in the previous month, representing approximately 9% of the population. When asked about their substance use in the past month, 18 million people reported using marijuana, 6 million reported using potentially psychoactive prescription drugs nonmedically, 1.4 million people used cocaine, and 1 million people used hallucinogens; in fact, 10% of youths aged 12 to 17 years reported using an illicit drug in the past month. Illicit drug use is an important contributor to the global burden of disease, accounting for 20 million disability-adjusted life years in 2010. Worldwide, more people were dependent on opioids and amphetamines than other drugs.[2] Drug abuse produces substantial medical morbidity and mortality as well as tremendous social and economic costs.

PATHOBIOLOGY

Drug use disorders involve complex interactions between the pharmacology of a specific drug, an individual's genetic makeup, psychological strengths and weaknesses, environmental circumstances, and societal influences (such as physical and perceived drug availability, legal status and cost of the drug, religious and cultural mores, and presence of alternative rewarding activities). Thus, one can conceptualize the etiology of drug abuse by employing the public health model frequently cited in the study of infectious disease, that is, as an interaction among the host (i.e., the potential drug user), the agent (a specific drug in this case, as opposed to an infectious microorganism), and the environment (the person's family life and peer group and the social, cultural, and religious attitudes toward use of that substance).

The Host

A host factor that is well known to heighten vulnerability to drug abuse problems is a positive family history of a substance use disorder, which has been shown to increase the likelihood of development of both alcohol and drug dependence. Twin studies and adoption studies have shown that both genetic and environmental factors contribute to this vulnerability, although the precise nature by which this occurs is still unknown and a subject of active research. One area of great research interest relates to whether people can be vulnerable to drug dependence in general (e.g., as a result of a risk-taking temperament or poor decision making) or whether they are at high risk to abuse particular substances (perhaps because of a highly reinforcing response to a specific drug).

Psychiatric illness has been shown to influence the likelihood for development of drug abuse problems. For example, conduct disorder in childhood and adolescence and antisocial personality disorder in adulthood have both been found to predispose to subsequent drug abuse problems. Psychiatric disorders such as mood disorders are frequently noted in people with drug abuse problems. However, the presence of these two disorders in the same person does not necessarily imply causation, even if one of the disorders is manifested first.

In addition to the risk factors mentioned previously, certain individual protective factors may reduce the likelihood of a substance use disorder. Individuals who have positive familial relationships, success in academic activities, and meaningful religious affiliations have a lower likelihood for development of drug problems. The fact that many people have a mixture of risk and protective factors speaks to the complex etiologic nature of drug use disorders.

The Agent

Most drugs of abuse are inherently reinforcing; animals typically will self-administer most of the commonly abused drugs. Not all drugs are equally reinforcing in general, however, and there is a great deal of individual variation in drug preference. Some people like the stimulating effects of drugs such as cocaine and amphetamine, whereas others experience that level of stimulation as extremely uncomfortable. Some people like the relaxation induced by drugs such as marijuana and sedative-hypnotics, whereas others feel deadened and overly slowed down by these drugs. Although some people gravitate toward particular drugs of abuse because of their specific pharmacologic properties, other will use a variety of drugs indiscriminately, based on level of availability; some of these people are primarily seeking to alter their current emotional state, regardless of the direction in which it is changed. The reinforcing properties of many drugs of abuse appear to be mediated through dopaminergic pathways, although other neurotransmitters, including γ-aminobutyric acid, serotonin, and norepinephrine, are also involved in mediating drug-induced reinforcement.

The Environment

The third critical factor in the development, maintenance, and perhaps cessation of drug abuse is the environment in which the use occurs. Drug use does not occur in a vacuum. Rather, many societal factors, including legal status, availability, price, perception of dangerousness, social desirability, peer group, and religious beliefs, influence behavior relating to substance use. Drug availability is known to be a substantial influence on likelihood of substance use. For example, alcohol consumption has been shown to increase when the hours during which alcohol can be sold are extended. The restriction of alcohol availability by restricting hours of sale or by increasing its cost through taxation in turn reduces consumption. Illicit drugs are, of course, by definition less available than alcohol or tobacco. A major factor that influences use of these agents is the potential user's perception of the drug's safety, social cachet (or lack thereof), likelihood of incurring legal consequences, and peer group behavior. Treatment research has shown that environmental influences can have a powerful effect on drug use. Studies have shown, for example, that offering an alternative positive reward (e.g., a voucher that can be exchanged for desired goods and services such as movie tickets or clothes) in response to abstaining from drugs may help drug-dependent individuals overcome their severe craving and reduce their substance use. In fact, this type of treatment approach, based on the use of motivational incentives for abstinence, has been shown to be one of the most powerful treatment interventions available for the treatment of drug use disorders. The impact of environmental contingencies demonstrates the importance of appreciating the complexity of the interaction among the individual, the drug, and the environment in the determination of drug use.

CLINICAL MANIFESTATIONS

Medical Complications Related to Drug Use Disorders

Drug use disorders are associated with significant medical morbidity and sometimes with mortality. Medical complications are often directly related to the pharmacology of the abused agent, for example, the vasoconstrictor properties of cocaine; drug-specific complications are described later in the sections focusing on particular drugs of abuse.

In addition to these drug-specific sequelae, however, many medical complications incurred by patients with drug use disorders occur not as a result of the particular drug being abused. Rather, serious complications may occur as a result of three factors that cut across many of the drugs of abuse: paraphernalia, particularly unsterile needles; adulterants; and lifestyle issues.

Paraphernalia

Some of the most serious medical problems that occur in individuals with drug use disorders are a result of the route of administration rather than of the actual drug being used. The use of unsterile needles, particularly if they are shared with other drug users, can lead to a variety of localized and systemic infections, some of which can be life-threatening. Skin infections and cellulitis are relatively common among injection drug users. Systemic infections related to needle use are often serious; individuals who inject drugs may develop infective endocarditis (Chapter 76). Other relatively common infections among injection drug users include hepatitis B, hepatitis C, and HIV infection.

Adulterants

Drugs that are purchased and sold illicitly are often adulterated or "cut" with other similar-looking products, with the intention of increasing the dealer's profit margin. For example, other white powdery substances are typically added to cocaine and heroin during the dealing process to dilute their purity. Some of these adulterants can in turn cause medical problems.[3] At times, these complications occur because of the combined toxicity of the adulterant and the route of administration. Thus, for example, a patient may have granulomas in the lung or liver as a result of talc use; talc is commonly added to street heroin and can also cause difficulties in users who crush talc-containing pharmaceutical tablets (e.g., opioids) and then inject them. Other common adulterants in street drugs include quinine (frequently used with heroin) and lidocaine or levamisole (often added to cocaine), but such toxic materials as strychnine and ground glass have been found in samples of street drugs, leading to serious medical sequelae.

Lifestyle Issues

Many patients with drug use disorders expose themselves to multiple risks due to intoxication, participating in dangerous illegal activities, and associating with potentially violent people. As a result, these individuals experience a high rate of traumatic injuries and are at greater risk of being victims of assault, homicide, or suicide. Suicide is far more common among people with substance use disorders than among the general population; this may be related to a combination of the effects of acute intoxication, the high prevalence of depression among these individuals, and the higher rate of antisocial personality disorder in this population, which is associated with a propensity toward impulsiveness, risk taking, and violence. Although it is well known that intoxication can lead to motor vehicle crashes, intoxication can also serve as a risk factor for becoming a victim of someone else's vehicle; one study reported that one third of pedestrians who are killed by motor vehicles have alcohol in their blood, perhaps a reflection of the combination of risk taking, poor judgment, and impaired motor coordination that can occur during periods of intoxication.

TREATMENT

General Treatment Principles

Drug use disorders represent a heterogeneous group of disorders. These are based on type of drug or drugs used; frequency and amount of use; severity of medical, behavioral, and social consequences; presence and severity of comorbid medical and psychiatric illness; and motivation to change. Treatment thus requires a careful medical and psychiatric assessment, including a detailed substance use history and laboratory testing. It is often helpful to enlist the help of a family member or significant other (with the patient's permission) in obtaining historical information. Intoxication and withdrawal syndromes need to be treated acutely; longer-term treatment involves helping the patient reduce or ideally abstain from substances of abuse and thus improve overall functioning.

Among the common drugs of abuse, medications with approval by the U.S. Food and Drug Administration (FDA) are available only for opioids and nicotine (nicotine is discussed in Chapter 32). However, researchers are actively studying a number of compounds for the treatment of other drugs of abuse, particularly stimulants and marijuana. Behavioral treatments are critically important in the treatment of substance use disorders. A number of behavioral treatments have a substantial evidence base supporting their efficacy; these include cognitive-behavioral therapy, motivational enhancement therapy, contingency management (also referred to as motivational incentive) therapy, 12-step facilitation therapy, and behavioral couples therapy. In addition to professional treatment, peer support groups such as the 12-step–oriented Alcoholics or Narcotics Anonymous and non–12-step groups such as SMART Recovery can be extremely helpful in facilitating recovery from drug abuse problems.

MAJOR DRUGS OF ABUSE

Opioids

For centuries, opioids have been a core part of the medical pharmacopoeia, primarily because of their capacity to treat pain but also because of their antitussive and antidiarrheal properties. Unfortunately, opioids are also powerful euphoriants and thus have substantial abuse liability. Although opium itself has been used for centuries, the isolation of morphine and codeine from opium in the 19th century along with the introduction of the hypodermic needle led to the increased prevalence of intravenous opioid use. Ironically, heroin was introduced near the end of the 19th century as a treatment for morphine addiction.

Opioids can be divided into four categories: natural opium alkaloids, including opium, morphine, and codeine; semisynthetic derivatives of morphine, including heroin and oxycodone; synthetic opioids that are not derived from morphine, including methadone and meperidine; and opioid-containing preparations, such as elixir of terpin hydrate.

EPIDEMIOLOGY

Opioid dependence represents a significant public health problem and accounts for more admissions for substance use disorder treatment than any substance other than alcohol. In the past two decades, there has been a shift in the epidemiology of opioid use disorders, however, with a reduction in heroin use and an increase in the abuse of opioid analgesic drugs; the latter has occurred as a result of either misuse of prescription opioids or illicit use of these agents. Approximately 620,000 people in the United States reported using heroin in 2011, with 178,000 trying the drug for the first time. During the same year, more than 11 million people either misused prescription opioids or used them illicitly, with 1.9 million doing so for the first time; opioids are currently the most commonly misused prescription drugs. Most people who use opioid analgesics in this way report that they initially obtained them from a friend or relative. It is thus likely that a portion of these people might, for example, have used a relative's opioid for the treatment of a temporary painful condition such as a migraine headache. However, the number of people seeking treatment as a result of an opioid analgesic use disorder has increased dramatically in the past decade.

PATHOBIOLOGY

Opioids are readily absorbed when they are taken orally, intranasally, or by smoking or injection. Heroin, which is almost immediately converted to morphine in the liver, is most commonly injected but may be smoked or used intranasally.

Opioids work by binding to specific opioid receptors and then exerting their activity. The major subtypes of opioid receptors have been identified and well described. Most of the commonly abused opioids bind as agonists to the μ-receptor and typically produce the effects most commonly associated with opioids: miosis, respiratory depression, analgesia, euphoria, and drowsiness. Opioids that bind to the κ-receptor, unlike μ-receptor agonists, often produce dysphoria rather than euphoria. The other two receptors, δ- and N/OFQ-receptors, do not appear to play a known significant role in opioid use disorders.

Opioid analgesics are ordinarily taken by the oral route, but they may be altered to be used through a different route of administration. This is particularly common with the extended- release preparations, which may be altered by chewing the pill (facilitating a rapid release of the opioid medication) or by crushing the pill, dissolving it in water, and then injecting it or using it intranasally.

CLINICAL MANIFESTATIONS

The initial response to the administration of heroin, particularly when it is used intravenously, is a "rush," often described as orgasmic, lasting 30 to

60 seconds. This sensation is generally followed by a profound sense of relaxation that is sometimes referred to as being "wrapped in warm cotton." During this period, the user generally feels drowsy and may be seen to be "nodding," with mental clouding and a sense of tranquility. A reduction in respiratory rate occurs, along with miosis, reduced contractility of smooth muscle, and reduced secretions in the stomach, pancreas, and biliary tract. Thus, constipation and urinary hesitancy may occur. Itching is commonly seen during opioid intoxication. Many people experience nausea and vomiting in their initial use of opioids, although tolerance tends to develop to this effect over time. Tolerance also occurs to some other effects rather quickly, particularly the analgesic, respiratory depressant, and euphoriant properties of opioids. In contrast, relatively little tolerance occurs to constipation or to pupillary constriction. It is important to be aware, then, that miosis is a manifestation of opioid use, but it is not diagnostic of opiate overuse or intoxication.[4]

Physical Dependence

Physical dependence on opioids leads to a characteristic withdrawal syndrome, the key signs of which include elevated heart rate and blood pressure, mydriasis, abdominal cramps, sweating, gooseflesh, rhinorrhea, lacrimation, and gastrointestinal distress, particularly diarrhea, nausea, and vomiting. Insomnia is common, particularly difficulty in falling asleep; this is often the most long-lasting complaint among people who experience opioid withdrawal. Yawning, muscle twitches, and difficulty with body temperature regulation are also commonly seen. The severity of withdrawal can be highly variable, depending on the dose of opioids taken, the length of time that they have been taken, and individual factors. For short-acting opioids such as heroin and hydrocodone, the earliest stages of withdrawal typically occur approximately 6 to 12 hours after the last use. Peak symptoms tend to occur 48 to 72 hours after the last dose, and most clinical symptoms usually resolve within 7 to 10 days. For longer-acting opioids such as methadone, each of these time periods associated with withdrawal from short-acting opioids should be approximately doubled or tripled.

Other Medical Complications

The most common serious medical complications that occur from opioid use are typically related to factors other than the opioids themselves, particularly needle use and adulterants; these were discussed previously. Common medical problems among heroin users include hepatitis B, hepatitis C, infective endocarditis, talc granulomatosis, HIV infection, cellulitis, and abscesses, all typically related to needle use.

An important noninfectious complication that has been reported with opioid use disorders is alteration of the cardiac conduction system, with a prolongation of the QT interval; this can lead to potentially serious arrhythmias, including torsades de pointes. This complication has been particularly noted with methadone.

Chronic pain is commonly seen among individuals with opioid use disorders, not just those who have received opioids for the treatment of pain. Pain can occur in these individuals for numerous reasons. In addition to the possibility that a chronic painful condition led to the use of opioids in the first place, those dependent on opioids are more likely to experience accidents, violence, and other forms of physical trauma that could produce chronic pain. There is also some evidence that chronic opioid use may lead to hyperalgesia, although there is some controversy regarding this issue. As with all substance use disorders, psychiatric illnesses (particularly mood disorders) are more common in those with opioid use disorders than in the general population. Moreover, the use of multiple drugs is common in patients with opioid use disorders, particularly among those using heroin. Indeed, the use of more than one drug is typically the rule rather than the exception in most substance use disorders.

TREATMENT

Opioid Withdrawal

Opioid detoxification can be accomplished by switching patients from their current drug of abuse (e.g., heroin, hydrocodone) to methadone or buprenorphine and then tapering that medication. Although the details of accomplishing this vary, one method commonly used in hospital settings is to administer methadone 10 mg orally whenever a patient experiences objective signs of opioid withdrawal (e.g., mydriasis, tachycardia, hypertension, and sweating). This process can be repeated every 2 to 4 hours for 24 hours after the initial dose; the total amount of methadone given in that 24-hour period is the "stabilization dose," which should not ordinarily exceed 40 mg. The stabilization dose is then reduced by 5 mg a day until the detoxification is completed.

Buprenorphine can also be used successfully for opioid detoxification[■]; patients who demonstrate objective signs of opioid withdrawal (often measured with a standardized withdrawal severity scale) can be stabilized with buprenorphine during a 1- to 2-day period; the subsequent taper from buprenorphine may occur either right away or after a period of stabilization with buprenorphine. The dose of buprenorphine will depend on whether the medication will be used for a brief, several-day detoxification or for longer-term stabilization or maintenance treatment.

Longer-Term Opioid Dependence Treatment

Three effective medications are approved by the FDA for the treatment of opioid dependence: methadone (a full opioid agonist), buprenorphine (a partial agonist), and naltrexone (an opioid antagonist). Methadone has been used successfully for both detoxification from opioids and maintenance treatment for many years.[■] Unlike buprenorphine and naltrexone, which can be prescribed by physicians in their offices (although physicians wishing to prescribe buprenorphine for the treatment of opioid dependence must receive specialized training and certification to do so), methadone is available for the treatment of opioid dependence only in specially licensed treatment programs. Methadone is a long-acting μ-receptor agonist with a slow onset of peak effects (typically approximately 2 to 6 hours) and a slow offset of action, allowing for once-a-day administration. Methadone reduces opioid craving and induces cross-tolerance, thus blocking or attenuating the effects of other opioid use. Although the therapeutic dose of methadone for a particular individual may vary, doses of 60 mg or higher have typically been shown to be more effective than lower doses; there is some evidence that even higher doses (e.g., 80 mg a day or more) may be more effective than 60 mg. Methadone treatment has been shown to reduce opioid use, to increase employment, to decrease criminal behavior, and to reduce the rate of development of HIV infection.

When a patient enrolled in a methadone treatment program experiences pain (e.g., postoperatively) requiring opioid analgesia, the patient should continue to receive the baseline methadone maintenance treatment dose for the addiction and should receive a different opioid for treatment of the pain (Chapter 30); before administering methadone, it is a good idea to confirm the methadone dose with the patient's treatment program. The fact that the patient is receiving methadone every day does not obviate the need for opioid analgesia, however. In fact, many patients receiving methadone treatment for opioid dependence will require a dose of opioids that is relatively high as a result of cross-tolerance to other opioid drugs.

The Drug Addiction Act of 2000 revolutionized the treatment of opioid dependence by enabling the approval of the partial opioid agonist buprenorphine for the treatment of opioid dependence and allowing treatment with buprenorphine to be administered in physicians' offices rather than exclusively in specialized opioid treatment programs. To prescribe buprenorphine, physicians must apply to the Substance Abuse and Mental Health Services Administration for a waiver that allows them to prescribe buprenorphine, after taking an 8-hour training course on buprenorphine. At the time of this writing, physicians may treat up to 100 patients with buprenorphine in their office practice. Buprenorphine, a partial μ-agonist and κ-antagonist, has a more favorable safety profile than methadone because of its partial agonist properties. Respiratory depression, which can be induced by full agonists and is responsible for some overdose deaths, is far less likely to occur with buprenorphine because its partial agonist properties cause a plateau of opioid effects as the dose increases. Buprenorphine is administered sublingually, in either tablet or film form, for the treatment of opioid dependence either as buprenorphine alone (sometimes referred to as the "mono" product) or (more commonly, in the United States) as a combination product of buprenorphine and naloxone; the naloxone is added to discourage users from dissolving and injecting the medication because the naloxone in the combination product will precipitate withdrawal when it is injected. Buprenorphine has been shown to be effective for both opioid detoxification and maintenance treatment. Randomized trials have shown that extended treatment with buprenorphine-naloxone has produced far better outcomes compared with short-term detoxification in opioid-addicted youths aged 15 to 21 years.[■] Typical doses of 12 to 16 mg of sublingual buprenorphine per day appear to be as effective as methadone in doses up to approximately 60 mg a day. Buprenorphine is also effective for maintenance therapy of heroin addiction[■], but individuals who require much higher doses of methadone may respond better to that agent than to buprenorphine.[■] To address problems with adherence, diversion, and nonmedical use, an implantable formulation of buprenorphine has been developed that provides a low, steady level of the drug during 6 months.[■]

Naltrexone, a pure opioid antagonist, blocks the effects (including euphoria) of opioids. As a result, individuals taking naltrexone should have a reduced desire to use opioids because they will have no desired effect. When it is used orally (50 mg/day) or in its long-acting form (380 mg intramuscularly every 4 weeks), naltrexone is highly effective at suppressing illicit opioid use. A

randomized clinical trial in prescription opioid-dependent outpatients has also demonstrated the effectiveness of naltrexone maintenance after buprenorphine taper. However, naltrexone has traditionally suffered from low acceptability; few patients have been interested in being treated with oral naltrexone. Moreover, among those who initially accept this treatment, the dropout rate is extremely high. An advantage of extended-release injectable naltrexone is that it can mitigate the traditionally poor adherence associated with the oral formulation; naltrexone can be a useful medication for patients who are willing (either as the result of external pressure or for internal motivation) to use it.

Methadone, buprenorphine, and naltrexone are not designed to be delivered alone but should be given in conjunction with counseling to be effective. It has been well demonstrated that the administration of methadone in the absence of counseling is an inadequate treatment approach; less is known about the optimal combination of buprenorphine and counseling. Two studies have demonstrated that counseling delivered within a medical office setting can be effective in conjunction with buprenorphine treatment, suggesting that general physicians who are trained to use buprenorphine can effectively treat at least a portion of patients with opioid dependence in their offices with a combination of buprenorphine and counseling.

Central Nervous System Stimulants: Cocaine and Amphetamines

The two most important central nervous system stimulants, cocaine and amphetamine (including methamphetamine[5]), are derived from different sources; cocaine is extracted from coca leaves, whereas amphetamine is a synthetic compound. However, both induce similar psychoactive activity when they are taken illicitly and can produce similar adverse consequences. Amphetamine has been used over the years to treat obesity and to combat fatigue and depression. Cocaine is still used as a topical anesthetic for otolaryngologic surgery. Ironically, its vasoconstrictor action, which is responsible for many of the cocaine-related medical complications described later, can be valuable for surgeons because of the resultant reduction of blood flow in the operating field. Although cocaine was not extracted from the coca leaf until the 19th century, coca leaves have been chewed for more than 1500 years for medicinal and religious purposes as well as to combat work-related fatigue. Sigmund Freud was one of the foremost advocates of cocaine, both extolling its psychoactive properties and discovering its ability to relieve pain, thus eventually leading to its discovery as the first local anesthetic. Cocaine was seen in the late 19th century as a "cure-all" and was included in numerous patent medicines as well as in Coca-Cola. The Harrison Narcotic Act of 1914 restricted the use of cocaine, and the drug was not widely used until the late 1970s, when there was a resurgence in cocaine use in the United States.

Like cocaine,[6] amphetamine was synthesized for the first time in the late 19th century. It was used for clinical purposes for the first time in the 1920s. Reports of amphetamine abuse first occurred in the 1930s, with intermittent epidemics since that time. In recent years, methamphetamine[5] abuse has been particularly prevalent and worrisome in the United States, with particularly high concentration of its use in the Midwestern and Western states, including Hawaii.

Cocaine can be used intranasally, by intravenous injection, or by smoking. Cocaine hydrochloride, which is the form of the drug used in medical therapeutics, is a water-soluble compound that can be used intranasally ("snorted") or injected. Adding an alkaline compound such as baking soda to an aqueous solution of cocaine hydrochloride produces a rocklike compound known as crack, which can be smoked. Smoking cocaine produces the most rapid onset of intoxication (6 to 10 seconds) and the shortest period of drug effect (10 to 15 minutes). Methamphetamine can also be used in multiple ways—orally, by smoking, or intravenously. Methamphetamine effects last much longer than those produced by cocaine; psychiatric symptoms such as paranoia that typically last only a matter of hours in cocaine users may persist for days to weeks after methamphetamine use and occasionally may result in a chronic psychotic state.

EPIDEMIOLOGY

Approximately 37 million Americans have used cocaine during their lifetime. In 2011, just less than 4 million people used cocaine; 1.4 million people, or 0.5% of the population, reported using cocaine in the past month. Of these past-month cocaine users, 17% (228,000) used crack, a decrease from 2010. Cocaine had the third highest rate of drug abuse or dependence in 2011 and was the third most common drug (behind opioids and cannabis) associated with a recent treatment episode; cocaine is also the drug of abuse most commonly involved in emergency department visits.

Other stimulant use is less common; approximately 20 million Americans have used stimulants nonmedically during their lifetime, with 12 million methamphetamine users. Methamphetamine use in the past month is reported by more than 400,000 people in the United States.

PATHOBIOLOGY

Both cocaine and amphetamine increase the accumulation and activity of specific neurotransmitters in the synaptic cleft, including dopamine, norepinephrine, and serotonin. Cocaine is believed to exert this effect by binding to the dopamine transporter. Increased dopaminergic activity, particularly in the nucleus accumbens, is thought to be responsible for the reinforcing effects of cocaine. Amphetamines appear to increase the level of dopamine in the synaptic cleft primarily by stimulating presynaptic dopamine release as opposed to reuptake blockade.

CLINICAL MANIFESTATIONS

Both cocaine and amphetamines reliably produce euphoria, wakefulness, a sense of initiative, increased self-confidence (sometimes to the point of grandiosity), and, in some instances, sexual stimulation. With higher doses, users may feel "wired," a syndrome characterized by anxiety, irritability, and perhaps paranoia. Withdrawal from either of these agents leads to opposite effects from those of intoxication: increased appetite, hypersomnia, and depression, which can occasionally be serious. Medical complications related to cocaine use[6] are related to a combination of cocaine's stimulant activity (increased heart rate and blood pressure) and its vasoconstrictor properties. Local complications that result from the drug's vasoconstrictor activity include ulcerations of the nasal mucosa, perforation of the nasal septum, and decreased pulmonary diffusion capacity. Systemic complications include myocardial infarction, intracranial hemorrhage, grand mal seizures (as a result of intoxication, not withdrawal), and ventricular tachyarrhythmias, which may be responsible for sudden death. Physicians seeing a patient in an emergency department for an unexplained seizure should consider drug abuse as a potential cause. (Not only cocaine but also phencyclidine and meperidine intoxication may lead to seizures, as can sedative-hypnotic or alcohol withdrawal). A serum or urine toxicology screen may thus be an important diagnostic tool in such a situation.

TREATMENT

Rx

The treatment of stimulant use disorders primarily consists of behavioral therapies, including individual and group therapy, and self-help groups. Specific forms of treatment, such as cognitive-behavioral therapy, individual drug counseling by a 12-step–oriented disease model, and a behavioral treatment in which patients are reinforced for positive outcomes (e.g., drug-free urine screens), have been found to be successful. A great deal of research has been conducted in search of an effective pharmacotherapeutic treatment for stimulant dependence, but there is as yet no medication that has consistently been found to be effective enough to warrant approval by the FDA for this purpose.

Sedative-Hypnotic and Anxiolytic Drugs

Benzodiazepines and other sedative-hypnotic and anxiolytic medications such as barbiturates and zolpidem are frequently prescribed for the treatment of anxiety and sleep difficulties. Although different classifications of these drugs have very different chemical structures, they are grouped together according to their therapeutic applications. Most of these drugs act at the γ-aminobutyric acid type A receptor and can cause physical dependence and both dispositional and pharmacodynamic tolerance.

Because the benzodiazepines are far and away the most commonly prescribed sedative-hypnotics, they are also the most widely abused. There are two major patterns of benzodiazepine abuse. Many people who ultimately abuse these medications have initially received a legitimate benzodiazepine prescription for the treatment of anxiety or insomnia. However, a combination of tolerance and decreased effectiveness of the agent over time may lead some people to increase the dose on their own. In such circumstances, attempts by the physician to taper the person off of the medication can be very difficult.

A second pattern of benzodiazepine abuse occurs among individuals who are using other drugs of abuse, most commonly opioids or stimulants. For example, many individuals who are dependent on heroin or other opioids

may use benzodiazepines as a means of either enhancing the opioid effect or buffering symptoms of opioid withdrawal. Such individuals typically use relatively large doses of benzodiazepines intermittently, and therefore many of these patients do not develop physical dependence on benzodiazepines, unlike the first category of patients, for whom physical dependence is common.

TREATMENT

The treatment of people who are abusing benzodiazepines depends to some extent on the pattern of abuse. For individuals who have an anxiety disorder and have been misusing a legitimately prescribed medication, a common approach would be to taper the benzodiazepine and to institute a different type of treatment, such as an antidepressant along with cognitive-behavioral therapy. Tapering a benzodiazepine that a person has been taking for an extended time (sometimes many years) is often a slow process, with careful monitoring of withdrawal symptoms (anxiety, agitation, insomnia, tachycardia, palpitations). Because benzodiazepine withdrawal, like alcohol withdrawal, can precipitate a seizure, gradual withdrawal is preferred. Most patients tolerate a benzodiazepine dose reduction initially with relatively little difficulty. However, as with most drug withdrawal regimens, people experience their greatest discomfort toward the end of the taper. One reason for this is that the percentage dose reduction at the low end of a taper regimen continues to increase over time; a reduction from 2 mg to 1.5 mg of clonazepam, for instance, is a 25% reduction, whereas the same half-milligram dose reduction from 1 mg to 0.5 mg represents a 50% drop.

For patients who are abusing benzodiazepines as part of a pattern of multiple substance use, medical detoxification from the benzodiazepine itself will often be unnecessary; for this population, psychosocial approaches that advocate abstinence from all substances of abuse, in conjunction with appropriate pharmacotherapy as needed (e.g., in the case of opioid dependence), are preferred. However, some deaths have been reported in France and elsewhere as a result of combinations of buprenorphine and benzodiazepines, usually used parenterally. Thus, physicians who are treating patients who are abusing both opioids and benzodiazepines need to be mindful of this issue when considering the use of buprenorphine.

Marijuana

Marijuana, which refers to the dried leaves and flowers of the plant *Cannabis sativa*, has been used for its psychoactive and medicinal properties for centuries. The major psychoactive substance in marijuana is Δ^9-tetrahydrocannabinol (THC); the concentration of THC has increased from 1 to 3% in 1970 to nearly 10% in recent years.

EPIDEMIOLOGY

Marijuana is the most commonly used illicit drug in the United States; more than 120 million Americans have used marijuana, and approximately 22 million report that they have used marijuana in the past month. With the recent trend toward legalization of medical marijuana and outright legalization of marijuana in some states, those numbers will likely continue to increase.

PATHOBIOLOGY

Marijuana and other cannabinoids such as hashish (dried cannabis resin) exert their effects by binding to the cannabinoid receptors, of which two are currently known. Binding to the CB1 receptor, which is located primarily in the brain, appears to be responsible for the psychoactive effects of THC, whereas the CB_2 receptor may be associated with immune system responses.

CLINICAL MANIFESTATIONS

When marijuana is smoked, its psychoactive effects occur almost immediately, with peak intensity approximately 30 minutes later; effects tend to disappear within 3 hours. Oral administration of marijuana leads to a delayed onset of action, but the effects of the drug persist for a longer time. Because THC is highly soluble in lipids, it can be stored in fat depots of regular users for several weeks, sometimes longer, with resultant positive urine test results for THC. Physiologic effects of marijuana intoxication include increased heart rate and conjunctival injection. Psychological effects include a sense of euphoria and well-being, friendliness, increased appetite, a distorted sense of time, impaired short-term memory, and sometimes a feeling of having achieved special insights. Cannabis has the capacity to cause tolerance in regular users, and some regular heavy users experience withdrawal symptoms on cessation of use, including irritability, difficulty in sleeping, and anxiety.[7]

TREATMENT

The most common acute adverse event that occurs in marijuana smokers is a sense of acute panic, most common in inexperienced smokers, when the user's level of intoxication is greater than expected and the individual feels out of control. This can be best managed with reassurance that the effects will go away as the drug wears off. Recent evidence has shown that cannabis use, particularly during adolescence, may increase the likelihood for development of a psychotic disorder such as schizophrenia later in life.

Compared with alcohol, opioids, and stimulants, it has been relatively uncommon for people to seek treatment of cannabis use disorder itself. However, that situation has gradually changed in recent years, and an increasing number of people have sought treatment because of difficulty in stopping marijuana use. There are no medications approved by the FDA for the treatment of cannabis use disorder. Psychosocial approaches similar to the treatment of other substance use disorders are currently the treatment of choice.

Hallucinogens

Hallucinogens are a group of plant-based and synthetic drugs that lead to primarily visual perceptual alterations, such as illusions and hallucinations, along with an alteration in the experience of external stimuli; ordinary events can appear profound to people while they are under the influence of these agents. The most common hallucinogens are lysergic acid diethylamide (LSD), mescaline, and psilocybin. Methylene dioxymethamphetamine (MDMA), also known as ecstasy, has both mild stimulant and potentially hallucinogenic properties and is thus sometimes categorized with the hallucinogens and sometimes as a stimulant.

EPIDEMIOLOGY

Approximately 1 million people in the United States report having used a hallucinogen in the previous month; approximately 36 million people have used these drugs during their lifetime. LSD is the most commonly used hallucinogen, with 23 million lifetime users in the United States; approximately 60% of that number have used MDMA.

PATHOBIOLOGY

LSD is thought to exert its action through serotonin agonist activity, particularly at the 5-HT_{2A} receptor. Other neurotransmitters may be involved in hallucinogenic activity as well. Hallucinogens can produce tolerance in a matter of days, but they do not produce physical dependence.

CLINICAL MANIFESTATIONS

In addition to their effects on perception and behavior, hallucinogens can produce sympathomimetic effects such as tachycardia, increased blood pressure and body temperature, and pupillary dilation. Hyperreflexia and muscle weakness can also be seen. The most commonly seen medical consequence of hallucinogen use is hyperthermia, which can occur most commonly in users of MDMA.

The most common acute psychological adverse event, similar to marijuana, is a feeling of panic over the sense of loss of control that a person may feel as a result of intoxication; as is the case with marijuana, this is most likely to occur in inexperienced users. Some hallucinogen users will develop psychotic symptoms that fail to remit after the drug has worn off. Some hallucinogen use can also lead to longer-term perceptual difficulties. When these occur, a spontaneous return of very brief hallucinogen-induced symptoms long after the drug has worn off is known as a flashback. People who have perceptual difficulties that are much more pervasive may be said to have *hallucinogen persisting perception disorder*, which can at times be quite disabling.

TREATMENT

Symptomatic treatment is focused on the specific adverse medical and psychiatric sequelae described previously. If a psychotic episode that occurs after use of a hallucinogen persisted over time, it would be treated like any other psychotic disorder. There is no specific treatment for hallucinogen use disorder, and it is uncommon for people to seek treatment specifically because they want to stop using hallucinogens.

Phencyclidine

Phencyclidine (PCP) was originally developed as a human general anesthetic, but its use for that purpose was stopped in the 1960s because it frequently led to psychosis and hallucinations in the postoperative period. Approximately 120,000 individuals report that they used PCP during 2011. Low doses of PCP can lead to symptoms that resemble alcohol intoxication, with slurred speech, ataxia, and a subjective feeling sometimes described as "feeling dead." PCP intoxication typically is accompanied by increased muscle tone, hyperreflexia, nystagmus, and ataxia.

When it is taken in high doses, PCP can have serious medical and psychiatric consequences. High-dose users may experience psychosis, catatonia, and extremely violent behavior. Medical sequelae of PCP intoxication can include muscle rigidity, seizures, hyperthermia, coma, and occasionally death.

Anabolic-Androgenic Steroids

Anabolic-androgenic steroids differ from other drugs described in this chapter because the motivation for use is typically related to the drug's physical rather than behavioral effects. Anabolic-androgenic steroids such as testosterone and its synthetic analogues have traditionally been used primarily to enhance strength and thus athletic performance, although in recent years, an increasing number of people have used these drugs primarily in an attempt to improve their physical appearance. Anabolic-androgenic steroids can have a legitimate medical purpose; they have most commonly been used to treat testosterone deficiency in men and more recently have been used to treat wasting syndromes in patients with AIDS.

Abuse of anabolic-androgenic steroids can cause a number of medical and psychiatric problems, including hypertension, elevated low-density lipoprotein cholesterol, cardiomyopathy, hepatotoxicity, acne, feminization (gynecomastia and reduced testicular size) in men, and masculinization (hirsutism, reduction in breast tissue, deeper voice) in women. Behavioral effects include aggressiveness (sometimes leading to violence) and an increased prevalence of mood disorders. There is no specific treatment to help people abusing anabolic steroids to stop. Rather, behavioral treatment approaches that are commonly used to treat other substance use disorders should be employed with this population.

CONCLUSIONS AND FUTURE DIRECTIONS

The ever-changing epidemiology of drug abuse means that the next decade will likely present new challenges as new drugs of abuse become increasingly popular. Recent research has focused on development and testing of effective pharmacologic and behavioral treatments for substance use disorders. Screening for these disorders in general medical practice and combining office-based interventions with referrals to specialty substance use disorder treatment as indicated can lead to successful outcomes for many of these patients.

REVIEW QUESTIONS

1. Which of the following substances is NOT associated with withdrawal seizures?

A. Cocaine
B. Alprazolam
C. Butalbital
D. Alcohol
E. Chlordiazepoxide

Answer: A Cocaine causes a seizure upon intoxication, not withdrawal. Sedative-hypnotic agents cause withdrawal seizures.

2. Which of the following symptoms is seen as a result of opioid withdrawal?

A. Grand mal seizure
B. Miosis
C. Constipation
D. Tachycardia
E. Synesthesia

Answer: D Miosis and constipation occur with intoxication, seizures are not seen with opioid withdrawal, and synesthesia (seeing sounds, hearing colors) is seen in hallucinogen intoxication.

3. Which of the following symptoms does NOT count as a symptom of a substance use disorder?

A. Physical dependence in a patient taking opioids as prescribed for pain
B. Craving
C. Taking more than intended
D. Use despite family problems
E. Persistent desire to cut down on drug use

Answer: A Physical dependence and tolerance are not considered criteria for a substance use disorder if they occur as a result of appropriate medical care.

4. Which of the following is NOT an FDA-approved medication for treatment of opioid dependence?

A. Acamprosate
B. Oral naltrexone
C. Extended-release injectable naltrexone
D. Methadone
E. Sublingual buprenorphine

Answer: A Acamprosate is approved for the treatment of alcohol use disorders; the other medications are approved for the treatment of opioid dependence.

5. Other than marijuana, what type of drug is most widely abused?

A. Prescription drugs
B. Hallucinogens
C. Cocaine
D. Methamphetamine
E. Heroin

Answer: A Prescription drugs, especially opioids, are much more widely used nonmedically than the other drugs of abuse.

IMMUNOSUPPRESSING DRUGS INCLUDING CORTICOSTEROIDS

GRANT W. CANNON

IMMUNOSUPPRESSIVE DRUGS

The immune response is an essential host defense mechanism to control and fight infection. The ability to suppress immune reactions is a critical component in autoimmune disease treatment and transplantation management. During autoimmune diseases, the basic immune physiology is altered, and one or more components of this process do not function properly. Current challenges with the selection, dosing, monitoring, and development of immunosuppressing drugs involve identifying the component of the immune system to be altered by the immunosuppressive therapy while at the same time maintaining a competent immune response to fight infection and perform other important immunoregulatory functions. After organ transplantation, most patients have an immune response to reject the organ that has been implanted. Immunosuppression during transplantation management, in contrast to autoimmune disease, involves the suppression of normal immune reactions rather than an effort to alter a pathologic process. In this latter case, immunosuppressive therapy is directed to act on the altered immune system. Suppression of natural host immune responses affects the ability of these protective mechanisms to fight infection. The general principles for selecting immunosuppressive therapy in transplantation patients involve specific monitoring for organ rejection with subsequent selection of immunosuppressive therapy proportionate to the degree of rejection or for maintaining tolerance to the implanted organ. The selection of the most effective therapy requires an individualized treatment program. These decisions require an understanding of the underlying pathophysiologic process, prognosis, and potential adverse events for the agents selected.

This chapter describes the mechanism of action—including the components of the immune response affected by the therapy, indications, and adverse events associated with commonly used immunosuppressive agents in autoimmune diseases and transplantation. Whereas each of these agents has an individual discussion, these drugs are frequently used in combination as their complementary effects are employed. The understanding of the principles and adverse events associated with immunosuppressive therapy is important for all physicians as the use of these drugs becomes more widespread; however, their specific management and initiation, particularly in patients with organ transplantation and severe autoimmune diseases, should generally be limited to specialists with specific training in immunosuppressive therapies.

Corticosteroids

Corticosteroids are highly effective immunosuppressive agents and have had a major impact on the treatment of autoimmune diseases and the effort to avoid rejection of transplants. Historically,[1] the initial enthusiasm for the marked clinical benefit of corticosteroids in the treatment of rheumatoid arthritis was dampened by the significant adverse events that developed after prolonged use. As opposed to many adverse events that may develop as allergic and idiosyncratic reactions to medications, most adverse events with corticosteroid therapy are a direct consequence of the physiologic effects of the drug. This observation sparked a determined effort to understand the mechanisms of actions of corticosteroids at physiologic levels and therapeutic doses. The objectives of these investigations have been to develop modifications of the naturally occurring hormones to exploit the clinical benefits provided by corticosteroids while avoiding the associated adverse effects.

Mechanism of Action

Corticosteroids affect multiple physiologic functions at the molecular, cellular, and organ level. The final result of corticosteroid treatment represents the composite effects of the drug on these multiple functions, which vary with the particular agent, dose, route, and duration of treatment[2] (Table 35-1).

TABLE 35-1 CLASSIFICATION OF IMMUNOSUPPRESSIVE AGENTS

CORTICOSTEROIDS
Binding to cytosol glucocorticoid receptor: results in suppression of pro-inflammatory cytokines (genomic effects)
Inhibition of arachidonic acid release and binding to surface receptor (nongenomic effects)
Results of corticosteroid actions
Leukocyte numbers
Increase in circulating neutrophils
Decrease in circulating lymphocytes, monocytes, eosinophils, and basophils
Leukocyte function
Neutrophils: decrease in trafficking
Lymphocytes: decrease in cellular immune functions and immunoglobulin production
Cytokines
Decrease in pro-inflammatory cytokines: IL-1, IL-2, IL-6, and tumor necrosis factor-α
Increase in anti-inflammatory cytokines: IL-4, IL-10, and IL-13
Prostaglandins and leukotrienes: decreased production
PURINE PATHWAY INHIBITORS
Azathioprine: inhibition of DNA synthesis and purine synthesis
Mycophenolate mofetil: inhibition of purine synthesis
PYRIMIDINE PATHWAY INHIBITORS
Leflunomide: inhibits pyrimidine synthesis by inhibiting dihydroorotate dehydrogenase
IMMUNOPHILIN-BINDING AGENTS
Calcineurin inhibition
Cyclosporine: binds with cyclophilin to inhibit calcineurin, resulting in decreased T-cell activation
Tacrolimus: binds with FKBP12 to inhibit calcineurin, resulting in decreased T-cell activation
Mammalian target of rapamycin (mTOR) inhibition
Sirolimus: binds to FKBP12 to inhibit mTOR, resulting in decreased T-cell activation
ALKYLATING AGENTS
Cyclophosphamide: alkylation of nucleic acids with cytotoxic action

FKBP12 = 12-kD FK-binding protein; IL = interleukin.

Molecular Action

Genomic Effects

Corticosteroids are lipophilic and rapidly cross cell membranes into the cytosol, where they bind to the glucocorticoid receptor. The complex of glucocorticoid and its receptor then enters the nucleus and affects gene transcription by binding to glucocorticoid response elements. The complex may either stimulate or suppress gene transcription and subsequent protein production. This mechanism may have an impact on the function of 1% of all genes and suppresses the production of cytokines and other important inflammatory proteins. In addition to binding to glucocorticoid response elements, the glucocorticoid-glucocorticoid receptor complex also suppresses signal transduction pathways such as transcription factor activator protein-1 (AP-1), nuclear factor-κB (NF-κB), and nuclear factor of activator of T cells (NF-AT). Corticosteroids may also act to affect post-transcription and post-translation steps of protein synthesis. The anti-inflammatory actions of corticosteroids may be related to their action on the NF-κB and AP-1 pathways; the adverse events produced are related more to the activation or suppression of gene transcription. More recently, it has been recognized that corticosteroids can also regulate the mitochondrial genome. Glucocorticoid receptors are likewise present in mitochondria, and the mitochondrial genome contains glucocorticoid response elements.[3]

Nongenomic Effects

The genomic effects of corticosteroids require the diffusion of the drug into the cell, binding to the receptor, entry into the nucleus, and alteration of transcription. The ultimate effect on protein synthesis is not immediate, and it generally takes at least 30 minutes before any response is seen. The observation that some actions of corticosteroids are seen immediately has directed a search for nongenomic effects of corticosteroids. The glucocorticoid-glucocorticoid receptor complex can inhibit arachidonic acid release. In addition to the cytosol glucocorticoid receptor, membrane-bound receptors may be present that interact with cytoplasmic kinase–signaling molecules and G proteins and may mediate the rapid, nonclassic steroid effects and nongenomic functions.[2]

Systemic Effects

Impact on Leukocytes

Corticosteroids affect the activation, production, circulation, function, and survival of leukocytes. Whereas these impacts appear to be principally modulated by the genomic effects of corticosteroids on cytokines, corticosteroids also act on adhesion molecules and other mechanisms. The effects are on neutrophils, monocytes, macrophages, lymphocytes, eosinophils, and basophils. With corticosteroid therapy, neutrophils increase in the peripheral circulation (Chapter 167), primarily because of demargination, in contrast to a decrease in monocytes, lymphocytes, eosinophils, and basophils. Although the number of circulating neutrophils may increase, trafficking appears to be impaired. The impact on T cells is more pronounced than the effects on B cells, with the induction of apoptosis particularly in immature and activated T cells. Although function of B cells and neutrophils is not affected as strongly as that of T cells, high-dose prolonged use of corticosteroids can lead to suppression of antibody production.

Changes in Inflammatory Mediators

Corticosteroids result in a decrease in multiple pro-inflammatory cytokines and interleukins (ILs).[4] The cytokines affected include IL-1, IL-2, IL-6, and tumor necrosis factor-α, at the same time that there is an increase in anti-inflammatory cytokines—IL-4, IL-10, and IL-13. Corticosteroids have been associated with a reduction in the production of prostaglandins, leukotrienes, and other arachidonic acid metabolites, probably related to the reduced production of cyclooxygenase-2 and phospholipase A_2–related pro-inflammatory compounds (Chapter 37).

TREATMENT

Specific Issues with Corticosteroid Therapy

Multiple corticosteroid compounds and preparations are available. Many of the commonly employed compounds are listed in Table 35-2. These compounds have differences in potency, half-life, and sodium-retaining properties. More recently, delayed-release prednisone has been licensed for clinical use and may have a special role in the treatment of inflammatory conditions with circadian features.[5] In many conditions, the local administration of corticosteroids will provide clinical benefit without the systemic toxicity associated with oral therapy. Local therapies include topical, ophthalmic, inhaled, and local injection, such as soft tissue and intra-articular injections. Although the potential for adverse events is generally reduced with local therapy, local toxicities can develop, as can systemic effects if large doses of topical corticosteroids are used.

Whereas most conditions can be treated with local or oral corticosteroids, intravenous administration can provide pulse doses if desired. Intravenous therapy may also be used in situations in which the patient cannot take oral medication or the absorption of oral agents is impaired. Pulse therapy is generally administered in high intravenous doses that are often given as divided treatments during 3 to 5 days. High-dose pulse therapy has particularly been advocated in acute organ transplantation rejection, severe systemic lupus erythematosus (SLE), aggressive vasculitis, and other acute and severe autoimmune disorders. The use of high-dose pulse corticosteroid therapy has been associated with the development of sudden cardiac arrhythmias and sudden death. Many of the patients described have had serious concurrent diseases that could in part be responsible for electrolyte abnormalities and other associated morbidities that could contribute to these observations. Despite the confusion about this association, close monitoring of patients receiving high-dose pulse corticosteroid therapy is warranted.

Indications

Corticosteroids are employed in a large range of autoimmune disorders and transplantation procedures. A listing of each indication for which corticosteroids have been employed and proven effective is beyond the scope of this chapter, but indications range from multiple rheumatologic disorders to transplantation and many other inflammatory conditions. For example, the demonstration that inflammation plays a significant role in reactive airway disease has dramatically increased the use of systemic and inhaled corticosteroids in asthma and chronic obstructive pulmonary disorders. The challenge is to determine the appropriate dose, route, and duration of therapy with these disorders. For severe autoimmune disorders, high doses of corticosteroids are employed. In many cases, oral administration of prednisone, 60 to 80 mg/day as single or divided doses, can be employed. If patients cannot take oral

TABLE 35-2 GLUCOCORTICOID PREPARATIONS

	ANTI-INFLAMMATORY POTENCY	EQUIVALENT DOSE (mg)	SODIUM-RETAINING POTENCY	PLASMA HALF-LIFE (min)	BIOLOGIC HALF-LIFE (hr)
Hydrocortisone	1	20	2+	90	8-12
Cortisone	0.8	25	2+	30	8-12
Prednisone	4	5	1+	60	12-36
Prednisolone	4	5	1+	200	12-36
Methylprednisolone	5	4	0	180	12-36
Triamcinolone	5	4	0	300	12-36
Betamethasone	20-30	0.6	0	100-300	36-54
Dexamethasone	20-30	0.75	0	100-300	36-54

medication or high doses of corticosteroids are indicated, higher doses can be administered intravenously. Comparative data on the most appropriate doses and routes of administration are generally not available. Clinical judgment and empirical literature have formed the basis of these treatment regimens.

Adverse Effects

As noted previously, most adverse events associated with corticosteroid use are caused by the physiologic action of these drugs. Investigations are ongoing to determine whether separate mechanisms might be more associated with the therapeutic benefits whereas other pathways are more involved in the adverse events of corticosteroids. Currently available forms of corticosteroids do not selectively allow separation of the adverse events from the therapeutic effects. For example, the increase in infection associated with corticosteroids is the result of the impact of these drugs on leukocyte function and antibody production and is not an allergic reaction. The prevalence and severity of these adverse effects increase in proportion to the dose and duration of the therapy. The key to reducing adverse events with corticosteroids is to use the lowest needed dose and shortest possible duration for the required indication. Data also suggest that intermittent and every-other-day dosing may be associated with less toxicity than daily or divided daily doses.

Despite these limitations, corticosteroids are the only viable treatment option in many conditions, and efforts must be made to prevent, to detect development of, and to monitor for these adverse events. In most situations, education of the patient coupled with vigilant surveillance can detect these adverse events and often reduce their serious impact.

The following description of adverse events is not intended to be a comprehensive list of all reported adverse events associated with corticosteroids. The problems with infection, osteoporosis, metabolic abnormalities, and cardiovascular effects are highlighted because specific interventions can have an impact on these complications through proper education of the patient, monitoring, or prophylactic therapy.

Infections

Infections are increased in patients taking corticosteroids, particularly bacterial, fungal, and mycobacterial infections. The increased incidence and general severity of these infections are complicated by the anti-inflammatory actions of corticosteroids that can mask many of the cardinal signs of infection, such as fever, inflammation, and local discomfort. Patients taking corticosteroids should be alerted to the possibility of these "subclinical infections," and the provider must be vigilant in investigating signs and symptoms that may be less concerning in patients not taking corticosteroids. Management of infections in patients receiving corticosteroids requires close monitoring. Appropriate diagnostic procedures, antimicrobial therapy, and supportive measures are keys to successful management of infections in immunocompromised hosts. Patients with adrenal suppression may require "stress doses" of corticosteroids during the initial treatment of an infection. However, when possible, a reduction in corticosteroid dose may help restore a host immune response to the underlying infection, particularly with chronic infections.

Preventive measures to reduce infections include proper immunizations. If possible, for example, in a patient being evaluated for future transplantation, immunizations should be given before the immunosuppressive therapy. In many cases, a delay of immunosuppressive therapy is not possible to allow immunizations to be updated. However, in patients receiving chronic immunosuppressive therapy, routine immunizations should be offered when the disease is stable. Prophylactic antibiotics are generally not recommended to prevent infections in patients receiving corticosteroid therapy. However, two notable exceptions are the use of antituberculosis therapy in purified protein derivative–positive patients and trimethoprim-sulfamethoxazole therapy in patients receiving high-dose corticosteroid therapy for *Pneumocystis jirovecii* (previously named *Pneumocystis carinii*) prophylaxis.

Osteoporosis

Bone loss (Chapter 243) with corticosteroids affects multiple sites and has a greater impact on trabecular bone than on cortical bone. Common sites for involvement are the spine and femur, with associated fracture rates that may be as high as 20%, depending on the duration and dose of therapy. On initiation of long-term corticosteroid therapy, all patients should be evaluated for osteoporosis prophylactic therapy (Chapter 243). Unless it is contraindicated, patients should have adequate calcium and vitamin D through diet or supplements. In many patients, bisphosphonates will provide significant protection. Postmenopausal women should be evaluated for potential estrogen replacement therapy that may be helpful if benefits of therapy with corticosteroids are considered to outweigh the risks for cardiovascular disease and malignant disease. If osteoporosis develops in a patient receiving corticosteroids, efforts should be made to discontinue therapy or to reduce dose. Agents employed for treatment of osteoporosis should also be employed. Effective therapies include bisphosphonates, hormone replacement therapy, and anabolic agents such as parathyroid hormone preparations. These agents are generally used in association with calcium and vitamin D supplementation. An algorithm for prevention and treatment of glucocorticoid-induced osteoporosis is provided (Fig. 35-1).[6]

Metabolic Effects

The metabolic effects of corticosteroids may affect glucose metabolism, with results ranging from mild glucose intolerance to frank diabetes. Patients beginning corticosteroid therapy should be monitored for glucose intolerance and treated if significant hyperglycemia develops. The management of patients with existing diabetes is particularly challenging during corticosteroid therapy and requires close monitoring and adjustments of the diabetes management program. Other metabolic complications of corticosteroid treatment include weight gain with truncal obesity, electrolyte abnormalities including hypokalemia, and fluid retention.

Tapering Steroids

Exogenous corticosteroids will suppress the hypothalamic-pituitary-adrenal (HPA) axis. The likelihood of adrenal suppression increases with dose and duration of therapy. HPA axis suppression should be considered in patients receiving doses of 20 mg/day or more for 3 weeks or longer, although suppression can occur with lower doses. Formal evaluations can be performed to test the integrity of the HPA axis, but in most cases a scheduled taper of corticosteroid dose during several weeks will allow the return of HPA axis function without signs of adrenal insufficiency. The ideal rate for tapering corticosteroids has not been evaluated by clinical trials. The rate of reduction

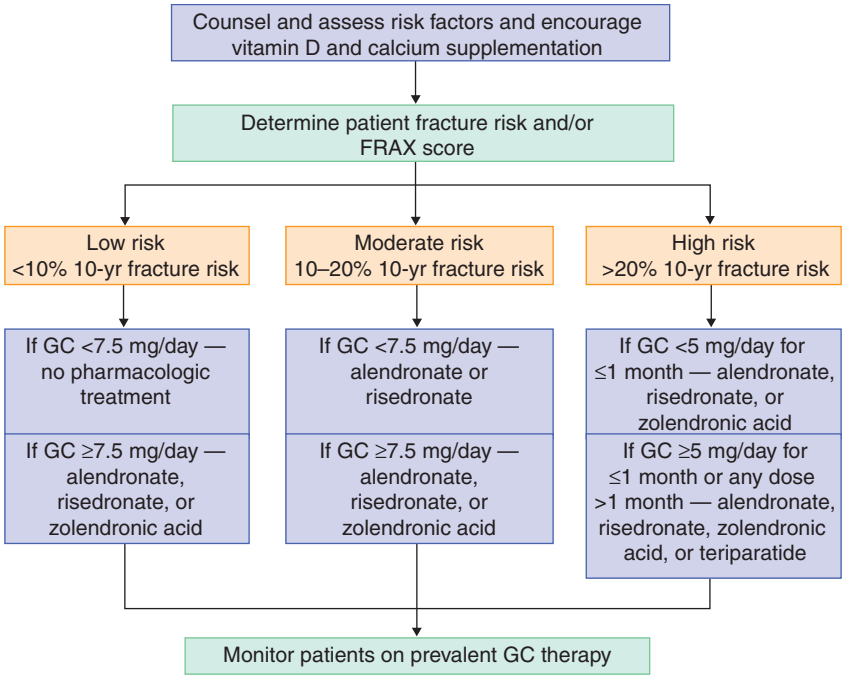

FIGURE 35-1. Algorithm for prevention of steroid-induced osteoporosis on initiation of glucocorticoid (GC) therapy. FRAX = World Health Organization Fracture Risk Assessment Tool. (Modified from American College of Rheumatology 2010 recommendations for the prevention and treatment of glucocorticoid-induced osteoporosis. *Arthritis Rheum.* 2010;62:1515-1526.)

in corticosteroid dose is often limited more by concerns over the potential relapses of disease activity than by the development of adrenal insufficiency. In general, if there is not a significant concern for a flare of the disease, a rapid reduction in dose to about 10 mg prednisone-equivalent per day is well tolerated. This dose replaces the normal physiologic production of cortisol. After this point, reductions in dose of 1 to 2.5 mg/day every 1 to 2 weeks will generally be well tolerated and may be accomplished by decreasing the dose of alternate-day treatment over 6 to 8 weeks. However, with acute medical illness, patients who have received corticosteroid doses in the past sufficient to cause HPA suppression should receive stress doses of steroids for a period of up to 1 year after the steroid treatment.

Cardiovascular Effects

Corticosteroids may induce or exacerbate cardiovascular risk factors, including hypertension, hyperlipidemia, and diabetes. Multiple mechanisms have been proposed for these effects, but the end result is that patients taking corticosteroids have an increased prevalence of atherosclerotic diseases and their associated complications. This problem is further complicated by the increased risk for cardiovascular disease in patients with inflammatory conditions, including rheumatoid arthritis and SLE, above that risk predicted by traditional risk factor assessment. These observations have emphasized the need to monitor corticosteroid-treated patients closely for cardiovascular risk factors with aggressive treatment of detected abnormalities.

Other Adverse Effects

Many other adverse events have been noted with corticosteroid therapy and are listed in Table 35-3. Osteonecrosis (avascular necrosis) is common during corticosteroid therapy and particularly involves the femoral head. Peptic ulcer disease is increased independently of concurrent nonsteroidal anti-inflammatory therapy. Cataracts and a variety of dermatologic abnormalities are more common. Muscle weakness or steroid myopathy, alteration of mood and behavior, and psychosis may develop. This broad spectrum of clinical complications requires the prescriber of corticosteroids to be aware of and alert to the development of these adverse events.

Purine Inhibition

Purines are critical components of nucleic acids and are particularly important in proliferating cells as part of cell growth and division. The inhibition of purines by competitive inhibitors (azathioprine and 6-mercaptopurine) or blocking critical enzymes (mycophenolate mofetil) in the purine pathway is an effective method of immunosuppression.

Azathioprine and 6-Mercaptopurine

Mechanism of Action

Azathioprine is an inactive compound that is metabolized to the active compound 6-mercaptopurine (6-MP). The exact mechanisms of action of 6-MP and its metabolites have not been fully established. At high doses, 6-MP may be incorporated into RNA and DNA, resulting in a cytotoxic effect; however, this effect is probably not the major action of the drug at the doses generally employed for immunosuppression. Most likely through feedback inhibition of de novo purine synthesis, 6-MP and its metabolites may reduce cell proliferation and thus produce immunosuppression. Genetically controlled differences in the activity of enzymes involved in the metabolism of 6-MP have been identified. The enzyme thiopurine *S*-methyltransferase is responsible for the metabolism of 6-MP to the metabolite methyl-6-MP. A rare homozygous (0.3%) and heterozygous (10%) defect in thiopurine *S*-methyltransferase is associated with increased toxicity, with severe hematologic toxicity in the homozygous patients.

The drug is metabolized eventually by xanthine oxidase. Because xanthine oxidase is inhibited by allopurinol, the concurrent use of allopurinol and azathioprine or 6-MP can result in a significant reduction in the metabolism of the active compounds and a significant increase in drug toxicity. For this reason, the combination of allopurinol and azathioprine should be avoided.

Indications

Azathioprine is approved by the U.S. Food and Drug Administration (FDA) for prevention of rejection of renal transplantation and treatment of rheumatoid arthritis. Clinical trials and reports have suggested that azathioprine also has efficacy during other types of organ transplantation and for autoimmune diseases. Azathioprine has been particularly effective at providing an adjunct to corticosteroid therapy, allowing a reduction in corticosteroid dose and avoiding the associated adverse events.

Adverse Effects

Serious infections are reported during treatment with azathioprine, similar to those seen with other immunosuppressive drugs. Opportunistic infections are a particular concern. Hematologic abnormalities include leukopenia, thrombocytopenia, and anemia. A complete blood count (CBC) is recommended on a regular basis, with increased frequency at the initiation of therapy. Current guidelines recommend a CBC weekly during the first month of azathioprine therapy, twice weekly during the second and third months, and monthly thereafter. Genotyping of the enzyme thiopurine *S*-methyltransferase may identify subjects with the highest risk for

TABLE 35-3 MAJOR ADVERSE EVENTS ASSOCIATED WITH IMMUNOSUPPRESSIVE THERAPIES*

CORTICOSTEROIDS
Serious and opportunistic infections
Osteoporosis
Metabolic disorders: hyperglycemia, adrenal suppression, hyperlipidemia, electrolyte abnormalities, fluid retention, hypertension, truncal obesity
Cardiovascular
Miscellaneous: osteonecrosis, peptic ulcer disease, cataracts, dermatologic abnormalities, steroid myopathy, psychosis, growth retardation, altered mood and behavior
AZATHIOPRINE
Serious and opportunistic infections
Hematologic abnormalities: leukopenia, thrombocytopenia, anemia
Gastrointestinal: nausea, vomiting, rare hepatitis
Reproductive: pregnancy class D
Miscellaneous: pancreatitis, interstitial pneumonitis, rashes
MYCOPHENOLATE MOFETIL
Serious and opportunistic infections
Leukopenia
Gastrointestinal: diarrhea, nausea, dyspepsia, elevated transaminases
Reproductive: pregnancy class C
CYCLOSPORINE
Serious and opportunistic infections
Renal disease and hypertension
Potential for increased malignant neoplasms
Reproductive: pregnancy class C
Miscellaneous: hirsutism, gingival hyperplasia, hyperuricemia, electrolyte abnormalities
TACROLIMUS
Serious and opportunistic infections
Renal disease and hypertension, perhaps lower than with cyclosporine
Potential for increased malignant neoplasms
Post-transplantation diabetes mellitus
Neurotoxicity: tremor, headaches, motor function abnormalities, mental status alteration, sensory changes
Reproductive: pregnancy class C
Miscellaneous: hirsutism, gingival hyperplasia, myocardial hypertrophy
SIROLIMUS
Serious and opportunistic infections
Renal disease and hypertension
Potential for increased malignant neoplasms
Reproductive: pregnancy class C
Miscellaneous: hyperlipidemia, pneumonitis, interstitial lung disease
CYCLOPHOSPHAMIDE
Serious and opportunistic infections
Increased incidence of malignant neoplasms
Hematologic toxicity: leukopenia, thrombocytopenia, anemia
Reproductive: pregnancy class D, premature ovarian failure, oligospermia, fetal abnormalities
Urologic: hemorrhagic cystitis, bladder cancer
Miscellaneous: nausea, vomiting, diarrhea, pulmonary fibrosis

*This list highlights the most serious and common adverse events but does not include all reported adverse events with these agents.

hematologic toxicity but does not substitute for monitoring of the CBC. Gastrointestinal toxicity is usually minor, but patients may have significant symptomatic complaints of nausea, vomiting, diarrhea, and epigastric pain that are often self-limited and reversible. A severe hepatic toxicity has been rarely reported, leading to a recommendation for regular monitoring of serum transaminases, alkaline phosphatase, and bilirubin, particularly during the first 6 months of therapy. Rare complications of azathioprine treatment include fever, arthralgia, rash, pancreatitis, and interstitial pneumonitis.

Azathioprine use in pregnancy is classified category D and has been associated with fetal abnormalities in animals. The use of azathioprine should be avoided, if possible, in pregnant women and nursing mothers, although patients with organ transplantation and autoimmune disease have had successful pregnancies while receiving azathioprine.

The association of azathioprine treatment with the development of malignant neoplasms has been controversial. In most clinical situations, azathioprine is used in conditions and in combination or temporal sequence with other drugs that are associated with the development of malignant diseases. For example, patients with systemic vasculitis or SLE may initially be treated with cyclophosphamide and then are often subsequently treated with azathioprine. An increase in malignant neoplasms in this population could be related to the concurrent azathioprine treatment, but the prior cyclophosphamide therapy may be a higher risk factor. In addition, patients with solid organ transplantation, another circumstance in which azathioprine is frequently employed, appear to have a higher rate of malignant neoplasms separate from the use of immunosuppressive drugs. Extensive efforts to identify an independent increased risk for malignant neoplasms with azathioprine have not produced consistent results. These results suggest that the risk for malignant transformation with azathioprine is very low if this risk exists at all.

Azathioprine is an important and effective therapy in organ transplantation and autoimmune disease. Often this drug is used in combination with other agents and as a corticosteroid-sparing drug. Surveillance for infection and monitoring for hematologic toxicity are important. Concurrent treatment with allopurinol should be avoided to prevent serious toxicity from an interaction of the two drugs.

Mycophenolate Mofetil

Mechanism of Action

Mycophenolate mofetil is a prodrug that is converted in vivo to the active compound mycophenolic acid. Mycophenolic acid acts through inhibition of the enzyme inosine monophosphate dehydrogenase, resulting in an increase in 6-thionosinic acid that is normally metabolized by this enzyme. The accumulation of 6-thionosinic acid acts through a negative feedback loop to suppress the de novo synthesis of purines and associated DNA production. Although it is not a cytotoxic agent, the actions of mycophenolic acid are most pronounced on proliferating cells, such as lymphocytes, to reduce cell division and associated functions of these critical cells in the immune response.

Indications

Mycophenolate mofetil is approved by the FDA for the prevention of allograft rejection in renal, hepatic, and cardiac transplantation. In addition to these approved indications, mycophenolate mofetil has been evaluated in SLE, for which its principal use has been in patients with lupus nephritis, although the drug has been used for other manifestations. In the treatment of SLE, it can be used successfully in patients who no longer respond to azathioprine[7] and can be used as initial and maintenance therapy for lupus nephritis. Limited use has been reported in other autoimmune diseases such as rheumatoid arthritis, vasculitis, and polymyositis.

Adverse Effects and Monitoring

Common adverse events with mycophenolate mofetil include hematologic and gastrointestinal complications. Leukopenia is reported in 20 to 35% of patients receiving this drug for organ transplantation; however, severe neutropenia is seen in only 2 to 3% of subjects. Patients receiving mycophenolate mofetil have a higher susceptibility to infections, similar to that seen with other immunosuppressive agents, including opportunistic infections. Diarrhea, nausea, and dyspepsia are frequent. Abnormalities of liver enzymes are commonly noted and appear to be dose dependent. Rare complications include pulmonary fibrosis and malignant neoplasms. Mycophenolate mofetil is classified as category C by the FDA for use in pregnant women. Although the agent should be avoided in patients who are pregnant or not practicing adequate contraception, this drug appears to have less impact on the reproductive system than does cyclophosphamide. Patients with SLE who are concerned about a potential severe impact of cyclophosphamide on reproductive organs might elect to use mycophenolate mofetil instead.

Monitoring of patients receiving mycophenolate mofetil should include a monthly CBC and hepatic enzyme activities. Clinical monitoring for gastrointestinal and infectious complications should be conducted during regular clinical follow-up.

Mycophenolate mofetil is an important and effective agent in the management of transplantation patients. Ongoing work is studying the role of this drug in other autoimmune diseases. It is hoped that mycophenolate mofetil can provide effective therapy for rheumatic and autoimmune disorders with less toxicity than is seen with currently available agents, with a particular potential for use in lupus nephritis.

Immunophilin-Binding Agents

The development of immunophilin inhibitors has significantly advanced organ transplantation.[8] Each of these drugs—cyclosporine, tacrolimus (also known as FK506), and sirolimus (also known as rapamycin)—has significant

immunosuppressive activity on T-cell-mediated functions. Whereas the mechanisms of action for each drug differ, they all have the common action of binding to a cytosolic protein. This binding results in a decrease in T-cell cytokine production and T-cell proliferation. These separate sites of action allow the use of these agents in combination in transplantation management. In addition, the differences in action and specific binding for each drug have resulted in unique adverse events profiles.

Cyclosporine

Mechanism of Action

Cyclosporine acts by binding to the cytosolic protein cyclophilin to form a cyclosporine-cyclophilin complex. The cyclosporine-cyclophilin complex inhibits the enzyme calcineurin. Calcineurin is an enzyme involved in multiple T-cell functions and is of particular importance in enhancing the transcription of genes for pro-inflammatory cytokines. The use of cyclosporine inhibits the production of IL-2 with a resulting decrease in T-cell activation. Cyclosporine also inhibits the production of other cytokines, including IL-3, IL-4, granulocyte-macrophage colony-simulating factor, tumor necrosis factor-α, and interferon-α. The overall impact of these actions is to reduce immune function and inflammation.

Indications

The use of cyclosporine and other calcineurin inhibitors has revolutionized solid organ transplantation. The specific FDA-approved indications include renal, liver, and heart transplantation. Most often the drug is used in conjunction with other immunosuppressive agents including corticosteroids and azathioprine. The critical clinical challenge is to balance the potent immunosuppressive effects of the drug against the adverse events produced by this agent, with particular attention to avoidance of infectious complications and monitoring for hypertension and renal toxicity. Because of these critical issues, prescribing information specifically limits this agent to physicians experienced with the use of immunosuppressive agents.

Oral cyclosporine is also approved for the treatment of rheumatoid arthritis as a disease-modifying antirheumatic drug (DMARD), either alone or in combination with methotrexate. Although it is effective in the treatment of rheumatoid arthritis and other rheumatic diseases, cyclosporine does not provide a substantially greater efficacy than the other DMARDs. Cyclosporine is also approved for the treatment of psoriasis. Because of the significant adverse event profile, cyclosporine is generally reserved for patients with autoimmune diseases whose therapy with more traditional and less toxic agents has failed.

Topical cyclosporine is effective and approved for treatment to increase tear production presumed to be suppressed secondary to inflammation in patients with keratoconjunctivitis sicca syndrome (Chapter 423). The topical treatment is associated with a much lower frequency of adverse drug events than is systemic cyclosporine therapy.

Adverse Effects

Close monitoring is required during cyclosporine therapy. Blood levels can be measured, which is useful in ensuring that the drug remains within a therapeutic range and below levels associated with increased toxicity. Because of multiple potential drug interactions that can both raise and lower cyclosporine levels, as well as food interactions, particularly increased levels with grapefruit and grapefruit juices, patients should be constantly monitored and blood levels obtained when indicated. These evaluations should ensure that when medical therapy is added, changed, or deleted, these adjustments will not have an impact on the effects of the cyclosporine, with its associated therapeutic and toxicity issues.

Infection

All infections have an increased potential for developing in patients receiving cyclosporine and other calcineurin inhibitors as with other immunosuppressive agents. Opportunistic infections associated with impaired cell-mediated immunity are particularly increased.

Renal Disease and Hypertension

Renal disease and hypertension are common adverse events during cyclosporine therapy and are increased in prevalence with increases in dose and duration of therapy. Close monitoring of blood pressure and serum creatinine concentration is critical during treatment with cyclosporine. In many cases, these conditions are reversible if they are detected early and appropriate dose adjustments are implemented. In many patients, a mild increase in serum creatinine concentration may be tolerated if the level remains stable. Whereas renal abnormalities and hypertension are commonly identified during treatment of patients with cyclosporine, most patients will not require discontinuation of the drug if adjustments in dose or other interventions are undertaken to avoid these complications.

Malignant Neoplasia

Malignant neoplasms, particularly lymphomas, have been noted to be more common in patients receiving solid organ transplantation with associated immunosuppressive therapy. However, the exact cause of these malignant neoplasms has not been determined. In vitro mutagenesis assays with cyclosporine have been negative. In vivo animal studies have yielded equivocal results, with some data suggesting a possible increased rate of malignant neoplasms in rats and mice.

Issues with Reproduction

Cyclosporine is a pregnancy class C drug. Data in animals have demonstrated toxicity to both the embryo and fetus. Patients should practice effective contraception while receiving this drug. Data from pregnant transplant patients are difficult to interpret because cyclosporine is generally not the only medical therapy received by these women and the impact of the disease associated with the organ transplantation is at times difficult to separate from the impact of therapy. Despite these limitations, normal pregnancies and early childhood development have been reported in many women receiving cyclosporine. Premature birth and low birth weight are more common in women receiving cyclosporine. Therefore, although the use of cyclosporine during pregnancy and breast-feeding should be avoided if at all possible, in patients who become pregnant, an assessment should determine whether the immunosuppressive therapy should be continued. In some cases, the risk for organ rejection with discontinuation of cyclosporine therapy may exceed the risk for exposure to the fetus during pregnancy.

Other Adverse Effects

Cyclosporine has also been associated with the development of hirsutism, gingival hyperplasia, hyperuricemia, and electrolyte abnormalities.

Tacrolimus

Mechanism of Action

Whereas cyclosporine binds to cyclophilin, tacrolimus binds to a different protein, the 12-kD FK-binding protein (FKBP12). The binding of FKBP12 and tacrolimus forms a complex that inhibits calcineurin in a fashion similar to cyclosporine. Through this mechanism, tacrolimus has similar inhibitory effects on T-cell function and cytokine production.

Indications

Tacrolimus is approved for the prophylactic treatment of organ rejection after kidney and liver transplantation. The efficacy and safety in rheumatoid arthritis is limited but encouraging. Experience with this agent is less extensive than the experience with cyclosporine.

Adverse Effects

The major adverse events with tacrolimus are similar to those of cyclosporine and include increased susceptibility to infection, renal disease, and hypertension. An increase in malignant neoplasia is also reported with a pattern similar to that reported in patients receiving cyclosporine.

Whereas many adverse events with tacrolimus are similar to those of other calcineurin inhibitors, some specific complications have been reported, including the development of post-transplantation diabetes mellitus. This adverse event was seen in 20% of subjects in phase III clinical trials of tacrolimus with an onset generally within the first 3 months of therapy. In many patients, post-transplantation diabetes mellitus will resolve after the drug is discontinued. Neurotoxicity is also reported, including tremor, headache, motor function abnormalities, mental status alterations, and sensory changes. Myocardial hypertrophy has been reported. Tacrolimus, like cyclosporine, is pregnancy class C. Patients receiving this drug should practice effective contraception.

Sirolimus

Mechanism of Action

Sirolimus (or rapamycin) in not a calcineurin inhibitor but has many actions and mechanisms similar to calcineurin inhibitors. The mechanism of action of sirolimus involves binding to FKBP12, the binding protein for tacrolimus, but the effect of this binding is different. Instead of acting on calcineurin, the sirolimus-FKBP12 complex binds to another protein, the mammalian target

of rapamycin (mTOR), which is a key regulatory kinase. The inhibition of mTOR results in significant immunosuppression by decreasing T-cell proliferation and the progression from G_1 phase to S phase in the cell cycle. Because sirolimus works through a mechanism different from the mechanism of action for cyclosporine, the two drugs have been studied in combination. In renal transplantation patients, the use of these two agents in combination has a greater immunosuppressive effect than that of cyclosporine alone.

Indications

Sirolimus is approved for the prophylaxis of organ rejection in renal transplantation in combination with cyclosporine and corticosteroids for patients older than 12 years. Data with the use of sirolimus in other populations, including subjects with autoimmune diseases, are limited and generally are derived only from animal models.

Adverse Effects

The adverse event profile for infection and malignant neoplasms with sirolimus is similar to that with calcineurin inhibitors. Renal disease with cyclosporine and sirolimus in combination has been reported more frequently than in patients receiving cyclosporine alone. Adverse reactions specific for sirolimus include hyperlipidemia, interstitial lung disease, and the syndrome of calcineurin-induced hemolytic-uremic syndrome, thrombotic thrombocytopenic purpura, and thrombotic microangiopathy.

Alkylating Agents

Alkylating agents are an important component of immunosuppressive therapy in autoimmune diseases. The use of these agents is limited by their associated toxicity, particularly the potential for development of malignant neoplasia, reproductive toxicity, and increased incidence of infection. Patients considered candidates for alkylating therapy should be fully informed of the potential risks and benefits of these drugs and concur with the decision for their use. Regular monitoring of blood counts and urinalysis are important in observing patients receiving these drugs.

Cyclophosphamide

Cyclophosphamide has been used primarily as a cytotoxic drug for the treatment of malignant neoplasms; it is currently approved for this indication as well as for biopsy-proven minimal change nephrotic disease in children. Several severe autoimmune diseases have also been shown to be responsive to cyclophosphamide, often given in conjunction with initial high-dose corticosteroid therapy. Because of the significant toxicities associated with these drugs, a benefit-to-risk assessment and discussion should be undertaken with each patient as cyclophosphamide use is being considered. In most cases, the diseases warranting cyclophosphamide therapy will be life-threatening conditions with poor prognosis to justify the potential severe toxicity of this agent.

Mechanism of Action

Cyclophosphamide is an inactive compound that can be administered either orally or intravenously and is metabolized to the active drug by the cytochrome P-450 mixed function oxidase system. This process produces the active compounds phosphoramide mustard and the toxic metabolite acrolein. The cytotoxic effect of this drug results from the alkylation of various cellular constituents, especially nucleic acids. Changes in immune function with cyclophosphamide include depletion of lymphoid tissues, with decreases in both B and T cells, suppression of cellular immune function, and decreased antibody production.

Indications

Treatment of lupus nephritis and severe systemic vasculitis is the most well studied and common use of cyclophosphamide in the rheumatic diseases. Controlled clinical trials have demonstrated improved outcomes in these conditions, particularly with reduced progression to end-stage renal disease in patients with SLE and improved survival with systemic vasculitis such as granulomatosis with polyangiitis (GPA, formerly known as Wegener granulomatosis) and other forms of antineutrophil cytoplasmic autoantibody-associated vasculitis (AAV). However, there has been an increase use of rituximab (Chapter 36) in the treatment of AAV in place of cyclophosphamide with similar clinical benefit and less adverse events.[A2] The evaluation of cyclophosphamide in patients with SLE has demonstrated the benefit of intermittent, usually monthly, intravenous pulse therapy as a method to avoid some of the most severe toxic side effects while maintaining therapeutic efficacy. However, pulse intravenous cyclophosphamide has not been found to be as effective as continuous oral cyclophosphamide in all conditions, particularly GPA. Other conditions, such as polyarteritis nodosa, Takayasu arteritis, and Churg-Strauss syndrome, have been reported to benefit from cyclophosphamide; however, the low prevalence of these diseases has prohibited the conduct of controlled clinical trials to prove efficacy. Cyclophosphamide has also been demonstrated to be effective in the treatment of patients with rheumatoid arthritis, but it is generally not used in this condition because of the associated toxicity and availability of other effective agents. Although the use of cyclophosphamide has been a tremendous advance in the treatment of these life-threatening diseases, the use of less toxic medications, such as rituximab and mycophenolate mofetil, is under investigation to determine their relative clinical efficacy.

Adverse Effects

Before the initiation of cyclophosphamide therapy, a frank discussion with the patient about potential serious and even life-threatening adverse events should be undertaken and documented.

Malignant Neoplasia

Malignant neoplasms may develop in patients receiving cyclophosphamide for the treatment of both malignant and nonmalignant diseases. The risk for malignant change appears to increase with the duration and dose of cyclophosphamide. The most common malignant neoplasms are bladder, myeloproliferative, and lymphoproliferative disorders. The use of intravenous pulse cyclophosphamide may reduce but not eliminate the risk for bladder cancer. These malignant neoplasms may develop years after the discontinuation of the drug.

Reproductive Issues

Cyclophosphamide can be teratogenic, affect female reproduction, and reduce male fertility. Cyclophosphamide is pregnancy category D and should not be used in pregnant women unless life-threatening disease is present that warrants this treatment. Whereas successful pregnancies have been reported in patients receiving cyclophosphamide during pregnancy, fetal abnormalities are well documented secondary to chromosome damage in patients receiving cyclophosphamide. The use of cyclophosphamide in premenopausal women can induce premature ovarian failure. The use of gonadotropin-releasing hormone analogues during intravenous pulse cyclophosphamide therapy may reduce premature ovarian failure in patients with SLE; however, the risk of this complication is still present. In males, temporary and permanent decrease in sperm count may occur with cyclophosphamide. Because the recovery of fertility after cyclophosphamide is variable, sperm banking should be considered before therapy is begun.

Other Adverse Effects

As with other immunosuppressive agents, infections are more frequent and potentially more serious in patients receiving cyclophosphamide. Opportunistic infections are more likely to be seen in these subjects. Hematologic abnormalities can involve all cell lines. The CBC should be monitored regularly and cyclophosphamide discontinued or the dose reduced when cytopenias develop. Cyclophosphamide treatment may be complicated by hemorrhagic cystitis and bladder cancer, which are probably related to the toxic metabolite acrolein. Efforts to reduce the potential for hemorrhagic cystitis and bladder malignant neoplasms include the use of intravenous pulse therapy, hydration, frequent voiding, and treatment with agents containing sulfhydryl groups to scavenge acrolein. Regular urinalysis for blood is indicated to monitor for bladder toxicity. Patients may develop severe nausea, vomiting, and diarrhea with cyclophosphamide therapy.

Chlorambucil

Chlorambucil has not been evaluated as extensively as cyclophosphamide, but this agent appears to have properties and an adverse event profile similar to those of cyclophosphamide. Like cyclophosphamide, chlorambucil is associated with the development of malignant neoplasms and should be avoided during pregnancy.

Miscellaneous Agents

Although principally prescribed for other indications, methotrexate and leflunomide have been evaluated and used for their potential immunosuppressive effects. Leflunomide blocks the enzyme dihydroorotate dehydrogenase, resulting in an inhibition of pyrimidine synthesis and a reduction in

T-cell activation. Methotrexate has multiple mechanisms of action, but its major effect in autoimmune diseases is mediated by inhibition of the enzyme aminoimidazole-4-carboxamide ribonucleotide transformylase. This inhibition affects purine synthesis, increasing the intracellular concentration of aminoimidazole-4-carboxamide ribonucleotide, which stimulates the release of adenosine, a potent anti-inflammatory compound. Methotrexate has principally been advocated for its corticosteroid-sparing effects. Both methotrexate and leflunomide are effective DMARDs in the treatment of rheumatoid arthritis and are discussed in other chapters.

BIOLOGIC AGENTS AND SIGNALING INHIBITORS

CEM GABAY

Biologic agents are a new class of therapeutic agents that target different mediators involved in the pathogenesis of human diseases. The development of these therapies has markedly improved the management of many diseases. In addition, their use has greatly increased our understanding regarding the pathophysiology of these diseases. One of the most compelling examples is the efficacy of tumor necrosis factor (TNF)-α inhibitors in rheumatoid arthritis and in inflammatory bowel diseases. In addition, new drugs targeting specifically intracellular enzymatic signaling pathways (kinases) have been developed. Most of these signaling inhibitors have been developed for the treatment of cancer. Recently, a kinase inhibitor was approved for the treatment of rheumatoid arthritis.

The United States Adopted Names Council has established a common classification of these different therapies (Table 36-1). The pharmaceutical company usually gives the prefix of the name, and the suffix defines whether this is a monoclonal antibody (mab), a soluble receptor (cept), or a kinase inhibitor (inib). Monoclonal antibodies, by far the largest group of biologic agents today, include also in their name the type of target (immune system, cancer, cardiovascular, system, and bone) as well as their origin (chimeric, humanized, and human).

TABLE 36-1 NOMENCLATURE OF MONOCLONAL ANTIBODIES

TARGET	ABBREVIATION	EXAMPLE
Immunology	li/l	ada**li**mumab
Cardiovascular	ci/c	beva**ci**zumab
Bone	os/s	den**os**umab
Interleukin	ki/k	cana**ki**numab
Miscellaneous tumors	tu/t	ofa**tu**mumab
SOURCE		
Chimeric	xi	ritu**xi**mab
Humanized	zu	trastu**zu**mab
Human	u	golim**u**mab

From the United States Adopted Names Council website (www.ama-assn.org).

To make mouse- or other animal-derived monoclonal antibodies less immunogenic, chemical and genetic engineering methods can replace two thirds of the mouse antibody with human antibody, creating "chimeric" monoclonal antibodies, or can replace 90 to 95% with human antibody to create "humanized" monoclonal antibodies. Chimeric and humanized monoclonal antibodies, being less immunogenic, elicit the production of less neutralizing human antimouse antibodies in the recipient present.

All biologic agents are large molecules that are administered by intravenous or subcutaneous routes, whereas kinase inhibitors are small chemicals that are prescribed as oral drugs. For safety reasons, combination of biologic agents or kinase inhibitors is not recommended. Rather than providing an exhaustive review of all tested approaches, this chapter aims to review the currently approved treatments.

TUMOR NECROSIS FACTOR-α INHIBITORS

The cytokine TNF-α binds to two different receptors, TNF-R55 and TNF-R75, and exerts important functions in the control of host responses against infections. However, uncontrolled TNF-α production may lead to chronic inflammation and subsequent tissue damage.

Types of Tumor Necrosis Factor-α Inhibitors

Different agents have been developed to inhibit the biologic activity of TNF-α, including monoclonal antibodies and soluble receptors. Monoclonal antibodies include infliximab (Remicade), adalimumab (Humira), and golimumab (Simponi). Infliximab is a chimeric antibody, whereas the two others are fully human antibodies. Certolizumab-pegol (Cimzia) is a pegylated humanized anti-TNF-α antibody Fab′ fragment. Etanercept (Enbrel) is a fusion protein that contains the extracellular portion of TNF-R75 coupled to the Fc domain of human immunoglobulin G1 (IgG1). All these agents bind to TNF-α and block its biologic activity. Etanercept binds also to lymphotoxin-α (previously termed TNF-β). Infliximab has been shown to exert cytotoxic effects on macrophages and T lymphocytes expressing TNF-α on their surface.

Indications

TNF-α antagonists are approved for the treatment of rheumatoid arthritis (Chapter 264). They exert marked anti-inflammatory effects and prevent the progression of structural joint damage. TNF-α inhibitors are efficacious in early rheumatoid arthritis and in long-standing disease refractory to conventional disease-modifying antirheumatic drugs (DMARDs) such as methotrexate. TNF-α inhibitors are more efficacious when administered in combination with methotrexate than alone. TNF-α inhibitors are also approved for the treatment of ankylosing spondylitis refractory to nonsteroidal anti-inflammatory drugs and psoriatic arthritis refractory to DMARDs (Chapter 265). Anti-TNF-α antibodies, but not etanercept, have proven efficacy in severe Crohn disease (Chapter 141) by reducing the disease activity score, inducing closure of draining fistulas, and allowing a decrease in the dose of chronic glucocorticoid medication. Infliximab, adalimumab, and golimumab are approved for the treatment of ulcerative colitis refractory to conventional therapy. Infliximab, adalimumab, and etanercept are also approved for the treatment of chronic plaque psoriasis (Chapter 438) refractory to phototherapy or systemic therapy.

Adverse Effects

TNF-α inhibitors can be associated with allergic reactions. Postmarketing data have shown that TNF- α inhibitors are associated with an increased risk for infections, including all types of bacterial and opportunistic infections. In particular, the use of TNF-α inhibitors has been associated with an increased risk for reactivation of latent tuberculosis. The results of cohort studies do not support an overall increased risk for cancer. Rare cases of demyelinating disorders, lupus-like manifestations, and cytopenia have been reported.

INTERLEUKIN-1 INHIBITORS

IL-1 (both IL-1α and IL-1β) binds to IL-1 receptors (type I IL-1R and IL-1R accessory protein) to induce a vast array of inflammatory signals. IL-1 receptor antagonist (IL-1Ra) competitively inhibits the interaction of IL-1 with its receptors.[1]

Types of Interleukin-1 Inhibitors

Anakinra (Kineret), recombinant human IL-1Ra, was the first IL-1 inhibitor used in clinical trials. Rilonacept (Arcalyst) is a fusion protein including the

IL-1 binding motifs of IL-1 receptors coupled to the Fc domain of human IgG1. Canakinumab (Ilaris) is a fully human monoclonal antibody against IL-1β.

Indications

Anakinra is approved for the treatment of rheumatoid arthritis refractory to conventional DMARDs but exhibits relatively modest efficacy. Anakinra, canakinumab, and rilonacept are approved for the treatment of cryopyrin-associated periodic syndromes, a set of hereditary systemic autoinflammatory diseases associated with *NLRP3* gene (encoding for cryopyrin) mutations (Chapter 261) and characterized by enhanced IL-1β release. Canakinumab is approved for the treatment of systemic-onset juvenile idiopathic arthritis in children aged 2 years and older. Anakinra is also effective in adult-onset Still disease and other autoinflammatory conditions. Clinical trials have reported encouraging results with IL-1 antagonists in crystal-induced arthritis such as gout and chondrocalcinosis. Promising results have also been reported from the use of gevokizumab, another fully human anti-IL-1β monoclonal antibody in Behçet uveitis.

Adverse Effects

Anakinra, canakinumab, and rilonacept have frequently been associated with injection site reactions and upper airway infections. A modest increase in serious infections has been reported with the three IL-1 antagonists. The combination of anakinra and etanercept (and probably also other TNF-α antagonists) increases the risk for infections and is not recommended.

INTERLEUKIN-6 INHIBITORS

IL-6 is a pro-inflammatory cytokine that binds to a heterodimeric receptor, including IL-6Rα and gp130. Tocilizumab (Actemra) is a humanized monoclonal antibody against IL-6Rα that inhibits its interaction with IL-6.

Indications

Tocilizumab is approved for the treatment of rheumatoid arthritis refractory to conventional DMARDs and TNF-α antagonists.[2] In clinical trials, tocilizumab prevented the progression of radiographic damage. Tocilizumab in monotherapy seems as effective as in combination with methotrexate and is superior to adalimumab (TNF-α inhibitor) in monotherapy. Tocilizumab is also approved for the treatment of systemic-onset juvenile idiopathic arthritis and polyarticular juvenile idiopathic arthritis in patients aged 2 years and older. In Japan, tocilizumab is approved for the management of Castelman disease. Tocilizumab is also effective for adult-onset Still disease. Clinical trials are in progress in other inflammatory rheumatic diseases. In addition, clinical trials examining the efficacy and safety of other monoclonal antibodies against IL-6R (sarilumab) or IL-6 (sirukumab, clazakizumab) in rheumatoid arthritis are in progress.[3]

Adverse Effects

Tocilizumab has been associated with an increased risk for serious infections. A transient increase in transaminase levels has been reported. Hypercholesterolemia and cytopenia may appear in some patients.

ANTIBODY AGAINST INTERLEUKIN-12 AND INTERLEUKIN-23

IL-12 and IL-23 are heterodimeric cytokines, including a common p40 subunit and a specific subunit—p35 for IL-12 and p19 for IL-23. IL-23 participates in the differentiation of T_H17 cells that produce IL-17. Experimental findings indicated that IL-23 and IL-17 are critical for the development of autoimmune pathologies. Ustekinumab (Stelara) is a human monoclonal antibody against p40 that targets both IL-12 and IL-23 and blocks their biologic activities.

Indications

Ustekinumab is approved for the treatment of psoriasis patients who have had prior exposure to phototherapy or use of other systemic therapies. In clinical trials, ustekinumab was associated with successful treatment of Crohn disease. In addition, ustekinumab alone or in combination with methotrexate is also approved for the treatment of active psoriatic arthritis. Anti-IL-17 and anti-IL-17R antibodies are in clinical trials for the treatment of psoriasis, psoriatic arthritis, ankylosing spondylitis, and rheumatoid arthritis.[4]

Side Effects

Ustekinumab has been associated with injection site reaction and allergic adverse events. Upper respiratory airway infections have been reported.

JANUS KINASE INHIBITOR

The janus kinase (JAK)-signal transducer and activator of transcription (STAT) signaling pathway transmits information from various receptors at the cell surface, including those of cytokines, interferons, and growth factors, to the DNA promoters in the nuclei, thus stimulating cell activation and gene expression. The JAK family comprises several members, such as JAK1, JAK2, JAK3, and Tyk2, that are associated as heterodimers or homodimers to the different receptors. Tofacitinib (Xeljanz) is a competitive inhibitor of JAK autophosphorylation, leading to the absence of STAT phosphorylation by JAK and the nuclear translocation of STAT. Tofacitinib preferentially inhibits the signaling associated with JAK3 and JAK1 activation, including the receptors involved in the immune and inflammatory responses.

Indications

Tofacitinib is approved for the oral treatment of moderate and severe rheumatoid arthritis refractory to conventional DMARDs and TNF antagonists.[5] Tofacitinib can be used alone or in combination with conventional DMARDs. Clinical trials in psoriasis, psoriatic arthritis, Crohn disease, and ulcerative colitis are ongoing. The JAK½ inhibitor ruxolitinib was recently approved for the treatment of myelofibrosis.[6]

Adverse Effects

Tofacitinib is associated with an increased rate of infectious events, including different types of bacterial infections, herpes zoster, and opportunistic infections. Increase in transaminase levels, hypercholesterolemia, and cytopenia has also been observed. Some of these adverse effects are potentially related to the inhibition of signals induced by IL-6 and hematopoietic growth factors.

INHIBITORS OF ANGIOGENESIS

Vascular endothelial growth factor (VEGF) is a family of growth factors involved in vasculogenesis and angiogenesis. VEGF-A binds to the tyrosine kinase receptors, VEGFR1 and VEGFR2. VEGF has been implicated in tumor growth and metastasis, in diabetic retinopathy, and in age-related macular retinopathy.

Types of Angiogenesis Inhibitors

Bevacizumab (Avastin) is a humanized monoclonal antibody against VEGF that acts as an angiogenesis inhibitor. Aflibercept (Zaltrap) is a fusion protein containing extracellular immunoglobulin motifs of VEGFR1 and VEGFR2 coupled to human IgG1. Several VEGF receptor–associated tyrosine kinase inhibitors have been approved for the treatment of cancer, including Sorafenib (Nexavar), Sunitinib (Sutent), Axitinib (Inlyta), Pazopanib (Votrient), Vandetanib (Caprelsa), and Sorafenib (Nexavar). Some of these tyrosine kinase inhibitors block not only VEGF receptors but also platelet-derived growth factor receptor-β, c-Kit, and Flt3 receptor.

Indications

Bevacizumab is approved for the treatment of glioblastoma (Chapter 189), and also for some patients with non–small cell lung cancer (Chapter 191), and metastatic colorectal cancer (Chapter 193). In Europe, bevacizumab is also approved for metastatic breast and ovarian cancer therapy. Intraocular injections of ranibizumab (Lucentis), an antibody fragment derived from bevacizumab, are effective in maintaining vision in most patients with wet macular degeneration (Chapter 423) and are approved for this indication. Aflibercept is approved for the treatment of metastatic colorectal cancer. Sunitinib is approved for the treatment of metastatic renal cell carcinoma (Chapter 197), gastrointestinal stromal tumor refractory to imatinib (Chapter 202), and unresectable pancreatic neuroendocrine tumors. Axitinib and pazopanib are approved for the treatment of renal cell carcinoma. Pazopanib is also approved for advanced soft tissue sarcoma. Vandetanib is approved for late-stage medullary thyroid cancer. Sorafenib is approved for advanced renal cell carcinoma, some cases of hepatocarcinoma (Chapter 196), and late-stage thyroid cancer.

Adverse Effects

Bevacizumab has been associated with a heightened risk for bleeding and gastrointestinal tract perforation. Delayed wound healing and hypertension have also been reported. Reported adverse events for kinase inhibitors include hypertension, fatigue, asthenia, diarrhea, and some abnormal laboratory tests, including transaminases, lipase, amylase, and leukocytes and platelets. Vandetanib is associated with prolonged QT, and more rarely with cases of torsades de pointes and sudden death.

INHIBITORS OF TUMOR GROWTH FACTORS

The epidermal growth factor receptor (EGFR), a member of the ErbB-1 (human epithelial growth factor receptor-1 [HER-1]) family of receptors, is a cell surface receptor for epidermal growth factor (EGF) and transforming growth factor-α. Binding of EGFR leads to tyrosine kinase activation. In tumor cells, EGFR overexpression or dysregulation due to *EGFR* gene mutations (exon 19 deletion or exon 21 [L858R] substitution) can lead to cell proliferation, apoptosis blockade, neovascularization, and tumor metastasis. HER-2 (also known as ErbB2) is a receptor with tyrosine kinase activity that is expressed at high levels in 20 to 30% of breast cancers and other types of cancers and may cause uncontrolled tumor cell proliferation.

Types of Inhibitors

Two types of strategies target the EGFR pathway: monoclonal antibodies to the extracellular domain of EGFR and orally available tyrosine kinase inhibitors. Cetuximab (Erbitux) is a chimeric monoclonal IgG1 anti-EGFR antibody that inhibits EGFR signaling and may also induce tumor cell death by antibody-dependent cellular cytotoxicity. Panitumumab (Vectibix) is a fully human monoclonal IgG2 antibody directed against EGFR. Erlotinib (Tarceva), gefitinib (Iressa), and afatinib (Gilotrif) are the three most commonly studied EGFR tyrosine kinase inhibitors. Trastuzumab (Herceptin) is a humanized monoclonal IgG1 antibody that binds to the extracellular domain of HER-2. Lapatinib (Tykerb) is a small molecule with inhibitory activity on EGFR and HER-2 tyrosine kinases.

Indications

Cetuximab is approved as second- and third-line treatment in colorectal and squamous cell carcinoma of the head and neck cancers. Panitumumab is approved for the treatment of metastatic colorectal cancer. Erlotinib and afatinib are approved for the treatment of metastatic non–small cell lung carcinoma with EGFR mutations, whereas gefitinib is approved for the same indication but with some additional limitations. Erlotinib is also approved for the treatment of pancreatic cancer. Trastuzumab and lapatinib are approved for the treatment of metastatic breast cancer expressing HER-2, and trastuzumab for metastatic stomach and gastroesophageal junction cancer expressing HER-2.

Adverse Effects

Cetuximab is sometimes associated with severe allergic reactions during infusion. Acne-like skin rash has been commonly reported. Erlotinib, gefitinib, and afatinib are associated with acne-like rash and mild gastrointestinal symptoms. Cardiotoxicity is a major problem in patients treated with trastuzumab. Approximately 10% of patients are unable to tolerate this drug because of pre-existing heart problems. The risk for cardiomyopathy is increased when combined with anthracycline (which itself is associated with cardiac toxicity). Lapatinib is in general well tolerated, but some cases of hepatotoxicity have been reported. Active research is in progress to develop more selective angiogenesis inhibitors in order to overcome acquired resistance to specific inhibitors of VEGF and VEGFR and to reduce their negative off-target effects.[7]

OTHER TYROSINE KINASE INHIBITORS

Imatinib mesylate (Gleevec or Glivec) works by binding to the adenosine triphosphate (ATP) binding site of BCR-ABL, resulting in competitive inhibition of its enzymatic activity. Imatinib inhibits also the tyrosine kinase activity of c-Kit and platelet-derived growth factor receptor.

Indications

Imatinib represents a major advance over conventional treatments for chronic myelogenous leukemia (Chapter 184), with more than 90% of patients obtaining complete hematologic response and 70 to 80% of patients achieving a complete cytogenetic response. Resistance to imatinib[8] represents a clinical challenge and is often a result of point mutations causing a conformation change in BCR-ABL, which impairs imatinib binding. Dasatinib (Sprycel) and Nilotinib (Tasigna), two other tyrosine kinase inhibitors, have been approved for the treatment of chronic myelogenous leukemia as first-line therapy or in patients who are not responsive or intolerant to imatinib. Bosutinib (Bosulif) and ponatinib (Iclusig) are second-generation tyrosine kinase inhibitors that are approved as second-line treatment for chronic myelogenous leukemia.

Imatinib is also approved for the treatment of patients with c-Kit-positive advanced gastrointestinal stromal tumor (Chapter 202). Early clinical trials also showed potential beneficial effect of imatinib in systemic mastocytosis, hypereosinophilic syndrome, and dermatofibrosarcoma protuberans.

Adverse Effects

Imatinib has been associated with the occurrence of cytopenia, edema, nausea, and rash, as well as rare cases of congestive heart failure. Cytopenia and congestive heart failure are also reported with all tyrosine kinase inhibitors. Nilotinib also carries a potential risk for severe cardiac arrhythmias. Ponatinib is associated with severe adverse events, including arterial and venous blood clots, leading to its approval only in patients refractory to all other tyrosine kinase inhibitors or in patients who carry a specific gene mutation (*T315I*).

BIOLOGIC AGENTS TARGETING T LYMPHOCYTES

T cells play a central role in immune responses and are thus important targets for therapies against graft rejection and autoimmune diseases.

Types of Agents Modulating T-Cell Activity

The agents targeting T cells include antibodies against T cells, soluble receptors inhibiting costimulation signals, and antibodies blocking T-cell migration. Therapies targeting CD3 were developed more than 30 years ago with a mouse monoclonal IgG2 antibody called OKT3. These antibodies were used in the treatment of kidney transplant rejection but were associated with limiting side effects due to the occurrence of a "cytokine release syndrome." Then, a series of non-Fc-binding humanized anti-CD3 monoclonal antibodies were developed to overcome this problem as well as the development of antimurine immunoglobulin antibodies.

Abatacept (Orencia) and belatacept (Nulojix) are fusion proteins containing the extracellular portion of cytotoxic T lymphocyte antigen-4 coupled to the Fc portion of human IgG1, and they inhibit costimulatory signals between CD28 and CD80/86. Alefacept (Amevive) is a recombinant fully human fusion protein, in which the extracellular domain of CD2 has been linked to the Fc portion of IgG1, and it inhibits costimulatory signals between CD2 and LFA-3.

Natalizumab (Tysabri), a humanized monoclonal antibody against α_4-integrin, inhibits the migration of T cells by blocking the interaction between α_4-integrin and adhesion molecules expressed on endothelial cells.

Indications

Different monoclonal anti-CD3 antibodies are used in clinical trials for the prevention of transplant rejection (Chapter 49) as well as for the treatment of acute graft-versus-host disease and type 1 diabetes mellitus.

Abatacept is approved for the treatment of patients with rheumatoid arthritis and polyarticular juvenile idiopathic arthritis aged 6 years and older refractory to conventional DMARDs and TNF-α inhibitors. Belatacept is approved for the prevention of acute kidney transplant rejection. Alefacept is approved for the treatment of chronic plaque psoriasis. Natalizumab is approved for the treatment of patients with highly active remitting-relapsing multiple sclerosis in monotherapy (Chapter 411) and for severe Crohn disease.

Adverse Effects

Abatacept is generally well tolerated, but serious infectious adverse events may occur. Belatacept has been associated with anemia, urinary tract infections, and post-transplant lymphoproliferative disorders in Epstein-Barr virus–unexposed patients. Lymphopenia may occur with alefacept, and infections, malignancies, and hepatotoxicity have been reported in clinical trials. Natalizumab can be associated with allergic reactions and hepatotoxicity. Some cases of multifocal progressive leucoencephalopathy (Chapter 370), a fatal neurologic complication of JC virus reactivation in immunosuppressed individuals, have been reported, thus limiting the use of natalizumab.

AGENTS TARGETING B LYMPHOCYTES

The B-cell lineage plays a critical role in immune responses through the production of immunoglobulins, the presentation of antigen to T cells, and production of cytokines. Therapies aiming to target B cells are used in B-cell lymphoma and in autoimmune diseases.

Mode of Action

B cells can be targeted either by the use of monoclonal antibodies depleting B cells or by inhibiting cytokines essential for their maturation and survival, such as B-cell-activating factor of the TNF family (BAFF). Rituximab

(Rituxan or MabThera), ofatumumab (Arzerra), and ocrelizumab are B-cell-depleting monoclonal antibodies by binding to CD20. Belimumab (Benlysta) is a fully human monoclonal antibody against BAFF.

Indications

Rituximab is approved for the treatment of non-Hodgkin B-cell lymphoma (Chapter 185), for rheumatoid arthritis patients with inadequate response to TNF-α inhibitors, and in antineutrophil cytoplasmic autoantibody–associated vasculitis, including granulomatosis with polyangiitis (formerly Wegener granulomatosis) and microscopic polyangiitis. Disappointing results were obtained in clinical trials with rituximab in systemic lupus erythematosus. Ofatumumab is approved for the treatment of chronic lymphocytic leukemia (Chapter 184). Ocrelizumab is currently in clinical trials in multiple sclerosis. Epratuzumab, a humanized monoclonal anti-CD22 B-cell-depleting antibody, is in clinical trials for non-Hodgkin B-cell lymphoma. Positive results were reported in systemic lupus erythematosus, suggesting that epratuzumab might be eventually approved for this indication. Belimumab is the first biologic agent approved for the treatment of systemic lupus erythematosus refractory to conventional therapy. However, phase III studies leading to the registration of belimumab in this indication did not include more severe cases with renal and central nervous system involvement. Belimumab did not show efficacy in rheumatoid arthritis, but encouraging results were reported in Sjögren syndrome. The efficacy of tabalumab, a monoclonal antibody targeting membrane-bound and soluble BAFF, is being tested in a clinical trial in systemic lupus erythematosus.

Adverse Effects

Rituximab is associated with allergic reaction during infusions, systemic reaction due to tumoral B-cell lysis, and an increased risk for infectious events. Rare cases of multifocal progressive leucoencephalopathy have been reported. Hypogammaglobulinemia may occur, particularly after several series of infusions. Belimumab is associated with allergic reaction during infusion and an increased risk for infections.

CONCLUSION

The use of biologic agents has led to major advances in the management of many severe diseases refractory to conventional therapies. These agents have also provided a unique way to confirm the role of basic mechanisms in human diseases. New developments in this field will follow different directions, including the refinement of existing strategies (using more selective inhibitors or human rather than chimeric antibodies), the extension to other indications than those for which the agents were primarily designed, the selection of novel targets, and the identification of biologic markers of response.

REVIEW QUESTIONS

1. Which of the following TNF inhibitors has not shown efficacy in Crohn disease?

A. Infliximab
B. Adalimumab
C. Golimumab
D. Etanercept

Answer: D The monoclonal anti-TNF antibodies (A, B, and C) reduce disease activity and requirement for glucocorticoid therapy in Crohn disease. Etanercept is a fusion protein containing the extracellular portion of TNF-R75 coupled to the Fc domain of IgG1. In addition to binding TNF, it also binds lymphotoxin-α. For reasons that are not clarified, etanercept has not been efficacious in inflammatory bowel disease.

2. Previous or current infection with which one of the following microbial organisms should be assessed before initiating anti-TNF therapy?:

A. Meningococcus
B. Mycobacterium tuberculosis
C. Mycoplasma
D. Histoplasmosis

Answer: B Anti-TNF therapy has been associated with increased risk for reactivation of latent tuberculosis. Patients should be evaluated and appropriately treated for presence of tuberculosis infection before initiation of anti-TNF therapy. Although histoplasmosis has occasionally occurred in patients treated with anti-TNF agents, testing for infection with this organism in not routinely performed before initiating therapy.

3. A monoclonal antibody that inhibits the biologic activities of IL-12 and IL-23 has shown efficacy in which of the following diseases?

A. Psoriasis
B. Crohn disease
C. Systemic lupus erythematosus (SLE)
D. A and B
E. A, B, and C

Answer: D Ustekinumab has shown positive efficacy in trials in patients with psoriasis or Crohn disease. Although this agent might have potential use in SLE, data from clinical trials are not available.

4. Imatinib mesylate, a kinase inhibitor that has changed the prognosis of patients with chronic myelogenous leukemia, is also approved for which of the following diseases?

A. Scleroderma
B. Idiopathic pulmonary fibrosis
C. C-Kit-positive advanced gastrointestinal tumor
D. Rheumatoid arthritis
E. Inflammatory bowel disease

Answer: C Imatinib mesylate (Gleevec) has antifibrotic activity in some murine models, providing rationale for testing this agent in diseases such as scleroderma or idiopathic pulmonary fibrosis. However, randomized controlled clinical trials of this agent have not been performed in those diseases at this time.

5. Blockade of costimulatory signals between CD28 and CD80/86 has led to approval of abatacept in which of the following diseases?

A. Rheumatoid arthritis
B. Chronic myelogenous leukemia
C. Lupus nephritis
D. Crohn disease

Answer: A Abatacept (Orencia) has shown efficacy in rheumatoid arthritis, as well as a related disease in children, polyarticular juvenile idiopathic arthritis. Despite a strong rationale for costimulatory blockade in SLE, trials of this agent were not effective in lupus nephritis nor in those with non-nephritic manifestations. Crohn disease can be treated with an agent that blocks migration of T cells, natalizumab. Chronic myelogenous leukemia has a different molecular pathophysiology and is effectively targeted by specific tyrosine kinase inhibitors.

37

PROSTANOIDS, ASPIRIN, AND RELATED COMPOUNDS

CARLO PATRONO

Arachidonic acid, or 5,8,11,14-eicosatetraenoic acid, is a 20-carbon polyunsaturated fatty acid esterified in the phospholipid domain of cell membranes. In response to chemical, physical, and hormonal stimuli, arachidonic acid is released from the glycerol backbone sn2 position by the action of various phospholipases A_2 and can be subjected to rapid enzymatic conversion to a series of oxygenated derivatives collectively called eicosanoids. The enzymes catalyzing various structural modifications of free arachidonic acid include prostaglandin H synthases, commonly known as cyclooxygenases (COX), lipoxygenases, and cytochrome P-450 isozymes. The resulting eicosanoids include prostanoids (prostaglandins and thromboxane A_2), leukotrienes, lipoxins, and epoxylins. Esterified arachidonic acid can also be subjected to in situ peroxidation, catalyzed by oxygen radicals, to form a series of corresponding isomers called isoeicosanoids.

Eicosanoids are not stored but are produced in response to diverse stimuli, with a pattern that reflects the cell-specific distribution of arachidonic acid–metabolizing enzymes and downstream isomerases and synthases. Eicosanoids are not circulating hormones but rather ubiquitous autacoids that modulate the intensity and duration of many important cellular responses in an autocrine (acting on the same cells that produced them) or paracrine (acting on nearby cells) fashion.

BIOSYNTHESIS AND ACTION OF PROSTANOIDS

Prostanoids include prostaglandins D_2, E_2, $F_{2\alpha}$, and I_2 (prostacyclin) and thromboxane A_2. They are formed through the sequential actions of phospholipase A_2 to release arachidonic acid from membrane phospholipids, prostaglandin H synthase to catalyze the cyclooxygenation of arachidonic acid to form the unstable intermediate prostaglandin G_2 and its reduction to prostaglandin H_2, and specific isomerases and synthases to catalyze the conversion of prostaglandin H_2 to different prostanoids (Fig. 37-1). Once formed, prostanoids interact with specific G protein–coupled receptors to evoke a variety of cellular responses, depending on the site of their biosynthesis (Fig. 37-1).

Two prostaglandin H synthases have been identified: prostaglandin H synthase 1 is expressed constitutively in all cells; prostaglandin H synthase 2 is constitutively expressed in some cells (e.g., neurons and renal cells) and is induced in other cell types in response to cytokines (e.g., in monocytes), tumor promoters (e.g., in intestinal epithelial cells), growth factors (e.g., in bone marrow–derived stem cells), and laminar shear stress (e.g., in endothelial cells). Because nonsteroidal anti-inflammatory drugs (NSAIDs) target the COX activity of these enzymes, they have become known colloquially as COX-1 and COX-2.[1] Both enzymes are homodimers that convert arachidonic acid, two oxygen molecules, and two electrons from one or more unknown reductants to prostaglandin H_2. COX-1 and COX-2 are found predominantly in the same cellular organelles, at the luminal surface of the endoplasmic reticulum and nuclear envelope of cells. Only one monomer of a dimer catalyzes arachidonic acid oxygenation at any given time. The cross-talk between monomers serves as a way for COX-2 to exhibit selectivity toward arachidonic acid, even when it is a minor component of the available fatty acid pool, and to sustain a "late phase" of prostanoid production. In contrast, COX-1 may efficiently oxygenate arachidonic acid in the early phase of prostanoid production, when this substrate represents a large fraction of free fatty acids, but may be inhibited by other competing fatty acids in the late phase.

Phenotypical analyses of COX-1–deficient and COX-2–deficient mice as well as studies with isoform-selective inhibitors suggest that there are processes in which each isozyme is uniquely involved (e.g., platelet aggregation for COX-1, ovulation and neonatal development for COX-2) and others in which both isozymes function coordinately (e.g., inflammation and its resolution, gastrointestinal ulceration and healing, and carcinogenesis). A way in which the two biosynthetic pathways may be dissociated metabolically is by a preferential coupling of the COX isozymes to various upstream phospholipases and downstream synthases, conditioning preferential formation of a particular prostanoid by a given cell type (e.g., COX-2–dependent prostacyclin by vascular endothelial cells).

Moreover, COX-2 oxygenation may play a unique role in a novel signaling pathway dependent on agonist-induced release of endocannabinoids.[2] Among the products of COX-2 oxygenation of endocannabinoids are glyceryl prostaglandins, some of which (e.g., glyceryl prostaglandin E_2 and glyceryl prostaglandin I_2) exhibit interesting biologic activities in inflammatory, neurologic, and vascular systems.

MEASUREMENTS OF THE PROSTAGLANDIN H SYNTHASE PATHWAY

Prostanoids are formed in vivo at a relatively low rate (e.g., 0.1 ng/kg per minute for both prostacyclin and thromboxane A_2) and are metabolized extensively by lung and liver enzymes to form chemically stable but biologically inactive derivatives that are excreted primarily through the kidney. Given the chemical instability and extremely low concentrations (1 to 2 pg/mL) of prostanoids in the systemic circulation, assessment of their production in humans is largely based on measurements of stable urinary metabolites (e.g., 11-dehydro-thromboxane B_2, a major enzymatic derivative of thromboxane A_2, and 2,3-dinor-6-keto-$PGF_{1\alpha}$, a major enzymatic derivative of prostacyclin). These analytical measurements have established that thromboxane metabolite excretion is primarily derived from platelet

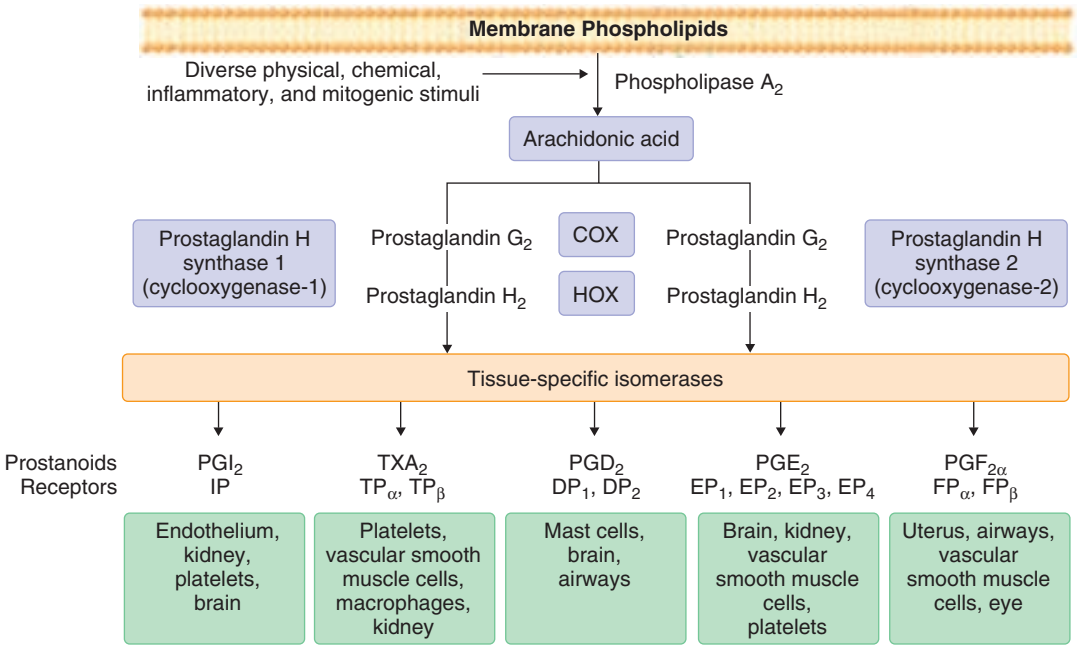

FIGURE 37-1. Production and actions of prostaglandins and thromboxane. Arachidonic acid, a 20-carbon fatty acid containing four double bonds, is liberated from the sn2 position in membrane phospholipids by phospholipase A_2, which is activated by diverse stimuli. Arachidonic acid is converted by prostaglandin H synthases, which have both cyclooxygenase (COX) and hydroperoxidase (HOX) activity, to the unstable intermediate prostaglandin H_2. The synthases are colloquially termed cyclooxygenases and exist in two forms, cyclooxygenase 1 and cyclooxygenase 2. Prostaglandin H_2 is converted by tissue-specific isomerases to multiple prostanoids. These bioactive lipids activate specific cell membrane receptors of the superfamily of G protein–coupled receptors. Some of the tissues in which individual prostanoids exert prominent effects are indicated. DP = prostaglandin D_2 receptor; EP = prostaglandin E_2 receptor; FP = prostaglandin $F_{2\alpha}$ receptor; IP = prostacyclin receptor; TP = thromboxane receptor.

thromboxane biosynthesis and largely reflects the rate of platelet activation in vivo. Similarly, prostacyclin metabolite excretion largely reflects the rate of vascular prostacyclin biosynthesis in vivo. Thromboxane biosynthesis is persistently enhanced in association with the major cardiovascular risk factors (e.g., diabetes mellitus). The biosynthesis of both thromboxane and prostacyclin is episodically increased in patients with acute coronary syndromes, perhaps reflecting a homeostatic response to accelerated platelet-vascular interactions.

Studies of the human pharmacology of COX inhibitors have largely relied on the development of whole blood assays of platelet COX-1 (based on serum thromboxane B_2 measurements) and monocyte COX-2 (based on lipopolysaccharide-induced prostaglandin E_2 production) activities. These assays have been useful in characterizing the variable potency of NSAIDs in inhibiting COX-1 and COX-2 in vitro (a measure of isozyme selectivity) and in determining ex vivo the dose and time dependence of their inhibitory effects in health and disease.

CLINICAL PHARMACOLOGY OF PROSTAGLANDIN H SYNTHASE INHIBITION

Most traditional NSAIDs inhibit COX-1 and COX-2 with similar potency (Fig. 37-2). Some traditional NSAIDs (e.g., nimesulide and diclofenac) and a class of COX-2 inhibitors called coxibs (e.g., celecoxib and etoricoxib) are more potent in inhibiting COX-2 than COX-1 (Fig. 37-2). These drugs fall into three general categories on the basis of their mechanism of action. One category of inhibitors includes freely reversible competitive inhibitors, such as ibuprofen and mefenamic acid. Binding of these inhibitors to the COX sites of both monomers composing a dimer is required for inhibition of COX-2 oxygenation of the substrate. A second group of inhibitors, including flurbiprofen, meclofenamate, diclofenac, and indomethacin, comprises time-dependent, noncovalent inhibitors. These NSAIDs are allosteric inhibitors that bind to one monomer of COX to inhibit its activity. Aspirin is unique to a third group of inhibitors that cause a time-dependent, covalent inhibition. Binding of aspirin to COX-1 or COX-2 leads to irreversible acetylation of a highly conserved serine residue (Ser-529 and Ser-516 in human COX-1 and COX-2, respectively). Aspirin acetylates only one monomer of a COX-1 dimer to cause complete loss of COX activity. Aspirin also maximally acetylates one monomer of human COX-2. The acetylated monomer of aspirin-treated COX-2 forms 15-hydroperoxyeicosatetraenoic acid from arachidonic acid, whereas the nonacetylated partner monomer forms mainly prostaglandin H_2 but only at 15 to 20% of the rate of native COX-2. Thus, the effect of aspirin on COX-2 is an incomplete allosteric inhibition compared with that seen with COX-1.

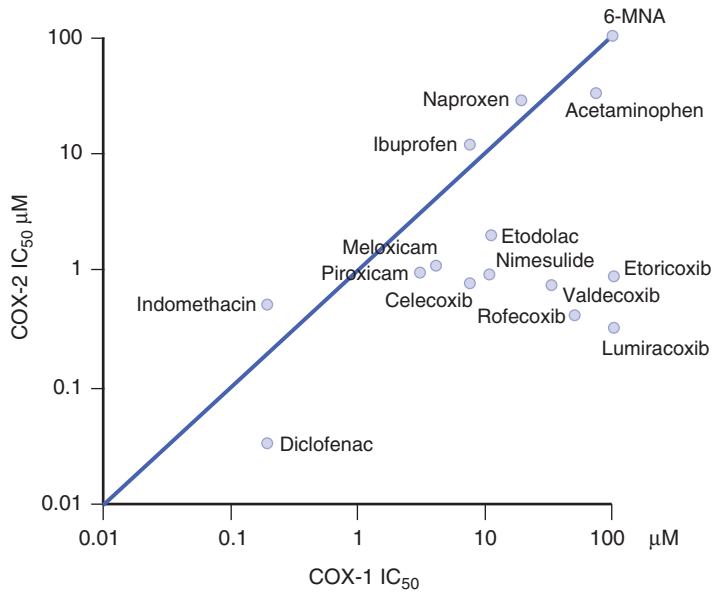

FIGURE 37-2. COX-2 selectivity as a continuous variable. Concentrations of various COX-2 inhibitors to inhibit the activity of platelet COX-1 and monocyte COX-2 by 50% (IC_{50}) are plotted on the abscissa and ordinate scales, respectively. The *solid line* describes equipotent inhibition of both COX-1 and COX-2. Symbols to the left of this line denote greater inhibition of COX-1 than of COX-2. Symbols to the right of this line indicate progressively greater inhibition of COX-2 than of COX-1, that is, increasing degrees of COX-2 selectivity. Aspirin is not shown on the figure because the long-term incubation required for monocyte COX-2 expression in human whole blood affects the chemical stability of the drug and underestimates its inhibitory potency. 6-MNA = 6-methoxy-2-naphthylacetic acid, the active metabolite of nabumetone.

Traditional NSAIDs typically inhibit platelet COX-1 and monocyte COX-2 by 50 to 90%, depending on dose; this effect is usually transient, depending on dose and half-life (Fig. 37-3). Coxibs inhibit monocyte COX-2 to the same extent as other NSAIDs while substantially sparing platelet (and presumably other cells) COX-1 in most patients exposed to therapeutic

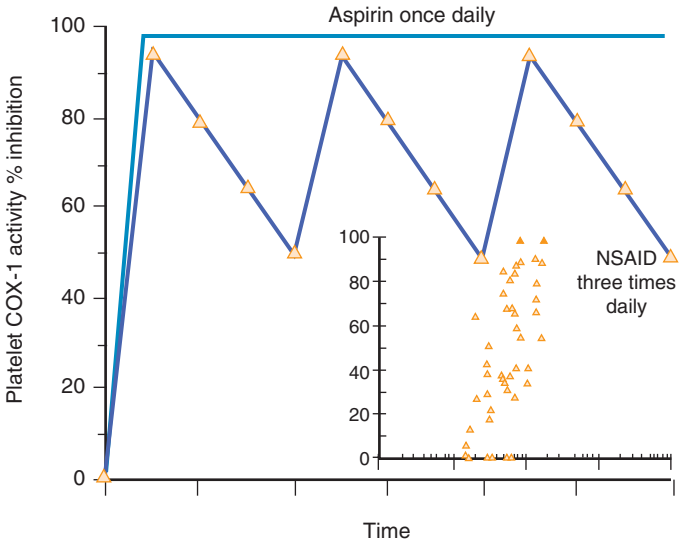

FIGURE 37-3. Time-dependent inhibition of platelet COX-1 activity by aspirin and a traditional nonsteroidal anti-inflammatory drug (NSAID). The average time course of inhibition of serum thromboxane B_2, an ex vivo index of platelet COX-1 activity, is depicted during 24 hours after the administration of low-dose aspirin once daily and a traditional NSAID with short half-life given every 8 hours. The *inset* depicts the interindividual variability in the relationship between NSAID plasma levels plotted on the abscissa log scale and the corresponding level of inhibition of platelet COX-1 plotted on the ordinate.

doses. In contrast, aspirin achieves virtually complete (i.e., >97%) and persistent (i.e., ≥24 hour) inactivation of platelet COX-1 by virtue of its irreversible mechanism of action and inability of anucleate platelets to resynthesize the enzyme. Aspirin is equally potent in acetylating COX-1 and COX-2 in vitro. However, its unique mechanism of action and unusual pharmacokinetic features (20-minute half-life; presystemic encounter with the platelet target in the portal blood before first-pass liver metabolism) allow selective, cumulative inhibition of platelet COX-1 at low doses while substantially sparing vascular COX-2. The effect of aspirin on COX-1–dependent thromboxane A_2 production is saturable at daily doses as low as 30 to 50 mg; in contrast, its inhibitory effect on COX-2–dependent prostaglandin I_2 biosynthesis is dose dependent up to daily doses of 650 to 1300 mg.

The relationships among inhibition of COX isozyme activity, reduced prostanoid formation, and changes in prostanoid-dependent cell function in vivo are not necessarily linear. The strikingly nonlinear relationship between inactivation of platelet COX-1 and inhibition of thromboxane-dependent platelet activation in vivo has important clinical implications for the cardiovascular effects of low-dose aspirin versus traditional NSAIDs (see later). In addition, interindividual variability in drug plasma levels as well as in the corresponding level of COX isozyme inhibition contributes to substantial unpredictability of the individual clinical response to COX inhibitors (E-Fig. 37-1).

Low-Dose Aspirin as an Antithrombotic and Anti-Cancer Agent

Antithrombotic Effects

The efficacy and safety of aspirin as an antithrombotic agent have been evaluated in several populations, ranging from apparently healthy persons at low risk of vascular complications (so-called primary prevention) to high-risk patients presenting with or surviving an acute myocardial infarction or an acute ischemic stroke (so-called secondary prevention). The clinical efficacy of aspirin was demonstrated at doses ranging from 50 to 162 mg given once daily (Table 37-1), consistent with the irreversible nature of its mechanism of action. Furthermore, higher doses (e.g., 300 to 325 mg) were not found to confer additional benefits, consistent with saturability of platelet COX-1 acetylation at low doses.[3,4]

In the six primary prevention trials among 95,000 low-risk individuals, aspirin allocation yielded a 12% relative risk reduction in serious vascular events (myocardial infarction, stroke, or vascular death). This protective effect was mainly due to a reduction in nonfatal myocardial infarction. The net effect on stroke was not significant, reflecting a small reduction in ischemic stroke and counterbalancing effects on hemorrhagic stroke. There was no significant reduction in vascular mortality. Aspirin increased gastrointestinal (or other extracranial) bleeds by approximately 50%. The balance of cardiovascular benefits and bleeding risk associated with low-dose aspirin in specifically primary prevention is uncertain.[5]

TABLE 37-1 VASCULAR DISORDERS FOR WHICH ASPIRIN HAS BEEN SHOWN TO BE EFFECTIVE AND THE LOWEST EFFECTIVE DOSE

DISORDER	LOWEST EFFECTIVE DAILY DOSE (mg)
TIA and ischemic stroke*	50
Men at high cardiovascular risk	75
Essential hypertension	75
Chronic stable angina	75
Unstable angina or NSTEMI*	75
Severe carotid artery stenosis*	75
Polycythemia vera	100
Acute ischemic stroke*	160
Acute STEMI	162

*Higher doses were tested and not found to confer any greater risk reduction.
NSTEMI = non–ST elevation myocardial infarction; STEMI = ST elevation myocardial infarction; TIA = transient ischemic attack.

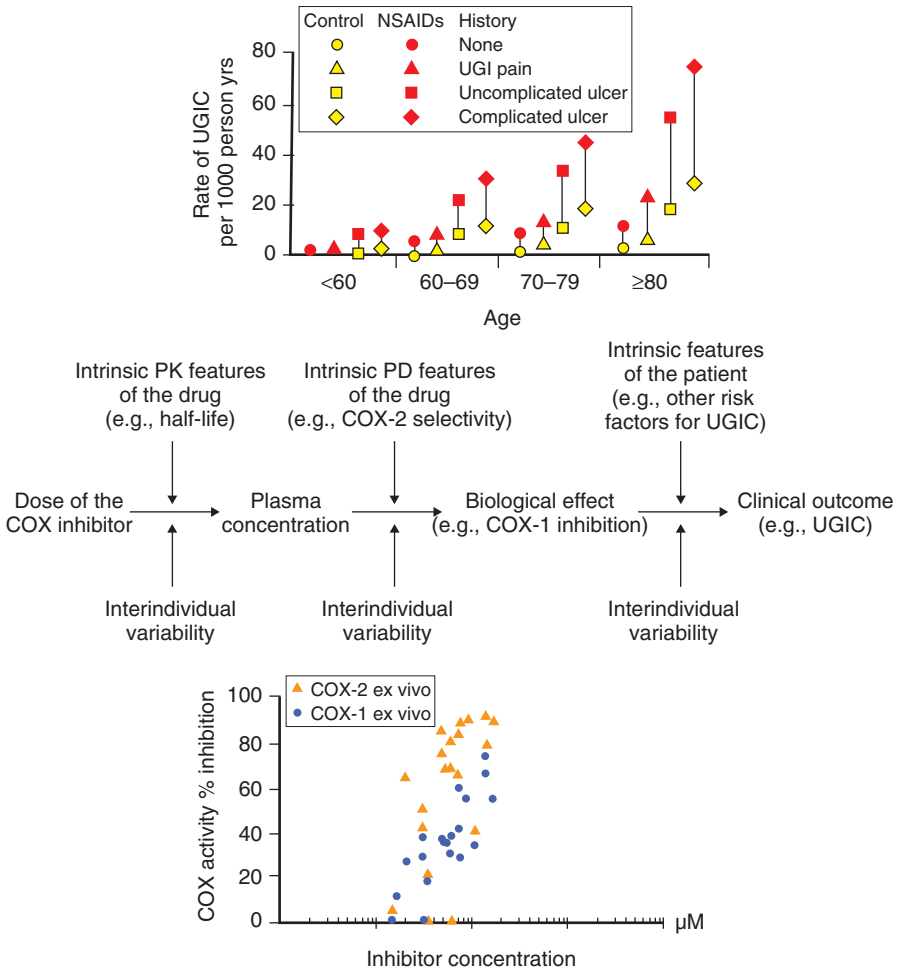
In 16 secondary prevention trials in 17,000 high-risk patients with prior myocardial infarction, or prior stroke or transient cerebral ischemia, aspirin allocation yielded 19% fewer serious vascular events, with similar proportional reductions in coronary events (20% relative risk reduction) and ischemic stroke (22% relative risk reduction) but a nonsignificant increase in hemorrhagic stroke. The absolute benefit of aspirin was about 25 times larger in secondary than in primary prevention (15 vs. 0.6 fewer vascular events per 1000 per year). In both primary and secondary prevention trials, the proportional reductions in serious vascular events appeared similar for men and women and for older and younger people. The risks of serious vascular events and of major extracranial bleeds were predicted by the same independent risk factors (age, male gender, diabetes mellitus, current smoking, blood pressure, and body mass index), so those with high risk of vascular complications also had a high risk of bleeding. For secondary prevention of cardiovascular disease, the net benefits of adding aspirin to other preventive measures (e.g., statins) substantially exceed the bleeding hazards, irrespective of age and gender.

Anti-Cancer Effects

Aspirin, 75 mg daily or more for at least several years, reduces the incidence and mortality of colorectal cancer. Long-term follow-up of randomized vascular prevention trials of daily aspirin versus control showed that aspirin reduced not only the incidence of and mortality due to colorectal cancer but also death due to several other common cancers. Furthermore, meta-analysis has shown short-term reduction by daily aspirin in cancer incidence and mortality in women as well as in men and in non-smokers as well as in smokers. In a randomized trial of carriers of hereditary colorectal cancer genes, aspirin (600 mg daily) for a mean of 25 months substantially reduced the incidence of cancer after about 5 years. Low-dose aspirin also reduces the risk of metastases, especially for adenocarcinomas. The mechanism underlying the chemopreventive effect of low-dose aspirin might involve inhibition of platelet activation.[6] More recent evidence shows that the risk of major bleeding with aspirin diminishes with prolonged use, suggesting that the balance of risk and benefit favors the use of daily aspirin in primary prevention of colorectal and other cancers.[7] A regulatory review of the existing evidence as well as treatment guidelines are needed for this potential chemopreventive strategy.

Traditional Nonsteroidal Anti-inflammatory Drugs and Coxibs

NSAIDs constitute a chemically heterogeneous group of compounds that provide symptomatic relief of pain and inflammation associated with a variety of human disorders, including the rheumatic diseases. Their shared therapeutic actions (i.e., analgesic, anti-inflammatory, and antipyretic) are usually accompanied by mechanism-based adverse effects on gastrointestinal, cardiovascular, and renal functions. Prostanoids reproduce the main signs and symptoms of the inflammatory response and cause hyperalgesia and fever. Because of the redundancy of mediators of these responses, it is not surprising that NSAIDs exert only a moderate anti-inflammatory effect, are effective only against pain of low to moderate intensity, and reduce fever but do not interfere with the physiologic control of body temperature. The analgesic, anti-inflammatory, and antipyretic actions of traditional NSAIDs are largely reproduced by coxibs, a class of selective inhibitors of COX-2.



E-FIGURE 37-1. Determinants and sources of variability in the complications of COX-inhibitory drugs. Major determinants of the likelihood of an upper gastrointestinal complication (UGIC) resulting from administration of a cyclooxygenase (COX) inhibitor include pharmacokinetic (PK) and pharmacodynamic (PD) variables as well as the interaction of the drug with preexisting risk factors for UGIC. PK features, such as half-life of the drug, and PD features, such as its selectivity for the COX-2 isoform, are intrinsic to the COX inhibitor. The presence or absence of risk factors for UGIC will clearly vary between patients. Significant interindividual variability arises from several sources and is superimposed on each of these effects. In addition to the variable plasma levels achieved after oral dosing of a COX inhibitor, the inhibition of the platelet COX-1 isozyme (*circles*) and the monocyte COX-2 isozyme (*triangles*) in response to any given plasma level of the inhibitor is highly variable in individual subjects, as shown in the lower panel. The estimated rates of UGIC in women, according to age and the presence or absence of a history of such complications and regular use of NSAIDs, are represented in the upper panel. The solid lines connecting each pair of yellow and red symbols depict the absolute excess of complications related to NSAID therapy.

COX-2 selectivity is a continuous variable (see Fig. 37-2). Thus, one can pragmatically characterize three levels of COX-2 selectivity in terms of the probability of sparing COX-1 at therapeutic plasma levels: low (e.g., acetaminophen), intermediate (e.g., celecoxib, nimesulide, and diclofenac), and high (e.g., rofecoxib, etoricoxib, and lumiracoxib).

Drug Interactions

NSAIDs can modify the pharmacokinetics or pharmacodynamics of other drugs given concurrently, resulting in clinically important drug interactions. A pharmacodynamic interaction may occur between most NSAIDs and several classes of antihypertensive drugs. Reduced production of vasodilator prostacyclin and natriuretic prostaglandin E_2, as a consequence of renal COX-2 inhibition, results in vasoconstriction and sodium and water retention that in turn tend to elevate blood pressure, regardless of the mechanism of action of antihypertensive drugs. This pharmacodynamic interaction has been described with most traditional NSAIDs (including acetaminophen) and coxibs, but not with low-dose aspirin.

Some NSAIDs favoring COX-1 over COX-2 inhibition, such as ibuprofen and naproxen, may interfere with the antiplatelet effect of low-dose aspirin by competing with acetylsalicylic acid for a common docking site (arginine-120) within the COX-1 channel. Drugs favoring COX-2 versus COX-1 inhibition, such as acetaminophen and diclofenac, do not interfere with the pharmacodynamic effect of low-dose aspirin, similar to celecoxib and rofecoxib.

Gastrointestinal and Bleeding Complications

Upper gastrointestinal complications (bleeds, perforations, and obstructions)[8,9] occur in 1 to 2% of NSAID-treated patients (Chapter 139). The mortality rate associated with hospitalization due to major gastrointestinal events is 5 to 6% in recent studies. Mortality rates associated with upper or lower gastrointestinal complications due to NSAIDs are similar. The major risk factors for upper gastrointestinal bleeding are represented by age and a prior history of gastrointestinal disorders (E-Fig. 37-1). Male gender, cigarette smoking, and heavy alcohol intake increase this risk by less than two-fold, as do oral glucocorticoids. Oral anticoagulants, thienopyridines, and low-dose aspirin increase the risk of NSAID-induced bleeding complications by two- to three-fold. The excess of these complications due to traditional NSAIDs has been estimated to range between 3 and 30 events per 1000 patients treated per year, depending on the absence or presence of risk factors (E-Fig. 37-1).

Highly selective COX-2 inhibitors are associated with a statistically significant 50 to 66% relative risk reduction in ulcer complications compared with naproxen or ibuprofen. However, no such agent is currently available on the U.S. market.

Cardiovascular Complications

A meta-analysis of individual participant data from randomized trials of five different coxibs has revealed that in placebo comparisons, allocation to a coxib was associated with a 37% increased risk of major vascular events with no statistically significant heterogeneity among the different coxibs.■ This excess risk of vascular events was derived primarily from a two-fold increased risk of myocardial infarction. Overall, there was no significant difference in the incidence of vascular events between a coxib and any traditional NSAID, but there was evidence of significant heterogeneity between naproxen and the other traditional NSAIDs (largely represented by ibuprofen and diclofenac). The proportional effects on major vascular events were independent of baseline characteristics, including vascular risk. Therefore, the absolute excess of major vascular events caused by coxibs and some traditional NSAIDs varied between 2 and 9 for every 1000 patients allocated to a year of treatment, depending on the baseline level of cardiovascular risk.

Current evidence suggests that the risk of myocardial infarction depends on the extent of COX-2 inhibition and not on the variable COX-2 selectivity of the inhibitor.[10] This risk appears to be modulated by concomitant high-grade and persistent inhibition of platelet COX-1 activity, as suggested by the neutral cardiovascular phenotype associated with a high-dose regimen of naproxen.■ However, in patients at high cardiovascular risk, whose platelet COX-1 is completely and persistently inactivated by low-dose aspirin, the administration of any COX-2 inhibitor (including naproxen) is likely to produce detrimental cardiovascular consequences.

Given the nonlinear relationship between inhibition of platelet COX-1 activity and inhibition of platelet activation in vivo, it is perhaps not surprising that the cardiovascular safety profiles of coxibs and some traditional NSAIDs (e.g., diclofenac) appear similar because they both fail to inhibit platelet activation adequately irrespective of their COX-2 selectivity. Early appearance, dose dependence, and slow dissipation of risk are important features of COX-2-related cardiotoxicity.

REVIEW QUESTIONS

1. The concomitant administration of which of the following drugs can interfere with the antiplatelet effect of low-dose aspirin?

A. All traditional nonsteroidal anti-inflammatory drugs (NSAIDs)
B. Celecoxib
C. Ibuprofen and naproxen
D. Acetaminophen
E. Diclofenac

Answer: C Ibuprofen and naproxen are somewhat more potent in inhibiting COX-1 than COX-2 (as shown in Fig. 37-2) and can compete with aspirin for binding to a common docking site within the COX-1 channel, thereby interfering with permanent acetylation of the platelet enzyme. Other COX inhibitors that have some degree of COX-2 selectivity, such as celecoxib, acetaminophen, and diclofenac, do not display this pharmacodynamic interaction.

2. Which of the following is true regarding the increased risk for major vascular events associated with the use of COX-2 inhibitors?

A. The increased risk is restricted to coxibs.
B. The increased risk is shared by all NSAIDs.
C. The increased risk is related to COX-2 selectivity.
D. The increased risk is shared by NSAIDs that do not adequately inhibit platelet COX-1 activity.
E. The increased risk requires a treatment duration of at least 18 months.

Answer: D Coxibs and traditional NSAIDs that do not adequately inhibit platelet COX-1 activity (e.g., diclofenac and ibuprofen) similarly increase the risk for major vascular events, regardless of their variable COX-2 selectivity. The increased risk appears early and does not require prolonged exposure. See reference A6.

3. The main features of the antithrombotic effect of low-dose aspirin include which of the following?

A. Saturability of the effect at low doses
B. A lowest effective daily dose in the range of 160 to 325 mg
C. Differential effects in men versus women
D. Differential effects in older versus younger subjects
E. None of the above

Answer: A As indicated in Table 37-1, the lowest effective daily dose is in the range of 50 to 162 mg. The antithrombotic effect of aspirin is saturable at such low doses, inasmuch as higher doses were tested and not found to confer any greater risk reduction. The effect is similar in men and women, as well as in subjects younger and older than 65 years.

4. Prostaglandin H synthases do which of the following?

A. Catalyze the conversion of PGH_2 to PGE_2
B. Catalyze the first committed step in prostanoid biosynthesis from arachidonic acid
C. Catalyze the release of arachidonic acid from membrane phospholipids
D. Are inhibited irreversibly by all NSAIDs
E. None of the above

Answer: B As shown in Figure 37-1, prostaglandin H synthases catalyze the conversion of arachidonic acid to PGG_2 and its reduction to PGH_2, that is, the first committed step in prostanoid biosynthesis. Other enzymes catalyze the release of arachidonic acid from membrane phospholipids and the conversion PGH_2 to PGE_2. Aspirin, but not other NSAIDs, inhibits prostaglandin H synthases irreversibly.

5. Which of the following is true of low-dose aspirin and traditional NSAIDs?

A. They share the same molecular mechanism of permanent inactivation of COX-isozymes.
B. They share the same pharmacologic effects.
C. They differentially inhibit platelet COX-1 activity as a function of their mechanism of action and half-life.
D. They have the same cardiovascular effects.
E. None of the above

Answer: C As show in Figure 37-3, low-dose aspirin and a traditional NSAID with a short half-life (e.g., ibuprofen) differentially inhibit platelet COX-1 activity during the dosing interval because of the irreversible versus reversible mechanism of action. Aspirin is primarily an antiplatelet agent at low doses administered once daily and requires higher doses and more frequent dosing to produce the same pharmacologic effects of traditional NSAIDs. The cardioprotective effects of low-dose aspirin are not shared by traditional NSAIDs.

38

ANTITHROMBOTIC THERAPY

SAM SCHULMAN AND JACK HIRSH

Antithrombotic therapy suppresses the natural hemostatic mechanisms (Chapter 171) and is effective for preventing and treating venous, cardiac, and arterial thromboembolism. A variety of medications are now available that interfere with different steps in coagulation and platelet activation, sometimes with synergistic effects. Randomized clinical trials have produced a substantial body of evidence-based literature to guide the use of antithrombotic therapy for a wide range of clinical conditions. Updated recommendations have been published in the new 2012 American College of Chest Physicians (ACCP) evidence-based clinical practice guidelines, 9th edition (also accessible at http://journal.publications.chestnet.org/ss/guidelines.aspx). (See Grade A Recommendations for Antithrombotic Therapy at the end of the text in this chapter.)

PHARMACOLOGIC AGENTS

Vitamin K Antagonists

For more than 60 years, vitamin K antagonists have been the only oral anticoagulants available for clinical use. Now, with the development of new oral agents that target single coagulation enzymes (see later), the situation is changing. Coumarins are vitamin K antagonists, of which warfarin is the most widely used. Coumarins inhibit a vitamin K reductase that catalyzes the reduction of 2,3-epoxide (vitamin K epoxide), thereby leading to the depletion of vitamin KH_2, which is required for the production of functionally active (γ-carboxylated) coagulation proteins (factors II [prothrombin], VII, IX, and X) and anticoagulant proteins (protein C and protein S) (Chapter 175). Vitamin K_1 in food sources can reverse these effects of coumarins because it is reduced to vitamin KH_2 by a warfarin-insensitive vitamin K reductase (Fig. 38-1).

Warfarin is rapidly and almost completely absorbed from the gastrointestinal tract. It has a half-life of about 40 hours, a delayed onset of action (2 to 7 days, depending on dose), and a residual anticoagulant effect for up to 5 days after treatment is discontinued. The dose-response relationship of warfarin varies widely among individuals and is influenced by many factors, including age, body weight, liver disease, dietary vitamin K_1, genetic factors, concomitant drug use, compliance of the patient, and inappropriate dosage adjustments. Of these factors, inappropriate dosage adjustment and improved compliance through patient education are the most readily correctable.

The effect of warfarin must be monitored closely to prevent overdosing or underdosing. Laboratory monitoring is performed by measuring the

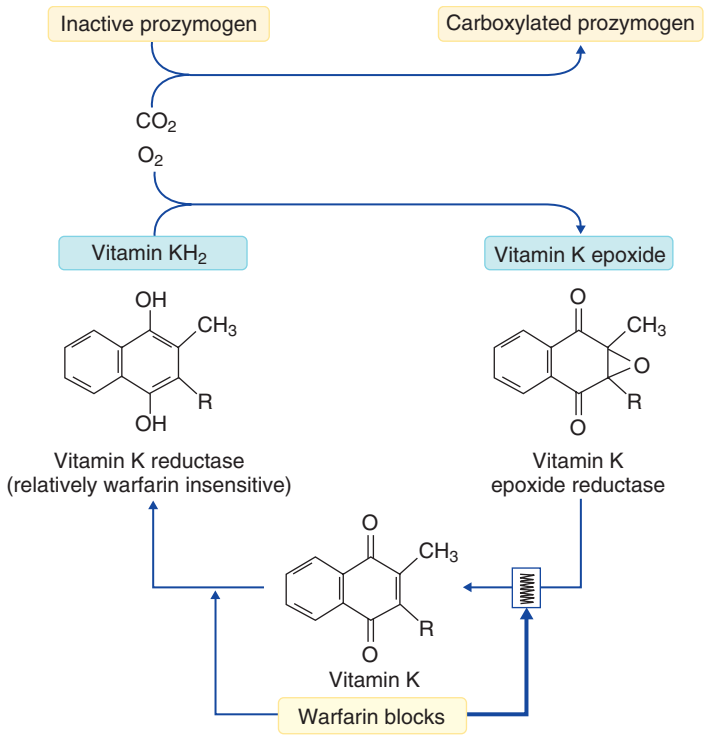

FIGURE 38-1. Warfarin inhibits vitamin K epoxide reductase and leads to the intracellular depletion (in the hepatocyte) of vitamin KH_2. Vitamin KH_2 is required for the conversion (by γ-carboxylation) of functionally inactive to active coagulation proteins. The anticoagulant effect of warfarin can be reversed by vitamin K_1 in food because it is reduced to vitamin KH_2 by a warfarin-insensitive vitamin K reductase.

prothrombin time and is reported as an international normalized ratio (INR). During initiation of warfarin therapy, the INR reflects primarily the depression of factor VII, which has a half-life of only 6 hours. The reliability of warfarin monitoring appears to be improved by using paper nomograms or computer-assisted algorithms. The convenience of monitoring is increased with a portable point-of-care instrument. Pharmacogenetic-guided dosing of warfarin has been evaluated in four randomized trials without producing evidence that the rate of major hemorrhage or thromboembolic complications is reduced, and the current cost is $100 to $200 per patient. The 2012 ACCP practice guidelines (http://journal.publications.chestnet.org/ss/guidelines.aspx) summarize published literature concerning the laboratory and clinical characteristics of vitamin K antagonists.

Indications for Warfarin

Warfarin is effective in the primary and secondary prevention of systemic embolism in patients with atrial fibrillation (Chapter 64),[■] with rheumatic mitral valve complicated stenosis or by left atrial thrombus[■]; with bioprosthetic or mechanical heart valves (Chapter 75); in the primary and secondary prevention of venous thromboembolism (VTE) (Chapters 81 and 98); in the prevention of acute myocardial infarction in high-risk patients (Chapters 72 and 73); and in the prevention of stroke (Chapter 407), recurrent infarction, and death in patients with acute myocardial infarction (Chapter 73). A target INR of 2.5 (range, 2.0 to 3.0) is recommended for almost all indications. Exceptions are mechanical prosthetic heart valve in the mitral position or caged-ball or caged-disk valve in the aortic position or any mechanical aortic valve in combination with atrial fibrillation, anterior myocardial infarction, left atrial enlargement, or low ejection fraction, when an INR of 3.0 (range, 2.5 to 3.5) is recommended.

Dosing and Monitoring

If a rapid anticoagulant effect is required, heparin and warfarin should be started at the same time and overlapped for at least 5 days. Warfarin is started with the estimated maintenance dose of about 5 mg/day, with the first INR measurement after 2 to 3 days, and patients usually reach an INR of 2.0 in 4 or 5 days. If there is no increase of the INR after two or three doses, the daily dose should be progressively increased until an INR response is observed. In patients with a low risk for bleeding, warfarin may be started at a dose of 10 mg and then adjusted according to daily INR results. Heparin treatment is discontinued when the INR has been in the therapeutic range for 2 days.

TABLE 38-1 RECOMMENDED MANAGEMENT OF ELEVATED INR WITH OR WITHOUT BLEEDING IN PATIENTS TREATED WITH WARFARIN

INR	BLEEDING	WARFARIN	VITAMIN K_1	FFP/PCC/rFVIIa
<5.0	Negligible	Hold 1 dose or reduce dose	No	No
5.0-9.9	Negligible	Hold 1-2 doses	Generally no*	No
≥10	Negligible	Hold	2.5-5 mg PO	No
Any	Serious or life threatening	Hold	10 mg IV† and repeat PRN	Yes

*1-2.5 mg PO for patients at increased risk for bleeding.
†Intravenous (IV) infusion should be given slowly.
FFP = fresh-frozen plasma; INR = international normalized ratio; PCC = prothrombin complex concentrate; PO = orally; PRN = as needed; rFVIIa, recombinant factor VIIa.

The INR is then performed two or three times weekly for 1 to 2 weeks and then weekly up to a maximal interval of 4 weeks, depending on the stability of INR results, and more frequently when a new drug is added to the treatment. Once the dose is stable, warfarin assessment up to every 12 weeks appears as safe and effective as every 4 weeks.[■■]

Adjustments to the dose when the INR drifts out of the therapeutic range should be gradual and based on the weekly dose (e.g., 10 to 20% changes in weekly dose). Patients should be encouraged to keep a log of their dose and their INR response.

Adverse Effects

Warfarin-related bleeding is increased by the level of the INR. The risk for bleeding is also increased with concomitant aspirin use, in persons older than 65 years, in those with a history of stroke or gastrointestinal bleeding, and in those with serious comorbid conditions. Elderly patients are more sensitive to warfarin, requiring lower doses to reach the therapeutic range, and have an increased tendency to bleed, including intracranially, even when their INR is in the therapeutic range (Chapter 24).

Warfarin-induced skin necrosis (Fig. 176-1) occurs in 1 in 5000 patients, more frequently in women, and affects mainly breasts, buttocks, and thighs. An imbalance between moderately reduced procoagulant factors and severely depressed natural inhibitors may cause this hypercoagulable state in patients with congenital deficiency of protein C or protein S (Chapter 176), dietary deficiency of vitamin K, cancer, or heparin-induced thrombocytopenia with premature start of vitamin K antagonists (Chapter 172).

Reversing the Effect of Warfarin

The anticoagulant effect of warfarin can be reversed in one of three ways: by discontinuation of therapy, with the expectation that the INR will return to baseline in about 5 days; by administration of vitamin K_1, with the expectation that the anticoagulant effect will be reduced in 6 hours and reversed in 24 hours; and by infusion of fresh-frozen plasma (FFP), prothrombin complex concentrate (PCC), or recombinant coagulation factor VIIa (rFVIIa), which produce immediate reversal (Table 38-1).

Heparin and Low-Molecular-Weight Heparins

Heparin

Heparin binds to antithrombin (AT), thereby increasing the rate at which AT inactivates thrombin, activated factor X (factor Xa), and other coagulation enzymes. Heparin accelerates the inactivation of thrombin by AT by providing a template to which both the enzyme and the inhibitor bind to form a ternary complex (Fig. 38-2). In contrast, the inactivation of factor Xa by the AT-heparin complex does not require ternary complex formation and is achieved by binding of the heparin-bound AT to factor Xa. Heparin binds to a number of plasma, platelet, and endothelial cell–derived proteins that compete with AT for heparin binding. Binding of heparin to plasma proteins contributes to the variability of its anticoagulant response, whereas binding to hepatic macrophages is responsible for its dose-dependent clearance. Both properties contribute to the unpredictable anticoagulant effect of heparin and the need for laboratory monitoring. The plasma half-life is about 60 minutes at therapeutic concentrations.

Heparin is effective for the prevention and treatment of VTE,[■] for the early treatment of patients with unstable angina and acute myocardial infarction,[■] for patients who have cardiac surgery under cardiopulmonary bypass,

for patients undergoing vascular surgery, and during and after coronary angioplasty and coronary stent placement.

The anticoagulant effects of heparin are usually monitored by the activated partial thromboplastin time (aPTT). A therapeutic effect is achieved when the aPTT ratio is equivalent to a heparin level of 0.3 to 0.7 anti–factor Xa units, which for many reagents is an aPTT ratio of 1.5 to 2.5. The risk for bleeding complications is increased with increasing heparin dosage, which in turn is related to the anticoagulant response. However, other clinical factors, such as recent surgery, trauma, and invasive procedures, are also important as predictors of bleeding during heparin treatment.

For the treatment of VTE, heparin is given in doses of 80 U/kg followed by 18 U/kg per hour by continuous infusion; the dose is adjusted according to the aPTT result at 6 hours by use of a validated nomogram. Lower doses (70 U/kg or 5000 U followed by 15 U/kg/h or 1000 U/hour) of heparin are used in patients with acute myocardial ischemia, who also receive aspirin and platelet glycoprotein IIb/IIIa complex (GPIIb-IIIa) antagonists or thrombolytic therapy.

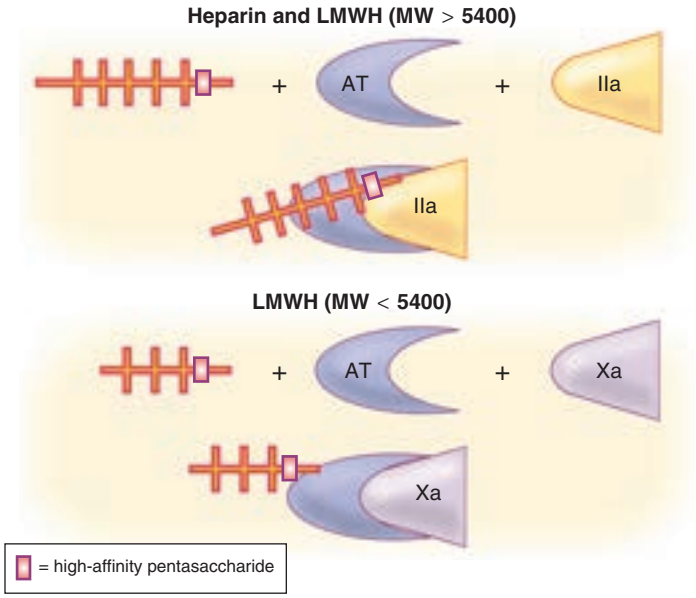

FIGURE 38-2. Only one third of high-affinity pentasaccharide-containing heparin molecules and one fifth of pentasaccharide-containing low-molecular-weight heparin (LMWH) molecules activate antithrombin (AT). Virtually all of the high-affinity heparin molecules are large enough to bridge between AT and factor IIa (thrombin). In contrast, only 25 to 50% of LMWH molecules have a molecular weight (MW) of 5400 or more, and although these smaller molecules inactivate factor Xa, they do not inactivate factor IIa. Although heparin has equal anti–factor IIa and anti–factor Xa activities, LMWH has reduced anti–factor IIa activity.

The main complications of heparin are bleeding and heparin-induced thrombocytopenia. Less common complications are heparin-induced osteoporosis and hyperkalemia. Heparin-related bleeding is dose related, and the risk is increased in patients who undergo an invasive procedure and if heparin is used in combination with a platelet GPIIb-IIIa antagonist or a thrombolytic agent.

If heparin-induced thrombocytopenia (Chapter 172) is suspected on clinical grounds and anticoagulant treatment is indicated, heparin should be stopped and replaced with a thrombin inhibitor: hirudin (lepirudin), argatroban, or danaparoid. Warfarin should not be used alone to treat acute heparin-induced thrombocytopenia because it can aggravate the thrombotic process, but it is safe in combination with a thrombin inhibitor after the platelet count has risen above 100×10^9/L.

Low-Molecular-Weight Heparins

Low-molecular-weight heparins (LMWHs) are fragments produced by either chemical or enzymatic depolymerization of heparin. LMWHs are approximately one third the size of heparin (Table 38-2). Depolymerization of heparin changes the anticoagulant profile. As a result, LMWHs have less protein and cellular binding and, as a consequence, have a more predictable dose response, better bioavailability, and a longer plasma half-life than regular heparin. LMWHs can therefore be administered subcutaneously once daily without laboratory monitoring.

Compared with heparin, which has a ratio of anti–factor Xa to anti–factor IIa activity of approximately 1 : 1, the various commercial LMWHs have ratios of anti–factor Xa to anti–factor IIa varying between 4 : 1 and 2 : 1, depending on their molecular size distribution. LMWHs are cleared principally by the renal route. They are associated with a lower incidence of heparin-induced thrombocytopenia and heparin-induced osteoporosis than is heparin.

LMWHs are effective in the prevention and treatment of VTE (Chapter 81),■ in the treatment of patients with unstable angina and non–ST elevation myocardial infarction (Chapters 72 and 73),■ and as an adjunct to fibrinolytic therapy in patients with acute ST elevation myocardial infarction (Chapter 73).

Pentasaccharides

On the basis of knowledge of the AT-binding sequence on heparin, a pentasaccharide, fondaparinux, with high affinity for AT has been synthesized. The structure of fondaparinux has been modified to increase its affinity to AT. Fondaparinux inactivates factor Xa through an AT-mediated mechanism. Because it is too short to bridge AT to thrombin, fondaparinux has no activity against thrombin.

After subcutaneous injection, fondaparinux is rapidly and completely absorbed and exhibits a bioavailability of 100%. The volume of distribution is similar to the blood volume. The drug is mainly excreted unchanged in the urine, with a terminal half-life of 17 hours in young volunteers and 21 hours in elderly volunteers.

TABLE 38-2 ANTICOAGULANT PROFILES, MOLECULAR WEIGHTS, PLASMA HALF-LIVES, AND RECOMMENDED DOSES OF COMMERCIAL LOW-MOLECULAR-WEIGHT HEPARINS AND HEPARINOID

AGENT	ANTI-X_a/ANTI-II_a RATIO	MOLECULAR WEIGHT	PLASMA HALF-LIFE (min)	*RECOMMENDED DOSE (INTERNATIONAL ANTI-XA UNITS)*		
				General Surgery Prophylaxis	*Orthopedic Surgery Prophylaxis*	ACUTE TREATMENT
Enoxaparin	2.7 : 1	4500	129-180	4000 U SC daily	4000 U SC daily or 3000 U SC bid	7000 U SC bid*† or 10,500 U SC daily*
Dalteparin	2 : 1	5000	119-139	2500 U SC daily	2500 U SC bid or 5000 U SC daily	8400 U SC bid*† or 14,000 U SC daily*
Nadroparin	3.2 : 1	4500	132-162	2850 U SC daily	2700 U SC daily,* 4000 U SC daily* from day 4	13,300 U SC daily*
Tinzaparin	1.9 : 1	4500	111	3500 U SC daily	3500 U SC daily* or 4500 U SC daily*	12,250 U daily*
Ardeparin	2 : 1	6000	200		50 U/kg SC bid	
Danaparoid‡	20 : 1	6500	1100	750 U SC daily	750 U SC bid	2500 U IV, then 4 hr each of 400 U/hr and 300 U/hr, then 200 U/hr; or 2000 U SC bid

*Weight-adjusted dose; stated dose for 70-kg patient.
†The higher daily dose is for acute coronary syndromes; the lower dose is for deep vein thrombosis.
‡Danaparoid sodium is a heparinoid.
IV = intravenously; SC = subcutaneously.

Fondaparinux circulates extensively bound to AT with minimal binding to other plasma proteins. Limited experimental and clinical studies suggest that fondaparinux has a lower risk for heparin-induced thrombocytopenia than that of heparin or LMWH as well as a lower risk for bone loss and of local skin reactions.

Fondaparinux is effective in the prevention and treatment of VTE and is also effective and safe in the treatment of acute coronary syndromes.

New Anticoagulants

The limitations of established anticoagulants have prompted the development of a variety of new anticoagulant agents that target various specific steps in the coagulation mechanism.[1,2]

Direct Thrombin Inhibitors

Direct thrombin inhibitors act independently of AT to inactivate both free thrombin and thrombin bound to fibrin. The direct thrombin inhibitors include hirudin, synthetic hirudin fragments (hirugen, lepirudin, and bivalirudin [Hirulog]), and low-molecular-weight inhibitors that react with the active site of thrombin (dabigatran and argatroban).[3]

Bivalirudin is approved for use in coronary angioplasty (Chapter 73) and reduces the risk for major bleeding in comparison with heparin. Argatroban and lepirudin are approved in patients with heparin-induced thrombocytopenia (Chapter 172). Data comparing argatroban with hirudin in heparin-induced thrombocytopenia are too limited for conclusions to be drawn about their relative efficacy and safety. Argatroban is metabolized in the liver and can be used in patients with renal failure, whereas the other direct thrombin inhibitors depend on elimination through renal excretion, and they may be used in patients with liver disease.

Dabigatran etexilate is administered orally and metabolized by ubiquitous esterases to dabigatran, a reversible, active-site thrombin inhibitor. The pharmacokinetic characteristics of dabigatran and the oral factor Xa inhibitors are summarized in Table 38-3. Dabigatran etexilate has been approved in Europe and several other countries for prophylaxis against VTE after hip or knee arthroplasty (first dose, 110 mg; then 220 mg once daily; for patients older than 70 years or with creatinine clearance of 30 to 50 mL/minute, first dose 75 mg and then 150 mg daily). The effect is similar to that of enoxaparin (40 mg subcutaneously daily). Dabigatran (150 mg twice daily) is more effective than warfarin for stroke prophylaxis in atrial fibrillation, whereas a lower dose (110 mg twice daily) is equally effective with lower risk for major bleeding. Both doses resulted in fewer intracranial hemorrhages than warfarin. The 110-mg regimen has not been approved in the United States, but for patients with a calculated creatinine clearance of 15 to 30 mL/minute, the dose of 75 mg twice daily is available. In the treatment of VTE, dabigatran (150 mg twice daily) has comparable effect to warfarin and is at least as safe regarding bleeding. In terms of periprocedural bleeding, dabigatran and warfarin are equivalently safe, and dabigatran facilitates a shorter interruption of oral anticoagulation.

Direct Factor Xa Inhibitors

A number of orally available low-molecular-weight active site-directed factor Xa inhibitors have been designed and are in various stages of clinical development (rivaroxaban, apixaban, betrixaban, edoxaban). Unlike heparins and pentasaccharide, direct inhibitors inactivate factor Xa without the need for AT as a cofactor.

Rivaroxaban, an oxazolidinone derivative (10 mg daily for 30 to 39 days), is more effective than enoxaparin in patients undergoing hip or knee arthroplasty but with a trend to more bleeding. For stroke prophylaxis in atrial fibrillation, rivaroxaban when compared with warfarin showed similar efficacy and safety. In patients with acute coronary syndromes, rivaroxaban, when added to standard antiplatelet therapy, reduced the risk for thromboembolic events at the cost of increased bleeding. In the treatment of VTE, rivaroxaban had similar efficacy to vitamin K antagonists, and in the trial with patients with pulmonary embolism, rivaroxaban reduced the risk for major bleeding.

Apixaban (2.5 mg twice daily) for prophylaxis against VTE after hip or knee arthroplasty has similar or better efficacy than LMWH and similar or lower risk for bleeding. In atrial fibrillation, apixaban (5 mg twice daily) reduces the risk for stroke and for major bleeding compared with warfarin, and it reduces the risk for stroke without any increase of major bleeding in comparison with aspirin. For patients with VTE, apixaban (5 mg twice daily) has similar effect as warfarin but with a reduced risk for major bleeding.

Edoxaban (60 mg daily after initial LMWH) for patients with VTE has similar effect and risk for major bleeding as warfarin. For patients with extensive pulmonary embolism, edoxaban appears to be more effective than warfarin. For patients with atrial fibrillation, edoxaban (60 mg daily) has similar risk for stroke and lower risk for major bleeding compared with warfarin.

All four new anticoagulants have in common that they were associated with a relative risk reduction for death by 10% and for intracranial hemorrhage by approximately 50% compared with warfarin (Table 38-4). In the 2012 ACCP practice guidelines, only dabigatran received a grade A recommendation because there were not sufficient data available for the other anticoagulants. It is, however, difficult to claim that one drug is better than the other based solely on indirect comparisons. A recent review of the combined results of phase 3 trials comparing direct oral anticoagulants (dabigatran, rivaroxaban, apixaban, or edoxaban) with vitamin K antagonists in the treatment of patients with acute symptomatic VTE concluded that direct oral anticoagulants have similar efficacy but significantly reduce the risks of major bleeding compared with vitamin K antagonists. None of the new oral anticoagulants have, however, demonstrated equivalent or superior efficacy and safety compared with traditional anticoagulants in thromboprophylaxis for patients with mechanical heart valves, and therefore their use in this setting is not recommended at this time.

Platelet-Active Drugs

The platelet-active drugs inhibit different steps in either platelet activation (aspirin, ticlopidine, clopidogrel, prasugrel, ticagrelor, cilostazol, and dipyridamole) or platelet recruitment (GPIIb-IIIa antagonists abciximab, tirofiban, and eptifibatide) (Fig. 38-3).

Aspirin and Other Cyclooxygenase Inhibitors

Mechanism of Action and Pharmacology

Aspirin permanently inactivates cyclooxygenase isoenzymes (COX-1 and COX-2) that catalyze the conversion of arachidonic acid to prostaglandin H_2, a precursor of a variety of eicosanoids, including thromboxane A_2 in platelets and prostacyclin (prostaglandin I_2) in vascular endothelial cells (Chapter 37).

Aspirin is rapidly absorbed in the stomach and upper intestine, attaining peak plasma levels about 30 minutes after ingestion; it has a half-life of about 15 minutes. Inhibition of platelet function is evident by 1 hour with uncoated aspirin but can be delayed after administration of enteric-coated aspirin. Therefore, if only enteric-coated tablets are available when a rapid effect is required, the tablets should be chewed.

Aspirin potentiates the antithrombotic effects of warfarin (in high-risk subjects), dipyridamole (in those with ischemic stroke), clopidogrel (in those

with coronary stents or acute myocardial ischemia), and heparin (in the prevention of recurrent miscarriages in pregnant women with antiphospholipid antibody syndrome and in patients with acute coronary ischemia). Aspirin produces a small increase in major bleeding and a very small increase in the risk for cerebral hemorrhage. It also potentiates bleeding when it is added to another antithrombotic agent.

Aspirin causes gastrointestinal side effects that are dose dependent. Aspirin is contraindicated in individuals with active peptic ulcer disease or aspirin-induced asthma or if gastrointestinal side effects are severe.

Clinical Uses

Based on the results of a meta-analysis, there is evidence that aspirin reduces vascular death by approximately 15% and nonfatal vascular events by about 30% in patients with cardiovascular disease.[■] These effects are achieved in patients with silent myocardial ischemia or stable angina,[■] unstable angina,[■] non–ST elevation myocardial infarction,[■] ST elevation myocardial infarction,[■] noncardioembolic ischemic cerebrovascular disease,[■] and peripheral arterial disease.[■] Aspirin is also effective in patients after coronary angioplasty,[■] coronary[■] or peripheral artery stenting,[■] angioplasty,[■] or bypass graft,[■] symptomatic carotid artery stenosis,[■] or for 1 year after coronary artery bypass surgery[■] and in preventing symptomatic coronary events in asymptomatic men and women older than 50 years.[■] Aspirin has a favorable risk-to-benefit ratio for secondary prevention in patients with overt vascular disease, but the risk-to-benefit ratio is marginal when aspirin is used as primary prevention in asymptomatic individuals, even individuals with type 2 diabetes. Aspirin is less effective than oral anticoagulants in the prevention of recurrent stroke in atrial fibrillation.

Phosphodiesterase Inhibitors

Dipyridamole and cilostazol are phosphodiesterase inhibitors, which elevate platelet cyclic adenosine and guanine monophosphate (cAMP and cGMP) levels. They block platelet reactivity and also inhibit vasoconstriction. The most common side effect is headache.

Dipyridamole is a pyrimidopyrimidine derivative with a terminal half-life of 10 hours and elimination primarily by biliary excretion. Favorable results were obtained with a modified-release preparation in combination with aspirin in patients with carotid stenosis[■] and in patients with prior noncardioembolic stroke or transient ischemic attack,[■] in whom the risk for stroke was reduced by 16% with dipyridamole alone and by 37% with aspirin and dipyridamole in combination, compared with placebo.

In a meta-analysis, cilostazol (100 mg twice daily) was shown to reduce vascular events, driven by fewer cerebrovascular events,[■] and in another meta-analysis to improve maximal and pain-free walking distance in patients with intermittent claudication.[■] Cilostazol is contraindicated in patients with congestive heart failure, owing to reports of fatal events with similar drugs.

Thienopyridines

Ticlopidine, clopidogrel, and prasugrel are thienopyridines that inhibit adenosine diphosphate–induced platelet aggregation through the action of their active metabolites at the $P2Y_{12}$ receptor level. The drugs are administered orally, but their onset of action is delayed until their active metabolites are formed. Similarly, recovery of platelet function is delayed until the circulating affected platelets are replaced by newly formed, unaffected platelets.

Based on a better safety profile and equal efficacy, clopidogrel has replaced ticlopidine. Clopidogrel is rapidly absorbed and metabolized, producing inhibition of platelet aggregation as soon as 90 minutes after an oral loading dosing of 300 mg. With repeated daily administration of low doses (75 mg), there is cumulative inhibition of platelet function with a return to normal 7 days after the last dose of clopidogrel.

Clopidogrel is marginally more effective than aspirin in patients who have experienced a recent stroke[■] or recent myocardial infarction[■] and in patients presenting with symptomatic peripheral arterial disease.[■] The additional benefit over aspirin is modest and similar to that observed with ticlopidine (about 10% relative risk reduction). Clopidogrel is also recommended for patients with symptomatic carotid artery stenosis[■] or peripheral artery angioplasty.[■] The combination of clopidogrel and aspirin is also more effective than aspirin alone in patients with unstable angina and non–ST elevation myocardial infarction (20% risk reduction) and in patients with atrial fibrillation, but at a cost of a modest increase in bleeding. The combination of clopidogrel and aspirin is also more effective than aspirin alone in patients who have percutaneous coronary intervention procedures and is recommended for 1 month after insertion of a bare metal stent, and for 3 to 6 months after a drug eluting stent.[■] Clopidogrel appears to be as well tolerated as aspirin.

Prasugrel is more potent and has a more rapid onset of action than clopidogrel. Given as a bolus dose of 60 mg, followed by 10 mg daily, when compared with clopidogrel, prasugrel reduces the absolute risk for cardiovascular death or nonfatal myocardial infarction or stroke by 2.2%, which is partly offset by an absolute increase of serious bleeding of 0.5%.

Ticagrelor, an oral direct and reversible $P2Y_{12}$ receptor inhibitor, provides a faster response than the thienopyridines. In a randomized trial in patients with acute coronary syndromes, ticagrelor was more effective than clopidogrel, providing an absolute risk reduction for cardiovascular death, myocardial infarction, or stroke of 1.9% without any significant increase of major bleeding.

Integrin $\alpha_{IIb}\beta_3$ (GPIIb-IIIa) Receptor Antagonists

The final common pathway of platelet aggregation is mediated by the binding of fibrinogen to the functionally active integrin $\alpha_{IIb}\beta_3$ (GPIIb-IIIa) on the platelet surface. Inhibitors of this process include monoclonal antibodies, synthetic peptides containing Arg-Gly-Asp (RGD) or Lys-Gly-Asp (KGD), and peptidomimetic and nonpeptide RGD mimetics. These compounds are administered intravenously, and they inhibit platelet function by competing with fibrinogen (and von Willebrand factor) for occupancy on the platelet integrin receptor. Abciximab (ReoPro), a mouse-human chimeric 7E3 Fab antibody, inhibits platelet aggregation in a concentration-dependent manner. Platelet function is impaired rapidly after an intravenous bolus of abciximab and gradually recovers over 24 to 48 hours. Tirofiban (MK-383, Aggrastat) is a nonpeptide derivative of tyrosine. It has a plasma half-life of 1.6 hours, and its effect on hemostasis is reversed within 4 hours of stopping treatment. Eptifibatide (Integrilin) is a synthetic disulfide-linked cyclic heptapeptide. It has a rapid onset and offset of action, and its effect on platelet function is reduced by more than 50% after 4 hours.

All three GPIIb-IIIa receptor antagonists are effective intravenous agents in patients undergoing percutaneous coronary interventions (Chapter 74), and tirofiban and eptifibatide are effective in patients with unstable angina or non–ST elevation myocardial infarction. The GPIIb-IIIa receptor antagonists are administered in combination with heparin and aspirin. Orally active nonpeptide GPIIb-IIIa inhibitors have been developed for long-term use, but the results of clinical trials have been disappointing.

Fibrinolytic Agents

Fibrinolytic agents convert plasminogen to the enzyme plasmin, which then degrades fibrin to soluble fragments, thereby lysing the thrombus. Of the available fibrinolytic agents, streptokinase and urokinase are not fibrin specific; in contrast, recombinant tissue-type plasminogen activator (rt-PA, alteplase) and the rt-PA variant tenecteplase are relatively fibrin specific (Chapter 73).

Streptokinase is an indirect fibrinolytic agent. It binds to plasminogen, converting it into a plasmin-like molecule that in turn converts plasminogen to plasmin. Streptokinase has a number of disadvantages. It is antigenic, rendering its repeated use problematic, and allergenic, producing chills, fever, and rigors in some patients and, in rare instances, anaphylaxis. Anistreplase (APSAC) is an acylated complex of streptokinase and Lys-plasminogen. Compared with streptokinase, it is more fibrin specific, has a longer plasma half-life, and is inactive until it is selectively activated by deacylation on the fibrin surface. Its side-effect profile, antigenicity, and efficacy are similar to those of streptokinase.

Urokinase is a naturally occurring plasminogen activator that differs from streptokinase in that it directly activates plasminogen and is not antigenic. Urokinase was used extensively to treat peripheral vascular occlusions, but production problems have curtailed its availability.

In its natural state, tissue plasminogen activator is produced by vascular endothelium; rt-PA (alteplase) is produced by recombinant DNA technology. Alteplase is not antigenic or allergenic, and it has greater fibrin specificity than streptokinase. It has a short half-life of about 3.5 minutes and therefore is given as a continuous intravenous infusion.

Truncated forms of rt-PA have been developed; the first was reteplase (r-PA), a single-chain deletion mutant that lacks certain domains. As a result, its half-life is about twice that of rt-PA, permitting double-bolus therapy 30 minutes apart. r-PA has lower affinity for fibrin than does rt-PA, but fibrinogen depletion with r-PA is less than that with streptokinase. No antigenicity has been reported with this compound.

Tenecteplase (TNK-tPA) is a mutant tissue plasminogen activator with amino acid substitution at three sites. Compared with rt-PA, it has a longer half-life, allowing single-bolus administration, increased fibrin specificity, and increased resistance to inhibition by plasminogen activator inhibitor 1.

Clinical Uses

Thrombolytic therapy reduces mortality in patients with ST-elevation myocardial infarction and for whom primary percutaneous coronary intervention is unavailable, as well as in patients with extensive pulmonary embolism and hypotension. Treatment with rt-PA intravenously within 3 hours from onset of symptoms of ischemic stroke increases the likelihood of good functional outcome despite a small increase in the risk for intracerebral hemorrhage. Thrombolysis can be justified for severe pulmonary embolism without contraindications, but thrombolysis in patients with moderate-risk pulmonary embolism does not improve outcomes despite better hemodynamics, because of increases in major bleeding and stroke.

SUMMARY OF GRADE A RECOMMENDATIONS FOR ANTITHROMBOTIC THERAPY

Grade 1A indicates that experts are certain that benefits do or do not outweigh risks, burdens, and costs. The reduction in number of grade A recommendations compared with previous editions is due to several changes in the development of the American College of Chest Physicians (ACCP) guidelines. In particular, (a) the GRADE methodology was strictly adhered to, (b) much less importance was paid to surrogate outcomes, and (c) intellectual conflicts were taken into account. Recommendations for the Prevention and Treatment of Venous Thromboembolic Disease that were not considered grade 1A are cited in the General References.[4-9]

ATRIAL FIBRILLATION, INCLUDING PAROXYSMAL (CHAPTER 64)

Patients with Previous Ischemic Stroke, Transient Ischemic Attack (TIA) or At Least Two Other Risk Factors For Stroke

- Standard approach: oral anticoagulation with dabigatran, 150 mg twice daily, or warfarin (INR range, 2.0-3.0) (grade 1A)

VALVULAR AND STRUCTURAL HEART DISEASE (CHAPTER 75)

Mitral Valve Disease

- Rheumatic mitral valve disease with atrial fibrillation, previous systemic embolism, or left atrial thrombus: warfarin anticoagulation (INR range, 2.0-3.0) (grade 1A)
- Mitral stenosis with left atrial thrombus before percutaneous mitral balloon valvotomy: warfarin anticoagulation (INR range, 2.0-3.0) until thrombus resolution is documented (grade 1A)

ANTITHROMBOTIC AND THROMBOLYTIC THERAPY FOR ISCHEMIC STROKE (CHAPTER 407)

- Acute ischemic stroke treatment within 3 hours of onset of symptoms, in eligible patients: thrombolytic therapy with IV rt-PA in a dose of 0.9 mg/kg (maximum of 90 mg), with 10% of the total dose given as an initial bolus and the remainder infused during 60 minutes (grade 1A)
- Acute ischemic stroke or TIA within 48 hours: aspirin in a dose of 160 to 325 mg once daily (grade 1A)
- Noncardioembolic ischemic stroke or TIA: long-term treatment with aspirin, 75 to 100 mg once daily, or clopidogrel, 75 mg once daily; or a combination of aspirin and extended-release dipyridamole, 25 mg/200 mg twice daily, or cilostazol, 100 mg twice daily (grade 1A)
- Cryptogenic stroke and patent foramen ovale or atrial septal aneurysm: long-term treatment with aspirin 50 to 100 mg once daily (grade 1A)
- Ischemic stroke or TIA and atrial fibrillation, including paroxysmal: long-term oral anticoagulation with dabigatran, 150 mg twice daily, or warfarin (INR range, 2.0-3.0) (grade 1A)

CORONARY ARTERY DISEASE (CHAPTER 72, 73, 74)

- Established coronary artery disease, including coronary artery stenoses >50% by coronary angiogram, cardiac ischemia on diagnostic testing, 1 year after acute coronary syndrome or after coronary artery bypass graft: long-term aspirin, 75 to 100 mg daily, or clopidogrel, 75 mg daily (grade 1A)
- Elective percutaneous coronary intervention with placement of bare metal stent: dual antiplatelet therapy for 1 month with aspirin, 75 to 325 mg daily, and clopidogrel, 75 mg daily (grade 1A)
- Elective percutaneous coronary intervention with placement of drug eluting stent: dual antiplatelet therapy for 3 to 6 months with aspirin, 75 to 325 mg daily, and clopidogrel, 75 mg daily (grade 1A)

PERIPHERAL ARTERIAL DISEASE (CHAPTER 79)

- Symptomatic peripheral arterial disease: long-term aspirin, 75 to 100 mg daily, or clopidogrel, 75 mg daily (grade 1A)
- Peripheral artery percutaneous transluminal angioplasty with or without stenting: long-term aspirin, 75 to 100 mg daily, or clopidogrel 75 mg daily (grade 1A)
- Peripheral artery bypass graft surgery: long-term aspirin, 75 to 100 mg daily, or clopidogrel, 75 mg daily (grade 1A)
- Symptomatic carotid artery stenosis, including recent carotid endarterectomy: long-term aspirin, 75 to 100 mg daily, or clopidogrel, 75 mg daily, or aspirin with extended-release dipyridamole, 25 mg/200 mg twice daily (grade 1A)

REVIEW QUESTIONS

1. Based on the half-life and onset of action of warfarin, which of the following is the optimal management of this drug in the case of uncomplicated major surgery?

A. Warfarin should be stopped 5 days before surgery and restarted as soon as the patient can take oral medications after surgery.
B. Warfarin should be stopped 2 days before surgery and restarted as soon as the patient can take oral medications after surgery.
C. Warfarin should be stopped 5 days before surgery and restarted at least 5 days after surgery.
D. Warfarin should be stopped 2 days before surgery and restarted at least 5 days after surgery.

Answer: A With a half-life of 40 hours, warfarin has to be stopped 5 days before surgery to eliminate the anticoagulant effect. It takes 5 to 7 days for warfarin to achieve therapeutic anticoagulant effect, and thus it can be started very shortly after surgery provided that there is no bowel paralysis or active bleeding. (Douketis JD, Spyropoulos AC, Spencer FA, et al. *Chest.* 2012;141:e326S-e350S.)

2. For a patient requiring treatment for pulmonary embolism but with a high risk for bleeding, for whom quick elimination of the anticoagulant effect is desirable, which one of the heparins is preferable?

A. Unfractionated heparin (as intravenous infusion)
B. Fondaparinux
C. Danaparoid
D. Low-molecular-weight heparin

Answer: A With a half-life of 1 hour at therapeutic concentration, unfractionated heparin is the heparin that will be eliminated fastest. Low-molecular-weight heparins have half-lives of 2 to 3 hours, and fondaparinux and danaparoid about 20 hours.

3. For which one of the new oral anticoagulants would screening with a thrombin time analysis be sensitive to identify clinically important plasma concentrations of the drug?

A. Dabigatran
B. Rivaroxaban
C. Apixaban
D. Edoxaban
E. Argatroban

Answer: A Dabigatran and argatroban are direct thrombin inhibitors, for which a thrombin time is a sensitive test, but argatroban is not an orally available drug. The others are factor Xa inhibitors, for which thrombin time is less sensitive.

4. Which combinations of antiplatelet therapy are recommended because they provide better effect than single-antiplatelet therapy?

A. Aspirin + dipyridamole in noncardioembolic stroke and aspirin + clopidogrel in unstable angina/non–ST elevation myocardial infarction.
B. Aspirin + clopidogrel in noncardioembolic stroke and ticagrelor + clopidogrel in unstable angina/non–ST elevation myocardial infarction.
C. Aspirin + dipyridamole in noncardioembolic stroke and aspirin + clopidogrel in peripheral arterial disease.
D. Aspirin + dipyridamole in peripheral arterial disease and aspirin + ticagrelor in unstable angina/non–ST elevation myocardial infarction.
E. Aspirin + clopidogrel in peripheral arterial disease and aspirin + dipyridamole in cardioembolic stroke.

Answer: A In noncardioembolic stroke, aspirin plus dipyridamole provides a 37% reduction of recurrent stroke compared with 16% with dipyridamole alone. In unstable angina and non–ST elevation myocardial infarction, the combination of aspirin plus clopidogrel provides 20% greater risk reduction than aspirin alone.

5. What is the objective of thrombolytic therapy in patients with acute ischemic stroke (treatment within 3 hours from onset of symptoms)?

A. To improve the functional outcome
B. To reduce mortality
C. To reduce cardiovascular death
D. To eliminate the need for anticoagulation
E. To shorten the duration of hospitalization

Answer: A Treatment with tissue plasminogen activator within 3 hours of ischemic stroke is associated with a significant increase in the proportion of patients with good functional outcome. Even if duration of hospitalization may thereby be shortened, this is not the objective of the treatment. Thrombolysis does not reduce mortality and does not eliminate the need for ensuing anticoagulation in case of cardioembolic stroke.

COMPLEMENTARY AND ALTERNATIVE MEDICINE

ADAM PERLMAN

The National Institutes of Health's National Center for Complementary and Alternative Medicine (NCCAM) has defined complementary and alternative medicine (CAM) as " a group of diverse medical and health care systems, practices, and products that are not generally considered to be part of conventional medicine." The use of CAM by the general public has continued to grow. In the United States, approximately 12% of children and 38% of adults are using some form of CAM, and when the use of megavitamins as well as the use of prayer specifically for health reasons is added, the number increases to 62%. Use of CAM is higher in women and those with more education, but CAM use cuts across all socioeconomic levels, races, and ethnicities. In certain populations, such as patients with cancer or rheumatologic conditions, use of CAM can be significantly higher. In one study, 75% of cancer patients surveyed had used at least one CAM modality, and 58% of those using CAM initiated use after they were diagnosed.[1]

Perhaps motivated by growing patient interest in an era of increased consumerism in health care or frustration with the current evolution of health care, many conventional providers have developed interest and expertise in the integration of CAM into patient care. However, it is important to differentiate between integrating CAM and another growing field within health care, integrative medicine. Integrative medicine has been defined as "an approach to care that puts the patient at the center and addresses the full range of physical, emotional, mental, social, spiritual, and environmental influences that affect a person's health. Employing a personalized strategy that considers the patient's unique conditions, needs, and circumstances, it uses the most appropriate interventions from an array of scientific disciplines to heal illness and disease and help people regain and maintain optimum health."[2] Integrative medicine and integrative medicine programs are increasingly prevalent within the academic medical community. Formed in 1999, the Consortium of Academic Health Centers for Integrative Medicine now includes more than one third of all Academic Health Centers in North America.

Many of the principles as defined in Table 39-1 are not unique to integrative medicine, and interest in them has been increasing as a part of the evolving transformation of the U.S. health care system. This has led to a growing interest in integrative medicine as well as CAM and the need for physicians and all health care providers to have, at a minimum, a basic understanding of CAM. Health care providers must be comfortable engaging in a dialogue with patients about their potential use of CAM and the evidence base or lack thereof for the more popular CAM modalities as well as any potential safety concerns.

Most recently, NCCAM has used the term *complementary health approaches* to describe the practices and products that are studied as a part of NCCAM's research portfolio. In general, that portfolio can be separated into two main subgroups: natural products and mind and body practices.

NATURAL PRODUCTS

Natural products, often referred to as dietary supplements, include vitamins and minerals, herbs or botanicals, and a category referred to as nonvitamin, nonmineral natural products. After prayer, use of natural products was the most common complementary health approach among adults surveyed in 2007, with 17.7% of adults having reported using natural products during the previous 12 months. The 2007 National Health Interview Survey (NHIS) also revealed that 83 million U.S. adults spent almost $44 billion dollars out of pocket on visits to CAM practitioners and purchases of CAM products, classes, or materials. Of that out-of-pocked spending, $14.8 billion, or 43.7%, was for nonvitamin, nonmineral natural products (Table 39-2).

Commonly used natural products in adults include such substances as fish oil, glucosamine, and probiotics, and in children, fish oil, probiotics, and Echinacea. There is a growing body of research literature on numerous natural products with mixed conclusions regarding efficacy. As with any substance that has a physiologic effect on the body, many natural products, although typically safe, do have the potential for side effects as well as the potential to interact with medication. Many commonly used dietary supplements, such vitamin E, Ginkgo, and fish oil, can affect platelet function and therefore lead to an increased risk for bleeding. Patients are often unaware of these potential side effects or interactions with medications.

Currently, natural products are regulated under the Dietary Supplement Health and Education Act (DSHEA). Enacted by Congress in 1994, this act gives the U.S. Food and Drug Administration (FDA) the power to regulate both finished dietary supplement products and dietary ingredients. Dietary supplements are defined as products (other than tobacco) that are intended to supplement the diet and include one or more of the following ingredients: a vitamin, a mineral, an herb or other botanical, an amino acid, a substance for use by humans to supplement the diet by increasing the total dietary intake; or a concentrate, metabolite, constituent, extract, or combination of any of the aforementioned ingredients.

Manufacturers are responsible for ensuring that products are safe before bringing them to market, and the FDA is responsible for taking action against any unsafe product after it has reached the market. Although the FDA has a system in effect for the collection and review of adverse effects linked to dietary supplements, that system is voluntary, and concerns have been raised that the agency does not have adequate resources to ensure safety of products currently on the market in a timely and effective way.

TABLE 39-1 DEFINING PRINCIPLES OF INTEGRATIVE MEDICINE

The defining principles of integrative medicine are as follow:

- The patient and practitioner are partners in the healing process.
- All factors that influence health, wellness, and disease are taken into consideration.
- The care addresses the whole person, including body, mind, and spirit in the context of community.
- Practitioners use all appropriate healing sciences to facilitate the body's innate healing response.
- Effective interventions that are natural and less invasive are used whenever possible.
- Because good medicine is based in good science, integrative medicine is inquiry driven and open to new models of care.
- Alongside the concept of treatment, the broader concepts of health promotion and the prevention of illness are paramount.
- Care is individualized to best address the person's unique conditions, needs, and circumstances.
- Practitioners of integrative medicine exemplify its principles and commit themselves to self-exploration and self-development.

Data from Horrigan, B, Lewis, S, Abrams D, et al. *Integrative Medicine in America: How Integrative Medicine Is Being Practiced in Clinical Centers across the United States*. Encinitas, CA: The Bravewell Collaborative; 2012.

TABLE 39-2 USE OF COMPLEMENTARY OR ALTERNATIVE MEDICINE BY U.S. ADULTS IN 2007

MODALITY	PERCENTAGE OF ADULTS WHO USED IT
BIOLOGICALLY BASED THERAPIES	
Herbal or natural products	17.7
Dietary supplements	N/A
Diet-based therapy	3.5
BODY-BASED PRACTICES	
Chiropractic or osteopathic manipulation	8.6
Massage	8.3
Movement therapies*	1.5
MIND-BODY THERAPIES	
Biofeedback	0.2
Hypnosis	0.2
Meditation	9.4
Guided imagery	2.2
Progressive relaxation	2.9
Deep breathing	12.7
Yoga	6.1
Tai chi	1.0
Qi gong	0.3
ENERGY MEDICINE†	
Reiki, biofield, and other therapies	0.5
WHOLE MEDICAL SYSTEMS	
Naturopathy	0.3
Homeopathy	1.8
Ayurveda	0.1
Traditional Chinese medicine (acupuncture)	1.4
Traditional healers	0.4

*Pilates, Trager, Feldenkrais, and Alexander.
†Energy medicine is based on the theory that there are energy fields surrounding and penetrating the human body. Energy therapies are intended to manipulate these energy fields.

DSHEA also allowed for the enactment of regulations to ensure that manufacturers follow good manufacturing practices. In addition, the act clarified which claims are permissible for dietary supplement labels. It does not allow claims that a dietary supplement will "diagnose, prevent, mitigate, treat, or cure a specific disease" but does allow assertions that a dietary ingredient will affect the structure or function of the body. The Federal Trade Commission has responsibility and authority to regulate advertising for dietary supplements.

DSHEA also established the Office of Dietary Supplements (ODS) at the National Institutes of Health. This Mission of ODS is to "strengthen knowledge and understanding of dietary supplements by evaluating scientific information, stimulating and supporting research, disseminating research results, and educating the public to foster an enhanced quality of life and health for the U.S. population."

MIND AND BODY PRACTICES

As defined by NCCAM, mind and body practices "include a diverse group of procedures or techniques administered or taught by a trained practitioner or teacher." Mind and body practices include such therapies as meditation, acupuncture, massage therapy, movement therapy, relaxation techniques, spinal manipulation, tai chi, yoga, and various energy therapies, such as healing touch, Reiki, or qi gong. Mind and body practices as defined by NCCAM should not be confused with the commonly used term *mind-body medicine*. Mind-body medicine is typically used to describe techniques that are specifically designed to enhance the mind's ability to cause physiologic effects that will lead a positive therapeutic outcome, such as decreased pain or anxiety.

Meditation

Meditation, which involves various techniques to self-regulate attention, has been used for thousands of years by various religions and cultures, primarily in Asia, to increase awareness and ultimately improve self-understanding, inner peace, and enlightenment. In Western culture, meditation has gained in popularity since the 1960s and is often used without a religious context to help manage stress and improve overall health.

The physiologic effect of meditation has been extensively studied. Meditation has been shown to increase activity of the autonomic nervous system and bring about what Benson has termed "the relaxation response."[3] This response can lead not only to the subjective sense of decreased stress but also to measurable effects such as a lowering of blood pressure and heart rate. Other investigators have found evidence of increased blood flow in the brain and altered brain chemistry (see Relaxation Techniques, later). Regular meditation is associated with increased α-wave activity as well as decreased levels of hormones associated with stress, such as cortisol and epinephrine, and increased levels of melatonin.

Many meditation techniques exist, and meditation can be taught in individual or group sessions. Meditation has been shown to have potential benefits for managing conditions such as stress, anxiety, cognitive function in elderly people, gastrointestinal disorders, chronic pain, addictions, and even psoriasis. Although some techniques, such as transcendental meditation, have been more extensively studied, evidence comparing the potential effectiveness of various techniques is largely lacking.

Although safe for most patients, limited evidence suggests that meditation should be approached cautiously for anyone at risk for seizures, symptomatic low blood pressure, or psychotic illness. In one small study of meditators involved in an intensive meditation retreat, more than half of the participants experienced at least one adverse effect.

Acupuncture

Practiced in China for more than 5000 years, acupuncture involves the insertion of very fine needles at specific points in the body. These approximately 360 acupoints reside along 14 channels in the body called *meridians*. In Chinese medical theory, the insertion of the needles is intended to stimulate or improve the balance of the flow of "life energy" or *qi* (pronounced chi). Symptoms or disease are thought to be related to a blockage of flow or imbalance of *qi*. Although very different from a Western medical view of pathophysiology, acupuncture has been shown to have various physiologic effects on the body, including stimulation of endorphins and various brain centers.

There is a growing body of research investigating the potential benefits of acupuncture for a number of conditions. To date, there is evidence suggesting that acupuncture may be beneficial for pain from conditions such as dental pain, fibromyalgia, and headache,[4] as well as beneficial in stroke, analgesia during childbirth, and infertility treatment. A meta-analysis suggests that stimulation of the P6 acupuncture point at the wrist is a potentially effective intervention for reducing postoperative nausea and vomiting.[5] Randomized trials evaluating acupuncture for osteoarthritis of the knee show conflicting results, in part depending on study design, but a recent carefully controlled, blinded trial showed no benefit.

It is important to explain to patients interested in a trying acupuncture, that the needles are typically ultra-fine and often not painful. An

acupuncturist's assessment of the patient will determine the exact location of the needles to be placed. Repeat treatment most commonly occurs once a week, and it often requires 8 to 10 treatments to assess whether acupuncture will have a therapeutic effect.

Modern acupuncture using primarily sterile, disposable needles is generally safe. Risk for infection, although rare, does exist, and electro-acupuncture, which involves stimulation of the acupuncture point by passing a very weak electrical current along the needle, should be avoided in patients with electronic implantable devices such as pacemakers.

Massage Therapy

Massage therapy is perhaps one of the oldest healing modalities. Hippocrates is quoted as saying "the physician must be experienced in many things, but most assuredly in rubbing." Massage is most commonly used to relieve pain from musculoskeletal and other conditions as well as to improve function or relieve stress and aid in relaxation. However, there are more than 80 different types of therapeutic massage, and certain techniques may be more beneficial than others for specific conditions or complaints. Massage has a high use and acceptability in the United States, with approximately 18 million U.S. adults receiving massage in 2007.

The exact mechanism by which massage may exert a therapeutic effect is not clear. Massage is reported to improve local circulation, tone of supportive musculature, and joint flexibility. One commonly held belief was that lactic acid build-up led to delayed-onset muscle soreness and that massage removed lactic acid from muscle. Lactic acid is only present substantially during and immediately after high-intensity anaerobic exercise. It is metabolized within 60 minutes after such exercise ceases and converted back to pyruvate for processing in the Krebs cycle to produce further energy. Some research has suggested that massage may impair lactic acid removal from muscle after strenuous exercise by mechanically impeding blood flow. One study found that massage appeared to exert a clinical benefit by reducing inflammation and promoting mitochondrial biogenesis.[6] In a study of 11 young male athletes, massage was found to activate the mechanotransduction signaling pathways, focal adhesion kinase (FAK) and extracellular signal–regulated kinase 1/2 (ERK1/2), potentiate mitochondrial biogenesis signaling (nuclear peroxisome proliferator–activated receptor γ coactivator 1α [PGC-1α]), and mitigate an increase in nuclear factor κB (NFκB) (p65) nuclear accumulation caused by exercise-induced muscle trauma. Massage was also found to decrease the production of the inflammatory cytokines, tumor necrosis factor-α (TNF-α) and interleukin-6 (IL-6), and to reduce heat shock protein 27 (HSP27) phosphorylation, ultimately decreasing the cellular stress resulting from muscle fiber injury. Massage is also believed to decrease emotional stress through activation of the autonomic nervous system, leading to a variety of neuroendocrine effects.

Clinically, massage has been shown to be of potential benefit for a number of conditions, including neck pain, low back pain, constipation, high blood pressure, lymphedema, stress, and depression. A randomized controlled trial of massage for osteoarthritis of the knee found that an 8-week course of massage decreased pain and improved function, with many of the effects persisting for weeks after cessation of treatment.■ Massage appeared to be a viable option as an adjunct to more conventional treatment modalities.

Massage is safe in most settings. Although massage is not entirely risk free, serious adverse events are probably true rarities. Massage should be avoided over rashes, open wounds, fractures, blood clots, or a tumor and is controversial in patients with lymphatic malignancies. Massage can result in increased soreness or bruising and should done with caution in anyone with a bleeding disorder such as thrombocytopenia.

Movement Therapy

Movement therapy is a term used to describe a broad category of approaches that address health and disease by focusing on restoring balance to the body using physical movement. It includes such therapies as yoga, tai chi, Alexander Technique, Feldenkrais Method, and others. Although some therapies involve complex movements and require a trained instructor, others can be self-directed using instructional materials such as videos or books. Yoga and tai chi in particular have gained in popularity in the West and have a growing body of research suggesting positive health benefits.

Originating in India, yoga has been practiced for more than 5000 years. There are hundreds of different types of yoga, which typically involve principles of proper exercise, relaxation, breathing, diet, and meditation and were traditionally practiced to develop one physically, emotionally, and spiritually. In the West, yoga practices have focused on exercise or physical postures (asana), breathing exercises (pranayama), and meditation or relaxation (dharana). Popular forms of yoga in the West include Ashtanga, a vigorous style often taught in the United States as power yoga; Bikram, practiced in rooms heated to about 100° F; Iyengar, a slow form of yoga with strict attention to posture and alignment; Kundalini, a more spiritual form using postures combined with hand positions, breathing, and meditation; and Hatha, which has a focus on postures and breathing exercises to promote a balance of physical health and mental calmness.

Numerous studies have explored the potential health benefits of yoga. A study in the United Kingdom involving 313 adults with chronic low back pain found that yoga led to more improvement in function than usual care when offered once a week for 3 months.■ In a meta-analysis, yoga reduced low back pain and back-specific disability but did not improve overall health-related quality of life compared with usual care, educational programs, and exercise programs.■

When guided by a well-trained instructor, yoga is generally safe for most healthy individuals. People with certain chronic conditions, such as glaucoma, hypertension, neck pain, or sciatica, should modify or avoid certain poses, as should women who are pregnant. Certain forms of yoga may be safer or more appropriate for people with particular conditions. For example, Bikram, or hot yoga, is best avoided in individuals with known heart disease, lung disease, or history of heat stroke. A review of comparison studies of yoga and exercise concluded that yoga may be as effective or superior to exercise in improving a number of health-related outcomes in both healthy and patient populations.[7]

Tai chi, also know as tai chi chuan, is an ancient Chinese practice involving a series of movements coordinated with breathing and practiced to strengthen the physical body, improve mental sharpness, and enhance the flow of energy or qi. The healthy flow of qi or this vital energy is thought to be a critical aspect of maintaining health in traditional Chinese medicine. A gentle form of movement that emphasizes continuous slow, often symmetrical flexion and extension of the upper and lower body, tai chi can often be practiced even by individuals with conditions such as heart disease or arthritis as well as by seniors at risk for falls.

Tai chi has been studied as an adjunct to conventional treatments for a number of conditions. A systematic review of the efficacy of tai chi for mostly healthy seniors found limited evidence that tai chi is effective in decreasing falls or blood pressure. A systemic review of tai chi for osteoarthritis came to a similar conclusion. There was some encouraging evidence to support efficacy, but future trials with larger patient samples and longer treatment periods were needed. However, a randomized trial in patients with fibromyalgia found that a 12-week course of tai chi compared with wellness education and stretching exercises led to significant improvement in pain as well as quality of life.■ Another randomized controlled trial in patients with mild to moderate Parkinson disease found that tai chi, compared with resistance training or stretching, reduced balance impairments, with additional benefits of improved functional capacity and reduced falls.■

As with other movement therapies, tai chi is best practiced under the guidance of a trained instructor, although it can be learned from videos or books. Safe for most populations, guidelines for appropriate practice of tai chi are the same as those for other land-based exercise programs.

Relaxation Techniques

Relaxation techniques involve a broad range of therapies and techniques, including meditation, yoga, and tai chi, which have been practiced for thousands of years for their purported mental, physical, and spiritual benefits. In more modern times, a number of techniques have been developed with the intent of eliciting the "relaxation response." The relaxation response leads to decreased sympathetic nervous system activation and has been shown to increase α waves on electroencephalogram. Through an effect on the limbic system and its influence on the hypothalamic-pituitary-adrenal axis, there is a subsequent slowing of heart rate and respiratory rate, as well as numerous other neuroendocrine effects, including decreased plasma cortisol. Common techniques include progressive relaxation, breathing exercises, guided visualization, biofeedback, and autogenic training.

Although commonly used to control or manage stress, relaxation techniques have been studied for a number of medical conditions, including anxiety, pain, irritable bowel syndrome, diabetes, premenstrual syndrome, tension headaches, and smoking cessation. Relaxation techniques and meditation programs can provide small to moderate reductions in stress from a wide range of conditions. Relaxation techniques can lead to improvement in both acute and chronic pain, but little evidence exists that the improvement is sustained over time.[8]

Relaxation techniques are a safe, typically low-cost option for patients in need of managing stress more effectively or as a part of an overall plan to manage any of a myriad of stress-related conditions. Given the broad diversity of options, it is important for patients to find a technique that feels most comfortable to them based on goals, personality, beliefs, and lifestyle.

Spinal Manipulation

Spinal manipulation is a method based on the belief that misalignment of the spine can have deleterious effects on health. The technique typically involves correction of a subluxation of the spine by applying a sudden force to the vertebrae or other joint while the patient is lying in various positions on an examining table. Chiropractic manipulation is similar to osteopathic manual therapy practiced by osteopathic physicians. However, osteopaths are medical physicians who may or may not use manipulation as a part of their treatment options. Whereas chiropractors may use a range of modalities, their main focus is on manipulation and restoring of proper alignment of the spine. According to the 2007 NHIS study, more than 18 million adults and more than 2 million children had undergone chiropractic or osteopathic manipulation during the previous 12 months.

The efficacy of manipulation has been studied for a number of diverse conditions, with most studies focused on musculoskeletal disorders. A review of the evidence concluded that manipulation was effective for acute, subacute, and chronic low back pain; migraine and cervicogenic headache; cervicogenic dizziness; several extremity joint conditions; and acute or subacute neck pain.[9] The existing evidence was found to be inconclusive for cervical neck pain of any duration, and for mid-back pain, sciatica, tension-type headache, cocydynia, temporomandibular joint disorders, fibromyalgia, premenstrual syndrome, and pneumonia in older adults.

Although minor side effects such as soreness or light-headedness are not uncommon, overall the risk for a serious adverse event is very low. Concern has been raised that manipulation of the cervical spine may put patients at increased risk for vertebrobasilar artery stroke. However, any small increased risk for such a stroke associated with both chiropractic care and visits to primary care physicians may be because such patients were already having headaches or neck pain because of impending or ongoing vertebral artery dissection.

Energy Therapies

Energy therapies include a number of approaches in which the practitioner intends to channel healing energy (typically through the hands) into the person seeking help in order to restore balance of energy in the body and health. The core concept is that all humans have a subtle vital energy or biofield that flows through them and can be manipulated or used to influence health. Examples of therapies that use this concept are therapeutic touch, healing touch, Reiki, qi gong, and intercessory prayer (prayer for an individual that is specifically directed at that person's health).

NCCAM distinguishes two categories of energy therapies or energy medicine: the veritable and the putative. Veritable energy therapies involve energy that can be measured, such as light therapy or electromagnetic radiation (radiation therapy), and are not considered CAM. Putative energy therapies are not measurable in a reliable way and involve theoretical manipulation or modulation of the vital force or biofield as described previously.

Putative energy therapies have been challenged as being nonplausible biologically and as such are perhaps among the more controversial therapies categorized as CAM. Despite that, prayer for health was the most commonly used intervention in the 2007 NHIS report, with approximately 30% of respondents having had others pray for their health. Approximately 1% had used Reiki and 0.5% qi gong.

A review of the literature on energy healing and pain, focused on Reiki, therapeutic touch, and healing touch, concluded that despite interest in these modalities, particularly in the nursing practice literature, few well-conducted studies existed. A 2008 study funded by NCCAM assessed the efficacy of qi gong in the treatment of osteoarthritis of the knee. This randomized controlled trial comparing two qi gong masters and a "sham" master found that although qi gong may have benefit for patients with osteoarthritis of the knee, the two healers were not equivalent.[10] This study points out the challenge of determining the qualification and competency of energy therapy providers for those interested in pursuing energy therapies as a possible therapeutic modality. Despite the lack of definitive research, energy therapies remain popular with patients, and putative energy therapies are generally regarded as offering no measurable risk.

WHOLE MEDICAL SYSTEMS

It is important to recognize that many of the therapies and approaches described previously come from complete systems of healing, or *whole medical systems*. These systems, with their own particular paradigm or way of viewing disease and health, include systems such as traditional Chinese medicine, Ayurvedic medicine, homeopathy, Native American healing, and naturopathy.

CONCLUSION

Although still controversial, use of CAM by both patients and conventionally trained providers has continued to increase. As evidenced by the growth of the Consortium of Academic Health Centers for Integrative Medicine, as well as such events as the Institute of Medicine's 2009 Summit on Integrative Medicine and the Health of the Public, integration and acceptance of the concepts and principles of integrative medicine into the mainstream and academic medical settings has also grown. This is perhaps a result of a realization that many of the principles of integrative medicine, such as a partnering of patients and providers, care that addresses the whole person, and an emphasis on not only treatment but also the broader concepts of health promotion and illness prevention, offer at least part of the solution to the challenges of our evolving health care system. All health care providers, present and future, should be familiar with these concepts, including the safe and appropriate use of a broad range of healing sciences and providers to facilitate the body's innate healing response, relieve suffering, and optimize vitality.

PRINCIPLES OF GENETICS

BRUCE R. KORF

The elucidation of the structure and function of the genome is one of the great scientific triumphs of the 20th century. The relevance of inheritance to health and disease probably has been recognized throughout history, but it is only during the last century that the rules governing inheritance and the mechanisms whereby genetic information is stored and used have come to light. The application of this knowledge to medical practice had long been focused on relatively rare monogenic and chromosomal disorders. Major contributions have been made in these areas in the form of approaches to genetic counseling, genetic testing, prenatal diagnosis, newborn screening, carrier screening, and, to a limited extent, treatment. As important as these contributions are, however, their impact has been limited by the rarity of these disorders. Powerful tools resulting from the sequencing of the human genome are changing this situation (Chapter 43).[1] Genetic factors that contribute to common and rare disorders are being identified, leading to new approaches to diagnosis, prevention, and treatment. Genetics and genomics are increasingly occupying center stage in medical practice, guiding treatment decisions and preventive strategies. This chapter reviews the paradigm whereby genetics is being integrated into the routine practice of medicine.

GENETIC CONTRIBUTION TO DISEASE

It may be argued that no disorder is either completely determined genetically or completely determined by non-genetic factors. Even monogenic conditions, such as phenylketonuria, are modified by the environment, in this case by dietary intake of phenylalanine. Genetically determined host factors are known to modify susceptibility to infection or other environmental agents. Even individuals who are victims of trauma may find themselves at risk in part because of genetic traits that affect behavior or ability to perceive or escape from danger.

Multifactorial Inheritance

Complex traits that are important for both health and disease are the result of an interaction of multiple genes with one another and with the environment (Fig. 40-1). In some cases, individual genes or environmental factors contribute overwhelmingly to the cause of a disorder, as with a genetic condition, such as neurofibromatosis or Marfan syndrome, or an acquired disorder, such as bacterial infection or trauma. Other times, there may be interplay among many factors, making it difficult to dissect out the specific genes or environmental exposures.

From a medical perspective, it is helpful to divide the genetic contribution to disease into three categories: (1) high-penetrance monogenic or chromosomal disorders; (2) monogenic versions of common disorders; and (3) complex, multifactorial disorders. Each of these has an impact on medical practice in distinctive ways.

High-Penetrance Monogenic or Chromosomal Disorders

High-penetrance monogenic or chromosomal disorders are the disorders that most clinicians think of as "genetic conditions" (Chapter 41). They include rare but familiar single-gene disorders, such as neurofibromatosis, Marfan syndrome, and cystic fibrosis, and chromosomal abnormalities, such as trisomy 21 (Down syndrome). Several thousand distinct human genetic disorders have been described and cataloged in *Mendelian Inheritance in Man* (available at www.omim.org). These include mendelian dominant or recessive disorders, sex-linked disorders, and conditions that are due to mutations within the 16.6-kilobase mitochondrial genome. They also include major chromosomal aneuploidy syndromes and syndromes associated with duplication or deletion of small regions of the genome that result in either reproducible syndromes, such as Williams syndrome (deletion of contiguous loci from a region of chromosome 7), or nonspecific intellectual disability or autism spectrum disorder.

ROLE OF THE NONSPECIALIST

Because of the rarity of many of these conditions, most practitioners have limited experience with a given disorder and are likely to need to refer the patient to an appropriate specialist for assistance with diagnosis and management. Nevertheless, the nonspecialist has many distinct roles in the care of these patients. These roles begin with recognition of the fact that the patient may have such a disorder and arrangement for appropriate diagnostic evaluation.[2] Many genetic disorders produce obvious signs or symptoms that at least prompt referral even if they are not immediately suggestive of a diagnosis. Others can be more subtle, with nevertheless significant consequences if the diagnosis is missed. An example is Marfan syndrome (Chapter 260). The physician needs to be alert to the physical characteristics of patients with Marfan syndrome because life-threatening aortic dissection can be avoided with appropriate monitoring and treatment. Table 40-1 lists examples of some adult-onset monogenic conditions with which the internist should be familiar.

Treatment of Patients with Genetic Disorders

The treatment of patients with genetic disorders may require the assistance of a specialist, but the nonspecialist is likely to be the first contact when an affected individual is ill. The primary care physician needs to be familiar with the disorder and major potential complications. For example, the patient with neurofibromatosis who experiences chronic back pain may be presenting with a malignant peripheral nerve sheath tumor, requiring more aggressive evaluation than would be typical for an unaffected individual with back pain. Formation of a good working relationship between the specialist and nonspecialist is crucial to ensure effective care.

The nonspecialist also has an important role in supporting the patient and helping to explain the difficult choices that may be offered for management. This includes providing support for patients who have disorders that cannot be treated and for the emotional impact that accompanies knowledge that a disorder may be transmitted to one's offspring or shared with other relatives. Most patients have little understanding of the mechanisms of genetics and genetic disease. Although the responsibility to explain these issues may reside with specialists and counselors, the primary care physician has an important supportive role.

ADVANCES IN GENETICS

Many of the disorders in this group have been known for a long time, but more recent advances in genetics have had a substantial impact on approaches to diagnosis and management. Genetic testing has been refined with the advent of molecular diagnostic tests that detect mutations within individual genes. Even rare disorders may be amenable to diagnostic testing; a database of testing laboratories can be found on the Internet (available at www.genetests.org or at www.ncbi.nlm.nih.gov/gtr/). Whole-genome scanning using cytogenomic microarrays is revealing small deletions or duplications in patients with disorders such as autism spectrum disorder, for whom standard chromosomal analysis had previously been unrevealing. Sequencing of the entire coding region of the genome ("*whole exome sequencing*") or the entire genome itself ("*whole genome sequencing*") is now being applied clinically.[3] (Actually, these tests do not detect every possible gene or DNA base, hence the use of the word "whole" is disputed, but the techniques do look across the entire genome, so the word "whole" distinguishes these from approaches that target specific genes.) Population screening for carrier status for autosomal recessive disorders has been offered for many years, with specific ethnic groups being offered testing for conditions of high prevalence in the group. Genomic approaches are now making it possible to vastly expand the scope of testing, increasing the numbers of conditions tested and making it possible to offer a similar comprehensive screen of dozens or even hundreds of genes regardless of ethnicity. Prenatal screening for trisomy can be offered noninvasively by sequencing of fetal DNA isolated from maternal blood. Newborn screening is being expanded beyond inborn errors of metabolism such as phenylketonuria and galactosemia, with the advent of tandem mass spectrometry and the availability of a standardized panel of tests.

Finally, treatment of some monogenic disorders is becoming feasible. Life expectancy for patients with cystic fibrosis has been increasing gradually with better treatments for chronic lung disease; dietary therapy is available for many inborn errors of metabolism; novel therapies that use either pharmaceuticals or gene or enzyme replacement strategies are in use or being tested for many conditions. The principles of management of genetic disorders are evolving rapidly, and care of patients increasingly requires active partnership of specialists and primary care physicians. Moreover, individuals with congenital disorders such as Down syndrome are routinely surviving to adulthood and require primary care physicians who are familiar with their special needs.

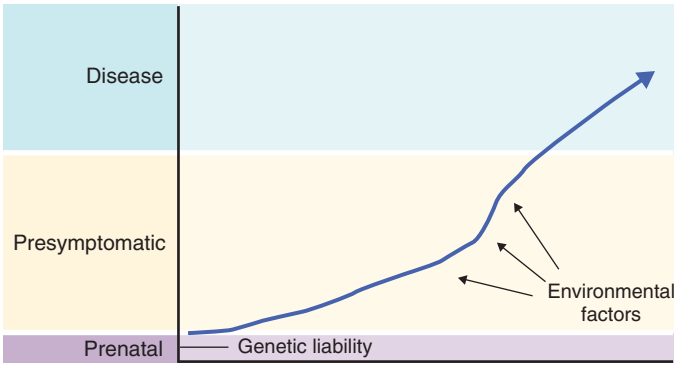

FIGURE 40-1. Multifactorial etiology of disease. An individual is born with a genetic liability but remains in a presymptomatic state for some time until additional events occur, including exposure to environmental factors, that result in crossing a threshold that is identified as *disease*. In instances of high-penetrance monogenic disorders, the genetic liability may be overwhelming. In other instances, genetic factors may contribute only slightly to disease risk.

TABLE 40-1 HIGH-PENETRANCE SINGLE-GENE DISORDERS THAT MAY PRESENT IN ADULTHOOD, WITH SOME MAJOR MEDICAL IMPLICATIONS*

DISORDER	INHERITANCE	MAJOR MEDICAL IMPLICATIONS
CARDIOVASCULAR		
Marfan syndrome	AD	Risk for aortic dissection; lens dislocation
Long QT syndrome	AD, AR	Arrhythmia, sudden death
RENAL		
Adult polycystic kidney disease	AD	Renal failure
PULMONARY		
α_1-Antitrypsin deficiency	AR	Emphysema, cirrhosis
NEUROLOGIC		
NF1	AD	Benign and malignant nerve sheath tumors, gliomas
NF2	AD	Schwannomas (especially vestibular), meningiomas
Von Hippel-Lindau	AD	Hemangioblastoma of cerebellum, brain stem, eye; pheochromocytoma; renal cell carcinoma
Huntington disease	AD	Movement disorder, psychiatric disorder, dementia
HEMATOLOGIC		
Globin disorders	AR	Stroke, iron overload
ENDOCRINE		
MEN syndromes	AD	Tumors of thyroid and parathyroid, pheochromocytoma

*See Table 40-2 for examples of lower penetrance disorders.
AD = autosomal dominant; AR = autosomal recessive; MEN = multiple endocrine neoplasia; NF = neurofibromatosis.

Monogenic Versions of Common Disorders

Not all monogenic disorders produce obscure phenotypes, and not all common disorders have complex multifactorial causes. Some common disorders occur in some families as single-gene traits (Table 40-2). This is usually true for only a proportion of affected individuals, but in some cases, it is a significant proportion and represents an important group of patients to be recognized.

Breast Cancer

An example is breast cancer (Chapter 198). Familial predisposition to breast and ovarian cancer in many cases is attributable to mutation of *BRCA1* or *BRCA2*. Women who inherit a mutation in one of these genes face a high risk for eventually developing breast or ovarian cancer—more than 80% by age 70 years for breast cancer. Women at risk because of mutation do not look different from women with sporadic breast cancer but can be distinguished by many features, including family history of breast or ovarian cancer in multiple relatives, early age at onset of cancer, and multifocality of the cancer (e.g., bilateral breast cancer or breast and ovarian cancer).

TABLE 40-2 SINGLE-GENE DISORDERS WITH INCOMPLETE PENETRANCE THAT MAY ACCOUNT FOR INHERITED FORMS OF SELECTED COMMON DISORDERS

DISORDER	INHERITANCE: GENES	MAJOR MEDICAL IMPLICATIONS
Hemochromatosis	AR: *HFE*	Cirrhosis, cardiomyopathy, diabetes mellitus
Thrombophilia	AD, AR: multiple genes	Deep vein thrombosis
Breast and ovarian cancers	AD: *BRCA1, BRCA2*	Breast and ovarian cancers
Familial adenomatous polyposis	AD: *APC*	Multiple colonic polyps, colon cancer
Lynch syndrome	AD: DNA mismatch repair genes	Colorectal cancer, endometrial cancer
Maturity-onset diabetes of the young	AD: multiple genes	Diabetes mellitus
Cardiomyopathy	AD: genes involved in cardiac contractile apparatus	Arrhythmia, heart failure

AD = autosomal dominant; AR = autosomal recessive.

Colon Cancer and Other Common Disorders

Another example from cancer genetics is colon cancer (Chapter 193). Two syndromes, familial adenomatous polyposis and Lynch syndrome, are autosomal dominantly inherited and convey a high risk for colon cancer. Other noncancer examples are hemochromatosis (Chapter 212), in which cirrhosis, cardiomyopathy, diabetes, joint disease, and other problems ensue from excessive iron absorption; 10% of whites carry an allele that predisposes to this recessive disorder. Mutations in the factor V gene or the prothrombin gene occur commonly and predispose to deep vein thrombosis (Chapter 176). Rarer examples include inherited forms of cardiomyopathy, hypertension, and familial hypercholesterolemia.

Management

The physician may be called on to address these disorders in many ways. There is a compelling reason to make an early diagnosis of hemochromatosis because the complications can be prevented, but not reversed, by phlebotomy and subsequent monitoring of iron stores. Individuals at risk for colon cancer can be offered surveillance with colonoscopy or surgical resection of the colon to reduce the risk for cancer. Individuals at risk for breast and ovarian cancer likewise can be offered surveillance, chemoprevention, or surgery. The benefits of knowledge of genetic risks are less clear in some instances. Carriers of the factor V Leiden mutation would not be treated with anticoagulation until after an event of thrombosis, and the treatment may not be different for a carrier versus a noncarrier. In some cases, however, knowledge of carrier status may help ensure prompt diagnosis or avoid situations of high risk.

Genetic Testing

As with other medical tests, the physician should carefully consider risks, benefits, and clinical utility in deciding to use a genetic test. Some distinct ethical and legal risks may apply to some genetic tests. These may include anxiety, stigmatization, guilt, and possibly discrimination for insurance or employment. Some of these risks may be addressed by legislation to maintain privacy of genetic information, such as the Genetic Information Nondiscrimination Act of 2008, but the risks for anxiety, guilt, and stigmatization cannot be legislated away. To some extent, further research may improve the basis for surveillance or lead to effective treatments. For now, many of these disorders present a double-edged sword of potentially useful knowledge and potentially harmful information.

ROLE OF THE PHYSICIAN

The role of the physician in dealing with monogenic disorders includes recognition of individuals at risk and participation in formulation of a care plan.[4] Individuals at risk may not be identifiable by physical appearance and usually are not evident from medical history or physical examination findings. The most valuable screening tool is the family history. Directed questioning about a family history of major monogenic disorders, especially breast, ovarian, and colon cancer, as well as hypercholesterolemia, hypertension, deep vein thrombosis, cirrhosis, and diabetes, can identify the occasional patient with mendelian segregation of these common disorders. Even if the information is of uncertain reliability, eliciting a family history can prompt referral for further evaluation, documentation of the family history, and consideration for genetic testing. The physician's job is not simply to identify individuals at risk; some people believe they are at high risk even in the absence of well-documented risk factors. Addressing these misconceptions can bring peace of mind and usually does not require genetic testing.

Complex, Multifactorial Disorders

Understanding the genetics of common disorders is one of the great challenges of modern medicine, with the promise of major returns in terms of prevention, diagnosis, and treatment. The etiology of these disorders is complex in that they result from an interaction of multiple genes with one another and with environmental factors. The specific genes that are relevant may be different from one person to the next. Identification of these genes is difficult given this heterogeneity and the relatively small impact that any particular gene may have in a particular person.

POPULATION STUDIES

Dissection of the genetic contribution to common disease cannot be accomplished by the standard genetic approaches involving study of rare variants or family-based linkage studies. Most recent efforts have focused on study of large groups of patients, comparing the prevalence of particular genetic markers in case patients and control subjects. The availability of markers has been boosted by the identification of *single-nucleotide polymorphisms* (SNPs) (Chapter 43). These are differences in single DNA bases between individuals that occur every several hundred bases. Some of these account for common genetic differences between people, including differences that may contribute to disease. The catalog of SNPs currently includes several million variants; it has been found that the genome has evolved as blocks of clusters of genes, making it possible to use only a limited number of SNPs within a given region to determine whether there is a gene in that region that is associated with a disease. Since completion of the HapMap Project, there has been a dramatic increase in the number of SNPs found to be associated with common disorders. For most disorders, however, the total contribution to heritability of the condition has not been accounted for by SNP association studies.

GENETIC RISK ASSESSMENT

The goal of genetic risk assessment is the identification of individuals at risk for disease before the onset of signs or symptoms. In principle, the genetic factors could be identified at birth, or any time in life, by testing a DNA sample. Any individuals found to be at risk might be offered treatment in advance of onset of the disease to avoid complications or might be advised to modify their lifestyle to avoid exposure to environmental factors that might increase risk for disease. Genetic testing has been offered on a direct-to-consumer basis by some companies, although the clinical validity and clinical utility of such testing is a matter of debate.

Although the concept of genomic risk assessment would appear to be an attractive paradigm, many questions may be raised about its practicality and implementation. First, predictive testing is useful only insofar as it guides further management. This is likely to be a moving target because ability to test for risk can be developed more quickly than ability to modify that risk. The utility of interventions may be valued differently by different people. This already has been the case for testing of disorders such as breast cancer. Some women at risk choose not to know their *BRCA* status because the options, including surveillance or prophylactic surgery, are unacceptable to them. If there were a low-cost, safe, and effective treatment that would neutralize any risk the decision to test would be simple, but short of that, there are reasonable arguments on both sides of the issue of whether to test. For many disorders, it will take a long time to show the efficacy of any intervention because there may be a period of many years between the test and the onset of a disorder. Unless surrogate markers can be identified and followed, the task of proving a benefit to predictive testing may require years to decades in some instances.

Predictive Value of Genetic Testing

A second issue surrounds the degree to which genetic testing would be predictive. In patients with suspected genetic conditions, whole exome sequencing currently can make a diagnosis in about 25% of cases.[5,6] Most genetic tests, however, are likely to involve detection of relatively common polymorphic alleles that account for small increments of odds of getting a disease. The predictive value of these tests would be modest, perhaps too low to induce an individual to modify behavior or to take medication. Here, again, much depends on the efficacy of any intervention that can be offered. There may be some disorders for which testing would have substantial predictive value and clinical utility and others for which testing would not be justified.

Social and Ethical Issues

A third concern relates to social and ethical issues. Will people use test results as an excuse to pursue self-destructive behaviors, having received what may be false reassurance of "immunity"? Will people misinterpret results of testing in terms of a simplistic notion of genetic determinism, erroneously believing that their futures have been written, leaving them no recourse but to meet their fate? The rapid pace of technologic change is going to challenge the ability of the social and legal systems to keep pace.

Service Models

Finally, there are questions of the ideal context in which to offer such testing. The personal genomics companies provide their services directly to the consumer in most cases. This creates the obvious risk for incorrect interpretation of results by the patient, although it is not clear that the health care work force is otherwise prepared to deal with the challenges of interpretation of genome-wide studies. The challenges are increasing as the cost of genome sequencing continues to plummet. Genome sequencing also raises the complex question of how to handle incidental findings (i.e., discovery of an unexpected disease risk that may or may not be amenable to medical intervention).

DISEASE STRATIFICATION

A second application of genomics in medical practice entails stratification of disease. Even if genetic testing is not used to predict individuals at risk, it may well be used to determine the most appropriate treatment for a clinically diagnosed disorder. Most common disorders, such as hypertension and diabetes, are symptom complexes that probably result from a variety of causes. The particular combination of causes may differ in different individuals and may respond to different types of treatments. Choice of antihypertensive drug may come to depend on genetic testing to determine the specific cause of hypertension in a patient. The concept of disease stratification is particularly well developed in treatment of cancer, where targeted multigene tests and even genome sequencing is increasingly being used to guide therapy. It is likely that genetic tests eventually will accompany many if not most treatment decisions.

EFFECTS AND IDENTIFICATION OF DRUGS

Aside from helping to choose the most efficacious drug, genetic testing may play a role in avoidance of side effects and in appropriate dosing. Many drugs are known to be associated with rare side effects, some of which are sufficiently severe as to lead the drug to be withdrawn from use. Some of these side effects may occur only in individuals who are susceptible on the basis of having a particular allele at a polymorphic locus. An example is the association of polymorphisms in certain sodium or potassium channel genes with risk for arrhythmia on exposure to specific drugs.

Absorption and metabolism of drugs are largely under genetic control. Several polymorphisms are known to lead to particularly rapid or slow metabolism, accounting for individuals who experience dose-related side effects or lack of efficacy at standard dosages (Table 40-3). Detection of these polymorphisms would allow customization of drug dosage to an individual's pattern of metabolism, increasing the likelihood of efficacy without a prolonged period of trial-and-error dosing.[7]

The greatest gift of genetics and genomics to medicine may be in the ability to identify new drug targets and develop new approaches to treatment. Identification of genes that contribute to common disorders is revealing the cellular mechanisms that lead to disease. This knowledge offers the opportunity to develop new pharmaceutical agents that would target the physiologic mechanisms more precisely, leading to drugs that work better and cause fewer

TABLE 40-3 GENES IN WHICH COMMON POLYMORPHISMS AFFECT RATES OF DRUG METABOLISM OR ACTION

GENE	MEDICATIONS (EXAMPLES)
CYP2C9	Phenytoin, warfarin
CYP2D6	Debrisoquin, β-blockers, antidepressants
VKORC1	Warfarin
UGT1A1	Irinotecan
Thiopurine methyltransferase	Mercaptopurine, azathioprine
N-acetyltransferase	Isoniazid, hydralazine
CYP2C19	Clopidogrel

side effects. New approaches to gene replacement or insertion of genes into cells as localized drug delivery systems also may be developed. The treatment of common disorders likely would entail the use of approaches developed as a result of genomics even in cases in which genetic testing is not used to predict individuals who are at risk.

CONCLUSION

Most physicians in practice today trained before the elucidation of the sequence of the human genome. Nevertheless, physicians will be using the products of the genome project increasingly in their day-to-day practice during the coming years. Whether they are providing care for a patient with a rare genetic disorder or for a patient with a common condition not usually regarded as genetic, management choices increasingly will be informed by tests and treatments that in some way are based on information from the genome sequence.

The essence of the encounter between a physician and a patient can be distilled to two questions: Why this person? Why this time? A person who seeks medical care is doing so as the product of human evolution, having an ancestry associated with certain genetic vulnerabilities, because of inheritance of certain familial risk factors, because of exposure to some environmental factors, because of a particular physiologic process gone awry, because of behavioral traits that lead the person to seek medical care, because of prompting by family or friends to go to the doctor, because society makes medical services available, and because the person can afford to seek care. Genetics cannot answer all of these questions, but it is providing the key to addressing many of the biologic questions that underlie the medical mysteries that have puzzled humankind for generations.

REVIEW QUESTIONS

1. A couple have a child with autism spectrum disorder in whom chromosomal analysis has been done and was normal. Which of the following is recommended to search for a possible genetic cause?

A. Cytogenomic microarray testing
B. Fluorescence in situ hybridization
C. High-resolution chromosome banding
D. Whole exome sequencing
E. Whole genome sequencing

Answer: A Cytogenomic microarray testing now can detect small copy-number changes (deletions or duplications) that would not be detected by standard cytogenetic analysis, including high-resolution banding.

2. A man has a direct-to-consumer genomic test and is found to have a 1.2 increased odds of type 2 diabetes. The basis for this testing is which of the following?

A. Sequencing a gene known to be involved in type 2 diabetes
B. Single-nucleotide polymorphism genotyping
C. Analysis of RNA sequences in a saliva sample
D. Whole exome sequencing
E. Whole genome sequencing

Answer: B Direct-to-consumer genomic testing is currently based on genotyping of a large number of single nucleotide polymorphisms. (See Population Studies.)

3. A woman requests genetic testing for risk for breast cancer. Which of the following would constitute a risk factor for familial breast and ovarian cancer?

A. History of tobacco use
B. Sister with breast cancer diagnosed at 40 years of age
C. Mother with ovarian cancer diagnosed at 80 years of age
D. Father with history of lung cancer
E. Maternal uncle with colon cancer

Answer: B A first-degree relative with early-onset breast cancer would constitute a risk factor for hereditary breast and ovarian cancer. (See Breast Cancer under Role of the Physician.)

4. A 40-year-old patient with Marfan syndrome seeks advice regarding medical surveillance. Which of the following represents the greatest health risk that may be subject to medical intervention?

A. Dislocation of joints
B. Dislocation of lens
C. Aortic root dilation
D. Cardiomyopathy
E. Skin laceration

Answer: C Aortic root dilation and risk for aortic dissection are the most important life-threatening risks for individuals with Marfan syndrome and are subject to monitoring and intervention. (See Role of the Nonspecialist.)

GENE, GENOMIC, AND CHROMOSOMAL DISORDERS

SANDESH C. S. NAGAMANI, PAWEŁ STANKIEWICZ, AND JAMES R. LUPSKI

THE HUMAN GENOME

Unprecedented technologic advances in molecular biology during the past two decades have enabled the determination of the entire DNA (deoxyribonucleic acid) sequence content of the human genome (Human Genome Project, HGP; http://web.ornl.gov/sci/techresources/Human_Genome/index.shtml) and establishment of a reference haploid genome.[1,2] Sequencing of other personal diploid human genomes and international collaborative efforts (http://www.1000genomes.org/) have generated DNA sequence data that have revolutionized our views on human history, evolution, and the genetic and genomic bases of disease.[3]

Human genomic DNA is packaged within the nucleus in 23 chromosome pairs, 22 autosomes, and 2 sex chromosomes, XX in females and XY in males. The diploid genome (2n) in each cell consists of two identical haploid copies of about 3×10^9 base pairs (bp), thus equaling in total 6 billion nucleotides. Most of the human genome consists of repetitive elements: tandem repeats (e.g., satellite sequences in centromeres), telomeric repeats, microsatellites, minisatellites, and short and long interspersed retrotransposable elements (e.g., *Alu* elements and LINE elements, respectively) (Table 41-1). These elements form constitutive heterochromatin, and their functional roles are not yet well elucidated. The unique "coding" DNA sequences comprise the minority of our genome and include about 23,000 protein-coding genes, conserved sequences that encode noncoding RNAs (i.e., not translated to protein), including microRNAs (miRNAs), small nucleolar RNAs (snoRNAs), and long noncoding RNAs (lncRNAs), as well as conserved regulatory elements. Although protein-coding sequences occupy only about 1 to 2% of the human genome, it has been demonstrated recently that most of our DNA may be transcribed into RNA.

Approximately 4 to 5% of the human genome, including both repetitive and unique sequences, is present in two or more copies in the haploid genome. DNA fragments larger than 1 kb and of DNA sequence identity greater than 90% have been termed *low-copy repeats* (LCRs) or *segmental duplications* (SDs). Most LCRs have arisen during primate speciation. A subset of LCRs with DNA sequence identity greater than 95% and longer than 10 kb can lead to local genome instability during both meiotic (constitutional) and mitotic (somatic) cell divisions, resulting in genomic rearrangements and conveying genomic disorders.

GENE

The concept of a gene can be traced back to 1865 when Gregor Mendel observed the inheritance of phenotypic traits in the garden pea, *Pisum sativum*. Mendel noted that two *factors* that we now know to be corresponding DNA loci (alleles) located on homologous chromosomes separate from each other during meiosis and segregate to two different gametes. This phenomenon of independent segregation is now known as *Mendel's first law*. *Mendel's second law* described the independent segregation of two different (nonallelic) loci during gamete formation. The *inheritance factors* or *units of heredity* encoding the genetic information were later defined as *genes*. We now define a *gene* as a fragment of DNA that carries the information used to transcribe it into a functional RNA (ribonucleic acid).

The DNA double helix is built of four nucleotides: two purine bases, adenine (A) and guanine (G), and two pyrimidine bases, thymine (T) and cytosine (C), all connected to deoxyribose sugars and linked by phosphodiester bonds at the 5′ and 3′ carbon of the sugar. (In RNA, thymine is replaced by uracil, U.) Three consecutive nucleotides (triplet codon) of the coding DNA encode an amino acid. There are 64 possible different codons (4^3 combinations) but only 20 amino acids; therefore, the genetic code has been termed *degenerate*. Most of the protein-coding genes in our genome comprise several coding regions or *exons* that are separated by noncoding *introns*. The entire gene (exons and introns) is transcribed into messenger RNA (mRNA) by RNA polymerase II starting from its 5′ end and continuing beyond the poly A recognition signal at the 3′ end. Typically, mRNA begins with a cap and terminates with a polyadenylated (polyA) tail at the 3′ end. In the subsequent process of splicing, the intervening noncoding introns are deleted, and the spliced, mature mRNA is translated into a polypeptide. The polypeptides start at the 5′ end (NH_2 terminus) with a methionine encoded by the AUG triplet. At the 3′ end (COOH terminus), the polypeptides are terminated by one of three terminating codons, UAA, UAG, or UGA (Fig. 41-1).

Micro-RNA (miRNA) (about 22 bp single-stranded RNA), *small nucleolar RNA* (snoRNA) (60 to 300 bp single-stranded RNA), and *long noncoding RNA* (lncRNA) (>200 bp RNA) are transcribed but are not translated. These noncoding RNAs are involved in many important biologic processes. There is evidence that dysregulation of noncoding RNA may have a role in cancer, cardiovascular, neurologic, and developmental disorders.

GENETIC AND GENOMIC VARIATION IN HUMANS

In addition to the Human Genome Project, the International HapMap (http://hapmap.ncbi.nlm.nih.gov), Human Genome Diversity (http://www.stanford.edu/group/morrinst/hgdp.html), ENCODE (http://www

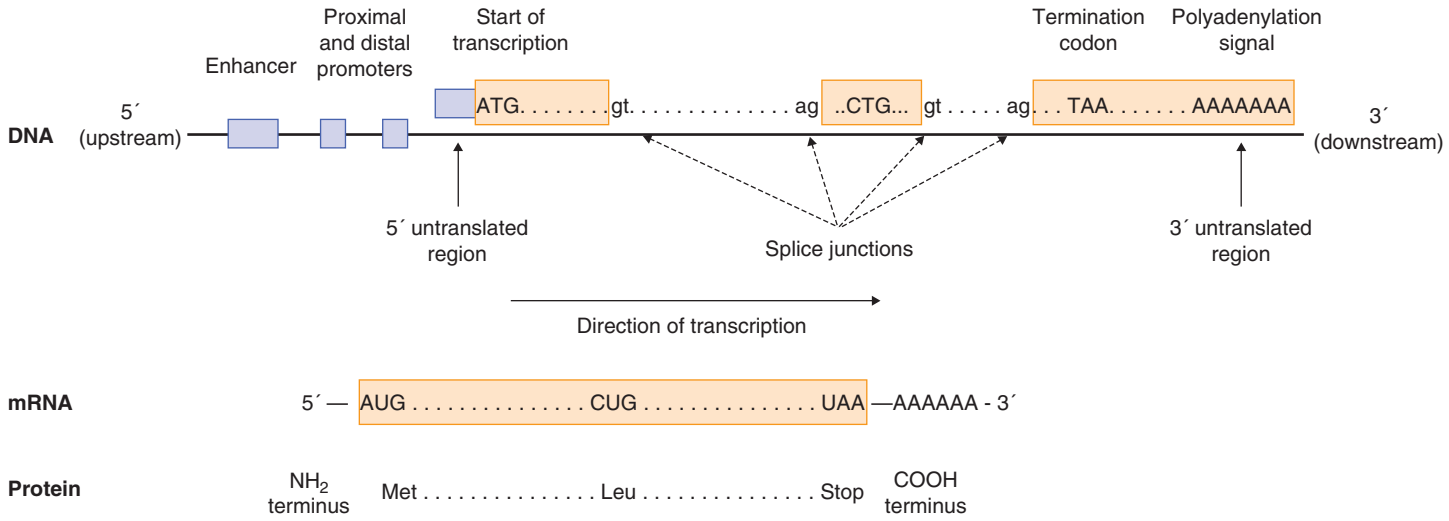

FIGURE 41-1. Gene structure. Schematic representation of the general structure of a typical human gene. Three exons are depicted as open rectangles. Note that the translation usually starts with an ATG triplet encoding methionine. The 5′ (upstream) portion of a gene corresponds to the NH_2 terminus, and the 3′ (downstream) segment encodes the COOH terminus of the polypeptide. Enhancers and promoters are shown as blue rectangles.

.genome.gov/10005107), 1000 Genomes project (http://www.1000genomes.org/), and other collaborative efforts, including personal genome sequencing projects, have revealed the tremendous and underappreciated extent of variation in the human genome.[3] Genetic variation consists of two major types: (1) nucleotide sequence changes, or single nucleotide variants (SNVs); and (2) genome structural changes, or copy-number variants (CNVs) (Fig. 41-2).

Single Nucleotide Variants

A genetic *polymorphism* is defined as a heterozygous DNA variation present in greater than 1% of the population (http://www.ncbi.nlm.nih.gov/SNP/, http://www.1000genomes.org/, http://evs.gs.washington.edu/EVS/). Genome-wide nucleotide variation uncovered in the early phase of DNA sequencing analyses showed that human genomes differ from the haploid reference genome mainly by single nucleotide changes. These differences have been termed *single nucleotide polymorphisms* (SNPs) and defined as a nucleotide change at a given position generated by substitution. Any two human beings differ on average by about 3.5 million SNPs (0.1% of the 3.0×10^9 reference haploid genome). Whereas most of these SNPs map outside of the exons, on average about 20,000 SNPs occur in coding regions, and among these, about 7000 to 10,000 are nonsynonymous (i.e., change the encoded amino acid).[3] It is important to note that SNPs located outside of the protein-coding regions can still exert phenotypic effects, such as by modifying gene regulatory elements, transcription factor–binding sites, generating splicing mutations, or affecting noncoding RNAs.

A set of consecutive SNPs (or other markers) is defined as a *haplotype*. A nonrandom association of markers in a population not interrupted by meiotic recombination (*crossing over*) is described as *linkage disequilibrium*. (Note that linkage disequilibrium exemplifies the exception to Mendel's second law).

Copy-Number Variants

A more recently characterized group of major polymorphic genetic variation in the human genome is represented by *structural changes*. High-resolution genome-wide analysis of human genome sequences has revealed higher-order architectural features, with a potential to cause genomic instability and extensive submicroscopic structural variations.[4] These structural variations consist of unbalanced CNVs, including deletions, duplications, triplications, insertions, and translocations, that differ from the normal diploid state, as well as balanced rearrangements such as genomic inversions. Recent analyses have revealed that about 11,700 CNVs (size > 443 bp) cover more than 112 million base pairs (Mb) (3.7%) of the reference human genome. A validated subset of these CNVs overlap 13% of the Reference Sequence (RefSeq) (http://www.ncbi.nlm.nih.gov/projects/RefSeq/RSG) genes and 12% of the Online Mendelian Inheritance in Man (OMIM) (http://www.ncbi.nlm.nih.gov/sites/entrez?db=omim) genes and was predicted to alter the structure of 12.5% gene transcripts and 5.5% mRNAs. On average, each individual harbors about 1000 CNVs that range in size between 500 bp and 1.2 Mb; the frequency of smaller CNVs (<1 kb) and indels (insertion or deletion of bases < 100 bp) is much higher than the larger rearrangements. It is noteworthy that any two human genomes contain more base-pair differences due to CNVs than to SNVs.

Despite all these recent achievements, the total number, position, size, gene content, and population distribution of CNVs remain obscure because we still do not have accurate and reliable molecular methods to study smaller

CNVs on a genome-wide scale in different populations, particularly when copy-number changes are greater than $n = 4$ or 5.

CNVs have been shown to be responsible for Mendelian diseases, non-Mendelian traits such as complex diseases, and common traits (including neurobehavioral traits), or to represent benign polymorphic variants (Chapter 40).[5] CNVs can lead to abnormal phenotypes by disrupting the gene structure or changing the copy-number of dosage-sensitive genes. However, long-range effects of CNVs involving nongenic sequences, leaving a gene intact, have been also demonstrated. Furthermore, evidence suggests that a combination of two or more CNVs at the same or different loci may be responsible for phenotypic variation. The genome-wide scale of phenotypic effects exerted by CNVs (genomic load) is unknown and awaits further studies.

A summary of CNVs can be found in the Toronto Database of Genomic Variants (http://projects.tcag.ca/variation). Many clinically relevant CNVs can be found in the Database of Chromosomal Imbalance and Phenotype in Humans using Ensembl Resources (DECIPHER) (https://decipher.sanger.ac.uk/information).

Tandem Repeats

Variable number of tandem repeats (VNTR), or *minisatellites*, and short tandem repeats (STRs), such as unstable dinucleotides, trinucleotides, and tetranucleotides—$(GT)_n$, $(CAA)_n$, or $(GATA)_n$—referred to as *microsatellites,* are highly variable. Both minisatellites and microsatellites have been successfully used in linkage and association studies that enable the mapping of traits and the identification of genes and loci responsible for both Mendelian disorders and complex traits. These highly polymorphic sequence repeats are extremely variable in the copy number of their repeating subunits; this property enables the use of a number of such markers to derive a unique pattern of marker genotypes for each human individual. Thus, such markers have been useful in DNA fingerprinting for identity testing and DNA forensics.

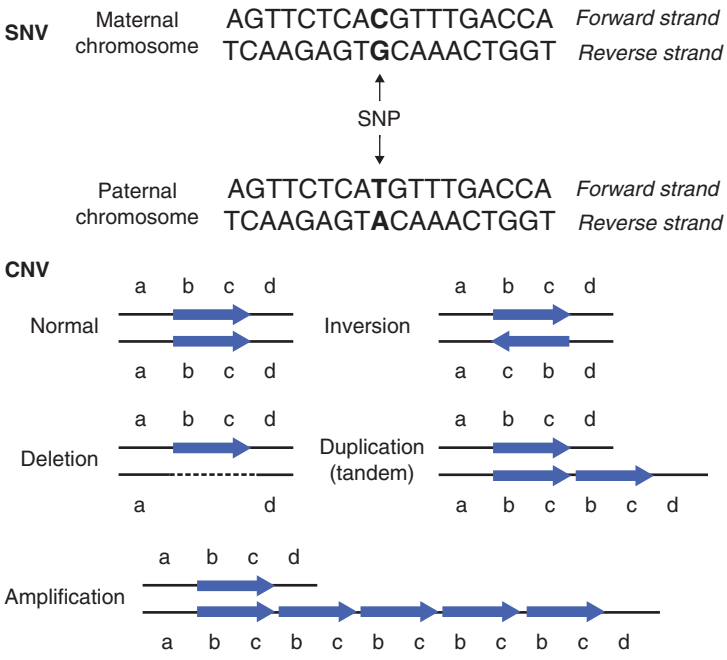

FIGURE 41-2. Genetic variation. (*Upper*) Heterozygous single nucleotide polymorphism (SNP, or single nucleotide variant, SNV) representing the most common transition C→T is shown. (*Bottom*) Structural genomic changes: a balanced inversion and the unbalanced copy-number variants (CNVs), deletion, duplication, and amplification are shown with *blue arrows* on two homologous chromosomes (*black lines*). The *dashed line* represents a deleted fragment of one chromosome.

Repetitive Elements

The other group of polymorphic elements in the human genome is represented by retrotransposons, long and short interspersed nuclear elements (LINEs and SINEs) (see Table 41-1). The most common *Alu* and L1 elements introduce recombinogenic genomic instability and insertional mutagenic activity; their positions within an individual human personal diploid genome can vary tremendously.[6] It has been recently estimated that repetitive elements may represent more than two thirds of the human genome.[7]

CHROMOSOMES

The recombined haploid (1n) human genome formed during meiosis is stored as chromosomes in female and male gametes. They merge at conception, and this diploid genome instructs the development of a zygote; the diploid human genome is subsequently transmitted to the mitotically dividing daughter cells. Human chromosomes can be distinguished from each other in a light microscope by differences in size and characteristic banding patterns after specific chemical staining (e.g., G-banding with Giemsa) when the chromosomes are arrested in a condensed phase (metaphase) of mitotic divisions.

Each human metaphase chromosome is composed of two chromatids that form short (p) and long (q) arms connected by a centromere built with α-satellite DNA. Based on the relative position of the centromere along the chromosome, chromosomes have been described as metacentric (similar-sized p and q arms), submetacentric (q arm significantly longer than p), and acrocentric (chromosomes 13, 14, 15, 21, and 22, with centromeres located close to the end of a chromosome) (Fig. 41-3).

Telomeres consist of repetitive DNA sequences (thousands of copies of TTAGGG repeats) located at the ends of both chromosome arms that are stabilized by a reverse transcriptase enzyme, *telomerase*, which adds TTAGGG sequence to the 3′ end of DNA strands. In contrast to germline and cancer cells, human somatic cells lacking telomerase gradually lose the telomeric sequences. As a result, cells reach the limit of their replicative capacity and fall into senescence.[8]

Chromosomal Aberrations

Microscopically visible chromosomal aberrations have been divided into numerical and structural aberrations and are found in about 1 in 160 live births.

Numerical Aberrations

The numerical aberrations typically result in lethality. Numerical aberrations are classified as either polyploidy (number of chromosomes are in multiples of haploid set of 23 chromosomes) or aneuploidy (with extra or missing chromosomes). Polyploidies such as triploidies (3n), 69,XXX, 69,XXY, and

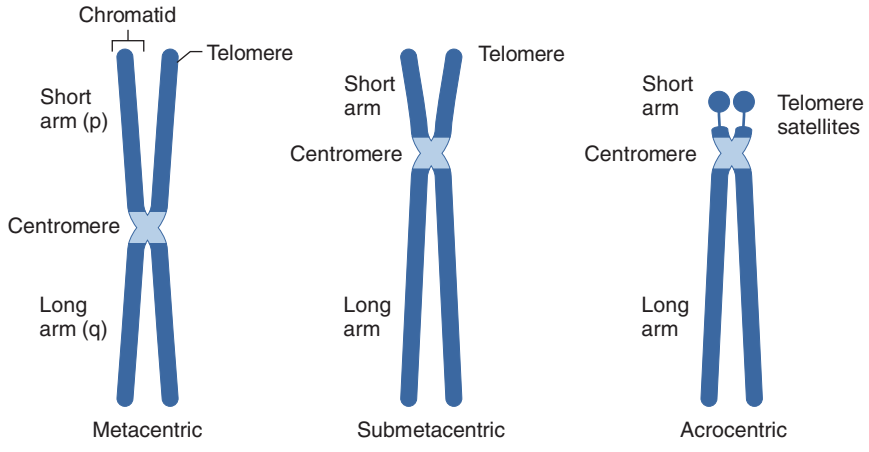

FIGURE 41-3. Types of metaphase chromosomes. Metacentric, submetacentric, and acrocentric chromosomes are composed of two arms connected by a centromere. Each chromosome arm consists of two chromatids.

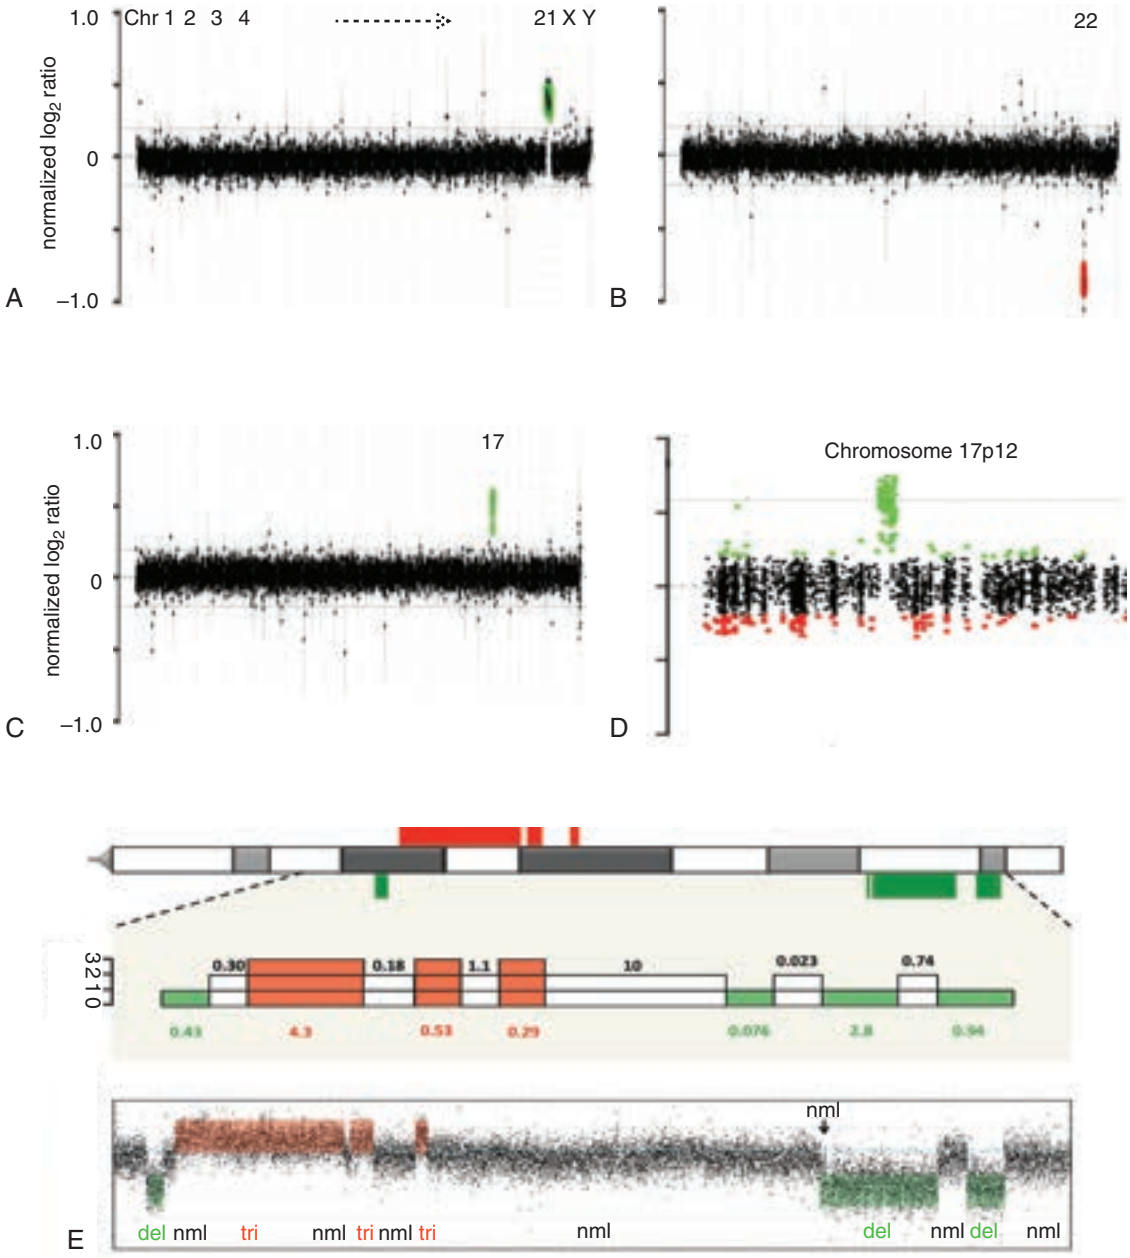

FIGURE 41-4. Assaying copy-number variants (CNVs). Plots of array-based comparative genomic hybridization from patients with genomic rearrangements. Each "dot" on the plot represents an oligonucleotide that interrogates specific regions of the human genome from chromosome 1 (depicted on left) to the sex chromosomes depicted on the right). Gain of copy number is depicted in green, and loss of copy number is depicted in red. A, Patient with Down syndrome showing gain (three copies) of chromosome 21. B, Patient with congenital heart disease and velocardiofacial syndrome with a 3 Mb deletion of chromosome 22q11.2. C, Patient with autosomal dominant sensorimotor neuropathy (CMT1A) with a gain of copy number (duplication) on chromosome 17p12. D, Expanded view of the 17p12 duplication shown in C. E, Complex genomic rearrangement in a pediatric patient with epilepsy and hypotonia showing multiple breakpoints in a single chromosome. The rectangular boxes below the ideogram of the chromosome show copy-number of genomic segments, and the numbers depict the size of the CNVs in Mb. del = Deletion; nml = normal; tri = triplication.

69,XYY, and tetraploidies (4n), 92,XXYY or 92,XXXX, are caused by abnormal fertilization of the egg by two sperms, or by a failure in zygote division, respectively. The most commonly detected viable chromosomal aneuploidies, trisomies and monosomies, involve chromosomes X, Y, 21, 18, and 13 and arise as a result of meiotic nondisjunctions.

Sex chromosome aneuploidies are more common and are found in 1 in 440 newborns. Monosomy X (45,X cell line) in female patients with Turner syndrome is identified in one in every 4000 female newborns. However, this birth rate represents only 1% of all fetuses with 45,X because more than 99% result in miscarriage. (This is similar to the most frequent fetal aneuploidy, trisomy 16, that results in 100% miscarriages.) In most cases, the 45,X cell line is found as a mosaic along with another cell line that has either a normal karyotype or a structural rearrangement of the X chromosome (e.g., deletion of the short arm, ring chromosome, or isochromosome of the long or short arms). One in every 1000 males has a 47,XXY or 47,XYY chromosome complement; the former results in Klinefelter syndrome, whereas the latter typically has mild if any manifestations.

In contrast to gonosomes, monosomies of all autosomes are lethal. The only autosomal trisomies compatible with life are found in patients with Down syndrome (trisomy 21, 1 in every 670 newborns) (Fig. 41-4A), Edwards syndrome (trisomy 18, 1 in 7500 newborns), and Patau syndrome (trisomy 13, 1 in every 22,700 newborns).

Incomplete supernumerary chromosomes are termed *marker chromosomes*. They usually originate from acrocentric autosomes (~50% from chromosome 15) and are found in 1 in 4000 newborns. The severity of the abnormal phenotypes in carriers of marker chromosomes varies among different chromosomes.

Structural Aberrations

Chromosomal deletions and duplications have been categorized as microscopically visible or submicroscopic, terminal or interstitial, recurrent or nonrecurrent. The most frequent are recurrent common-sized rearrangements flanked by directly oriented LCRs or SDs that mediate nonallelic homologous recombination (NAHR). For example, a 3 Mb microdeletion

in chromosome 22q11.2 that results in DiGeorge (velocardiofacial) syndrome is found in 1 in 4000 newborns (Fig. 41-4B); a 1.4 Mb duplication of chromosome 17p12 accounts for greater than half of all adult-onset forms of inherited Charcot-Marie-Tooth (CMT) neuropathies (Fig. 41-4C and D). Evidence suggests that ectopic crossovers that lead to NAHR are preceded by an ectopic synapsis. Nonrecurrent rearrangements are of variable sizes with different breakpoint junctions in each patient reflecting distinct mechanisms of formation that include nonhomologous end joining (NHEJ) and replicative mechanisms such as FoSTeS (fork stalling and template switching) and MMBIR (microhomology-mediated break-induced replication). Whereas most recurrent rearrangements are typically "simple," a significant fraction of nonrecurrent genomic rearrangements with two or more breakpoint junctions referred to as *complex genomic rearrangements* (CGRs) have been implicated in causation of human disease phenotypes (Fig. 41-4E). These CGRs often occur as de novo events, vary in size from those involving a single exon to megabases of genomic sequence, and typically involve loss (i.e., deletion) and/or gain (i.e., duplication, triplication, etc.) in a single or multiple gene loci.[9] An extreme example of CGRs is a chromosome catastrophe wherein several copy-number changes and multiple breakpoints are concentrated on a single chromosome. This phenomenon, termed *chromothripsis*, has been noted in about 3% of all cancers and up to 25% of bone cancers and may portend a more severe disease.[10]

Balanced reciprocal translocations result from an exchange of the DNA material between two chromosomes and are found in about 1 in 600 individuals. During meiosis, the translocation chromosomes form a pachytene tetrad structure, and depending on the segregation type (alternate or adjacent, symmetrical or asymmetrical), either balanced or unbalanced products are transmitted to progeny. The unbalanced products often lead to either spontaneous miscarriage or birth of a child with significant clinical consequences. Recently, it has been shown by high-resolution genome analyses that up to 40% of apparently balanced translocations found in subjects with abnormal phenotypes are associated with additional imbalances at or near the translocation breakpoint or elsewhere in the genome.

Translocations involving short arms (or centromeres) of acrocentric chromosomes are described as *Robertsonian translocations*. Balanced Robertsonian translocations (45 chromosome complement) are present in 1 in 900 newborns and are thus the most common chromosome rearrangements in humans. The most frequent Robertsonian translocation, t(13;14), is found in 1 in 1300 individuals. The carriers of balanced Robertsonian translocations have a significantly increased risk for an unbalanced karyotype in progeny (e.g. trisomy 21 or trisomy 13) or uniparental disomy for chromosomes 14 and 15 that are known to contain imprinted genes.

Constitutional non-Robertsonian chromosomal translocations are nonrecurrent with the exception of three recurrent translocations: t(11;22)(q11.2;q23.3), which utilize AT-rich cruciforms, and t(4;8)(p16;p23) and t(4;11)(p16;p15.2), which are mediated by low-copy repeat gene clusters.

When a fragment of one chromosome is translocated into another chromosome's arm, the aberration is termed an *insertion* or *insertional translocation*. Insertional translocations have been recently shown by high-resolution human genome analyses to occur more than 100 times more frequently than recognized previously. The carrier of a balanced insertion has up to a 50% chance of an abnormal offspring.

An *inversion* is defined as a chromosome fragment that is reversed end to end. Inversions harboring the centromere are termed *pericentric*, and those with breakpoints mapping in the same chromosome arm are termed *paracentric*. Usually, only the products of pericentric inversions (unbalanced terminal deletion of one chromosome arm accompanied by a terminal duplication of the second arm) are found in a progeny. The acentric or dicentric products of paracentric inversions are unstable and thus not transmitted.

Other less common structural chromosomal abnormalities include ring chromosomes, isochromosomes, complex chromosome rearrangements, and heterochromatin variants. Rings arise when two broken ends of the same chromosome fuse. Usually, chromosome material telomeric to the breakpoints is lost and leads to an abnormal phenotype. Rings are commonly unstable mitotically and often form double ring structures. Isochromosomes arise when one part of the chromosome is duplicated and separated from the other. Isochromosomes can be monocentric (breakpoint in the centromere) or dicentric and thus unstable unless one of the centromeres becomes inactivated (pseudoisodicentric).

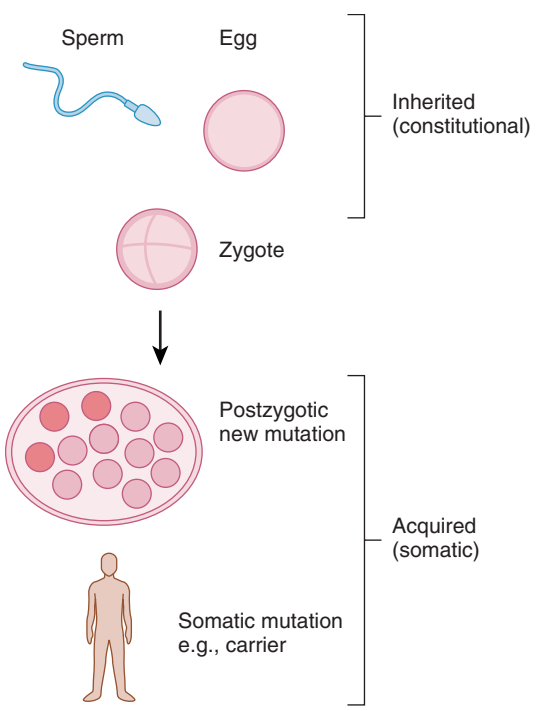

FIGURE 41-5. Mutation. Constitutional mutations are inherited from one of the parents. They can be present in the somatic cells of a parent (carrier) or can arise during gametogenesis (de novo). Mutations that occur postzygotically (acquired, somatic) are usually found in a mosaic state.

Mosaicism and Chimeras

The presence of two or more cell lines with different chromosome complements in one individual is termed *mosaicism* when they originate from the same zygote or *chimeras* when the cells originate from different zygotes. Chromosomal mosaicism is a common phenomenon and is observed in about 50% of embryos at the eight-cell stage and up to 75% of blastocysts. Somatic chromosomal mosaicism is found, for example, in patients with hypomelanosis of Ito and Pallister-Killian syndrome (tetrasomy 12p). Genome mosaicism in an organism may be more prevalent than appreciated and can be responsible for disease.[11]

MUTATIONS

Mutation is defined as a change in nucleotide sequence due to errors of DNA replication, recombination, repair, or radiation, chemical mutagens, viruses, or transposons. Gene mutations can be inherited from a parent (hereditary, constitutional, or *germline mutations*) and thus present in every cell or can be acquired in some tissues during development or any time throughout a person's life (*somatic mutations*) (Fig. 41-5). Whole genome sequencing of lung cancer tissue suggests one new point mutation for every pack of cigarettes smoked. Point mutations, usually involving only one or a few nucleotides, have been divided into substitutions, insertions, and deletions. Mutations mapping in protein-coding sequences and changing the protein structure have been termed *nonsynonymous,* whereas those that do not lead to protein change are known as *synonymous* or silent mutations. The latter mutations can still have functional consequences, for example, by generating a cryptic splice site, an exon splice enhancer, or affecting the regulatory elements.

Based on the functional consequences, mutations have been divided into loss-of-function and gain-of-function mutations. The former, also known as *hypomorphic* (partial loss) or *amorphic* or *null* (complete loss), affect the dosage-sensitive or haploinsufficient genes, in which a decreased amount of protein is not sufficient for normal function. Gain-of-function mutations increase or add a new function for the protein (*neomorphic*), whereas dominant negative mutations encode a protein that interacts antagonistically with the normal product from the other allele (*antimorphic*).

The situation in which one allele is mutated and the second is normal (wild-type) is referred to as *heterozygous*. A combination of the same two mutations in each of the alleles of the same locus (e.g., in consanguineous families) is defined as *homozygous*, or *compound heterozygous* when the two mutant alleles are distinct. Two mutant alleles at different loci are described

as *double heterozygous*. When one of the alleles is absent (e.g., because of a deletion CNV or for most of the X chromosome genes in males), the locus is referred to as *hemizygous*.

Different mutations in one gene can manifest with the same or distinct phenotypes, phenomena called *allelic heterogeneity* or *allelic affinity*, respectively. By contrast, the same abnormal clinical phenotype can be caused by mutations in different genes (*genetic* or *locus heterogeneity*).

Single Nucleotide Variants

Nonsynonymous mutations can either lead to a single amino acid change (*missense*), alter the reading frame leading to alteration in the downstream protein structure (*frameshift*), introduce a stop codon (*premature termination codon* [PTC]) that truncates the protein prematurely (*nonsense*), or abolish the specific site at which splicing of an intron takes place during the processing of precursor mRNA into mature mRNA (splice site). The PTC mutated mRNAs are inactivated and removed from cells by a surveillance mechanism called *nonsense mediated decay* (NMD) that is initiated by a premature termination codon in any exon except the last and a 50- to 55-bp portion of the second to last (i.e., penultimate) exon that usually escape NMD.

Transition mutations refer to changes from pyrimidine to pyrimidine (e.g., C to T) or purine to purine (e.g., A to G) bases and are more frequent than transversions, which are exchanges from purine to pyrimidine (e.g., A to C) or pyrimidine to purine (e.g., T to G) bases. The most common transition, C to T, is about 10-fold more common than other base changes and occurs in the methylated CpG dinucleotide because methylated C can be deaminated and converted to T (see Fig. 41-2).

Unstable Repeat Expansions

Mutations that are unstable have been termed *dynamic*. Pathogenic dynamic expansion of trinucleotide, tetranucleotide, and pentanucleotide repeat sequences can be located in coding (e.g., CAG triplet in Huntington disease) or noncoding regions such as introns (e.g., GAA in Friedreich ataxia), or untranslated regions, either 5′ (e.g., CGG in fragile X syndrome) or 3′ (e.g., CTG in myotonic dystrophy). The mutations convey phenotypes that can be inherited as autosomal dominant (e.g., myotonic dystrophy), autosomal recessive (e.g., Friedreich ataxia), or X-linked (e.g., fragile X syndrome) traits due to gain or loss of function of the encoded protein. For each of the dynamic mutation diseases, there is a specific repeat number limit, above which the disease is manifested. The number of repeats below that threshold but greater than normal is referred to as a *premutation*. However, in some "disease genes," premutations are also associated with a milder, later onset, and sometimes distinct phenotype (e.g., ovarian failure in females and late-onset neurologic disorders in males with premutations in the fragile X syndrome *FMR1* gene). The number of repeats tends to expand in the next generations, a phenomenon called *anticipation*; this typically occurs in a sex-specific manner.

Copy-Number Variants

The Watson-Crick DNA base-pair changes are not the only mutational mechanism responsible for Mendelian monogenic diseases and complex traits. Higher order genomic architectural features can lead to a regional intrinsic instability of the human genome and susceptibility to DNA rearrangements, that is, CNVs that can be a frequent cause of diseases in humans. Such conditions that result from structural genome changes or CNVs have been referred to as *genomic disorders*.

A major mechanism by which rearrangements convey phenotypes is alteration of gene dosage because of a variation in gene copy-number. CNVs can lead to deletion, duplication, or disruption of the dosage-sensitive gene, generate gene fusions, exert position effects, or unmask mutations in the coding region or other functional SNPs in the second allele, as when a deletion CNV results in a hemizygous state.

Different calculations have shown that the de novo locus-specific mutation rates for genomic rearrangements are between 10^{-4} and 10^{-5}, at least 1000 to 10,000 fold more frequent than de novo point mutations. Thus, new-mutation CNV can contribute significantly to sporadic disease[12], including various common human neurodevelopmental conditions such as schizophrenia, autism, and intellectual disability, as well as sporadic cases of rare Mendelian disorders.[13]

Many genomic disorders occur sporadically and are often caused by de novo rearrangements. Recurrent rearrangements (deletions, duplications, or inversions) are caused by NAHR between low-copy repeats that are located less than 5 to 10 Mb from each other and have greater than 97% DNA sequence identity. The fixed position of these low-copy repeats or segmental duplications in the human genome result in recurrent rearrangements having a common size for a given region. NAHR between directly oriented low-copy repeats leads to deletions or reciprocal duplications of the genomic region located between them, whereas NAHR between the oppositely oriented low-copy repeats results in an inversion of the intervening genomic segment. Interestingly, the strand exchanges for NAHR sites are not scattered throughout the entire length of homology within low-copy repeats but instead cluster in recombination hotspots.

Most nonrecurrent CNVs appear to occur by nonhomologous recombination mechanisms, and one often observes microhomology at the breakpoints. The remainder of nonrecurrent different-sized rearrangements likely result from a NHEJ recombination mechanism. One prominent mechanism, particularly for complex (e.g., deletion/normal/duplication) rearrangements is the microhomology-mediated break-induced replication (MMBIR) mechanism.

Microduplication and Microdeletion Syndromes

Some of the microduplication and microdeletion syndromes are caused by a copy-number change of the dosage-sensitive or haploinsufficient gene. Among the best characterized genomic disorders are common autosomal dominant peripheral neuropathies, CMT1A and hereditary neuropathy with liability to pressure palsies (HNPP), that are caused by duplication and deletion CNV, respectively, of an about 1.4 Mb genomic interval within 17p12 harboring a dosage sensitive myelin gene *PMP22*. This genomic segment is flanked by two approximately 24 kb and 98.7% identical LCRs, termed the *proximal* CMT1A-REP and the *distal* CMT1A-REP, which serve as substrates for NAHR. Another example of common predominantly monogenic reciprocal microdeletion/microduplication syndromes is Potocki-Lupski syndrome, which can present clinically as autism and occurs due to dup(17)(p11.2p11.2), the recombination reciprocal to del(17)(p11.2p11.2) found in patients with Smith-Magenis syndrome. When two or more dosage-sensitive genes that are usually functionally unrelated are involved, these are referred to as contiguous gene deletion or duplication syndromes, for example, Potocki-Shaffer syndrome resulting from deletion del(11)(p11.2p11.2). LCR-mediated recurrent microdeletion and microduplication syndromes usually have similar prevalence in different populations; however, for a few genomic disorders, significant differences in incidences in different world populations have been observed, likely demonstrating that variation of genomic architecture is a significant factor for disease susceptibility (e.g., 17q21.31 microdeletion syndrome, Sotos syndrome, and 5q35). Examples of well-known and characterized microdeletion syndromes include Williams-Beuren syndrome (7q11.23), Prader-Willi and Angelman syndromes (15q11.2q12), DiGeorge syndrome (22q11.2), microdeletion 17q21.31 syndrome, microdeletion 1q21.1 syndrome, and Sotos syndrome. For all these microdeletions, the reciprocal microduplications predicted by the NAHR model have been reported, with phenotypes typically being milder. Whereas the role of CNVs in the causation of disorders like the aforementioned syndromes has been known for a while, recent studies have shown that a proportion of patients with neuropsychiatric manifestations including autism and schizophrenia harbor CNVs involving specific loci (e.g., 1q21.1, 15q13.3, and 16p11.2).[13] It is now becoming apparent that CNVs may be important for the some of the complex human traits.

PATTERNS OF INHERITANCE

Mendelian Inheritance

Most characterized disease-associated mutations in humans can be assigned to a single gene (monogenic) or locus and segregate as a Mendelian trait in an autosomal dominant, autosomal recessive, or X-linked fashion.

Autosomal dominant mutation is present in only one allele and thus is transmitted in meiosis to 50% of the gametes and is expected to manifest in half the offspring unless the trait is incompletely penetrant (e.g., in BRCA-related breast and ovarian cancer), represents variable expressivity (e.g., in Marfan syndrome), is age dependent (e.g., in Huntington disease), or is lethal (e.g., alveolar capillary dysplasia). In pedigree analysis, autosomal dominant inheritance is revealed as a vertical transmission of the trait.

In an autosomal recessive trait, the affected individuals carry two mutant alleles at a specific locus that are either the same (homozygous) or different (compound heterozygous). In general, both mutations are inherited from unaffected carrier parents (but note that occasionally heterozygous carriers of the mutated allele may manifest a mild phenotype or have an increased susceptibility to complex or multifactorial traits). Theoretically, affected

probands represent 25% of the progeny; one half of the unaffected siblings carry one mutated allele, and the remaining one fourth of all progeny (one third of unaffected) have two wild-type (normal) alleles. In pedigree analysis, autosomal recessive inheritance is observed as horizontal transmission of the trait.

In X-linked (both dominant and recessive) diseases, no male-to-male transmission is observed, and all daughters of affected fathers are obligate carriers of the mutated allele. X-linked dominant diseases are more rare than X-linked recessive disorders and present both in males and in females. Usually, there are twice as many affected females as males; however, if the disease is lethal in males, only females are affected (e.g., Rett syndrome). Because of X inactivation, the phenotype in females is milder than in males in X-linked dominant diseases. In an X-linked recessive trait, only males are affected; in female carriers, the X chromosome harboring a mutated recessive allele is preferentially inactivated by nonrandom X inactivation. However, females with an incomplete or skewed X inactivation, females with only one X chromosome (Turner syndrome), or females carrying a balanced translocation between the X chromosome and an autosome (X material on the derivative chromosomes is not inactivated) can manifest the X-linked recessive disease.

Non-Mendelian Inheritance

The occurrence of sporadic cases of the disease can be explained by a classic Mendelian inheritance, such as de novo autosomal dominant, autosomal recessive, or X-linked mutation. However, one has to consider other possibilities, including non-Mendelian inheritance—genomic imprinting, uniparental disomy, mosaicism, mitochondrial DNA mutations, and digenic or triallelic inheritance.

Some genes acquire different activity status (usually methylation) after passage through spermatogenesis compared with oogenesis. As a result, a gene can be silenced (*imprinted*) depending on the parent of origin. This parent-of-origin effect is observed for the *UBE3A* gene on chromosome 15q12 that is imprinted during spermatogenesis, and only the maternal copy is active. When the active maternal copy of *UBE3A* is mutated, deleted, or inactivated in a different way, the offspring is affected with Angelman syndrome.

Sporadically, a chromosome pair may not be inherited from both parents. This distortion from biparental inheritance, termed *uniparental disomy* (UPD), may have clinical consequences when the uniparental chromosomes contain an autosomal recessive mutation or an imprinted gene. When both homologues are inherited from one parent, it is referred as *heterodisomy*. In *isodisomy*, both homologues in an offspring originate from only one of the parental homologues. The most frequent mechanism for UPD is trisomy rescue, in which an early postzygotic embryo is trisomic as a result of chromosome nondisjunction in meiosis I, and the extra chromosome is then lost during further development to restore disomy. Because this is a random event, in one third of cases, the disomic chromosomes remaining after trisomy to disomy rescue will represent UPD. Consequently, UPD is associated with advanced maternal age.

In some diseases, pathogenic mutations have been found in single alleles of two different genes with the other alleles at each given locus being normal. This double heterozygous phenomenon of two interacting genes has been reported, for example, for *ROM1* and *RDS* in retinitis pigmentosa and *GJB6* and *GJB2* in deafness.

In some patients, three abnormal alleles in two different genes have been identified. The phenomenon of triallelic (or oligogenic) inheritance has been observed, for example, in Bardet-Biedl syndrome, familial hypercholesterolemia, and cortisone reductase deficiency. Monogenic chromosomal microduplication syndromes (e.g., Charcot-Marie-Tooth type 1A) can also be categorized as triallelic given the presence of three alleles at a given locus because of duplication CNV.

Another distortion from Mendelian inheritance can be caused by mosaicism. Two or more cell lines can be present either in the gonads only (germline mosaicism) or in somatic cells. Mosaicism should be suspected when healthy parents have two or more children with a dominant disease. Mosaicism can be particularly relevant when mutational processes involve DNA replication errors and occur mitotically (e.g., point mutation and MMBIR).

Very rarely, a disease trait is transmitted to daughters and sons only from mothers. In such cases, one should consider a mitochondrial disease due to mutations in mitochondrial DNA (mtDNA). Multiple copies of mtDNA are present in the cell cytoplasm and are transmitted to progeny only through the oocytes. Initial clinical signs and symptoms typically originate from the most energy-dependent tissues (e.g., eyes, brain, skeletal muscle, and heart), and the phenotypic expression among family members varies and depends mainly on the proportion of mtDNA in the cytoplasm that carries the mutation, that is, *heteroplasmy*.

ASSAYING GENETIC VARIATION

Chromosome aberrations larger than about 5 Mb can be detected by light microscopy after specific staining that reveals characteristic banding patterns (e.g., G-banded karyotype analysis). Submicroscopic rearrangements, such as microdeletions or microduplications (30 kb to 5 Mb), have been analyzed previously using molecular cytogenetic techniques such as fluorescence in situ hybridization. In these routine clinical cytogenetic techniques, usually subpopulations of peripheral blood T lymphocytes stimulated by phytohemagglutinin are analyzed. Rearrangements of similar size (30 kb to 5 Mb) can be analyzed also using pulsed-field gel electrophoresis. However, both of these technologies are limited to the analysis of specific genomic regions, that is, locus-specific testing.

The development of array-based comparative genomic hybridization (array CGH) has enabled screening of the entire human genome for imbalances, with the level of genome resolution depending only on the number, size, and distance between the arrayed interrogating probes. These genome-wide imaging techniques are analogous to digital photography wherein the resolution observed is dependent on the pixels used. Initial clinical array CGH used large genomic clones, BACs and PACs (bacterial or P1 artificial chromosomes), as interrogating probes. These were rapidly replaced by oligonucleotides, of which millions can be synthesized on one glass slide. Oligonucleotide probes are also used on SNP arrays, which, in contrast to microarray-based CGH, enable association studies or detection of uniparental disomies. The widespread use of array CGH for diagnostic purposes not only has increased the sensitivity in detecting CNV associated with disease but also has led to the discovery of many new genomic disorders.

For detection of genomic imbalances, an alternative quantitative polymerase chain reaction–based technique, multiplex ligation-dependent probe amplification (MLPA), has been developed. MLPA is an inexpensive, simple, rapid, and sensitive tool to detect dosage alterations in selected genomic regions.

Most recently, several next-generation sequencing (NGS) technologies have been developed that enable simultaneous and massively parallel DNA sequencing. Such technologies have ushered in the era of "panel testing" (simultaneous assay of multiple genes implicated in a particular phenotype), whole exome sequencing (sequencing the entire coding regions of the genome), and whole genome sequencing (sequencing of the entire genome of an individual). In NGS, DNA sequencing uses chemistries other than the traditional Sanger dideoxy chain termination method. NGS methods generate far larger quantities of data at less expense; however, the individual raw sequence reads that are generated from individual amplified DNA template sequences have shorter read lengths and lower quality. Nevertheless, massive redundant sequencing of a personal diploid human genome (e.g., 30-fold coverage with respect to the haploid human reference genome sequence) provides robust and accurate personal genome sequencing. The NGS technologies have led to an explosion in gene discovery and understanding of the mechanistic bases of genetic disorders.[14] The use of whole exome sequencing alone for clinical diagnosis at the present time has resulted in a diagnostic yield of about 25%, a significant improvement over the currently available testing modalities.[15] NGS technologies have also made it possible to amplify cell-free DNA from maternal serum to facilitate prenatal screening for trisomies involving chromosomes 13, 18, or 21.

Recent advances and the relatively widespread use of array CGH and NGS technologies have transformed our understanding and diagnosis of human disease. With decreasing costs of sequencing and more extensive use of these methodologies, our understanding of the human history, evolution, disease, and treatment will inevitably advance to new levels of sophistication.

CONCLUSION

Mutations in humans are caused by SNVs and CNVs. New mutations can contribute to sporadic disease. The total genomic load can be important to clinical phenotype. Individual genetic variation is extensive. It is a sobering thought that for about 80 to 90% of the annotated genes in the reference human genome, a function remains to be elucidated for the potential clinical consequences of mutations. Furthermore, 98% of the human genome is noncoding, and the functional consequences of variation within it cannot be deciphered using the genetic code.

REVIEW QUESTIONS

1. Which of the following genic regions is protein coding, i.e., translated into a polypeptide?

A. Introns
B. Micro-RNAs
C. Small nucleolar RNAs
D. Long noncoding RNAs
E. Exons

Answer: E Only 1 to 2% of the genome consists of sequences that encode proteins. These protein-coding genic regions have exons and introns that are transcribed into messenger RNA (mRNA). However, only the exonic regions code for the amino acid sequences in the protein, and thus, the intervening intronic sequences are spliced out from the mature mRNA before translation. Micro-RNAs, small nucleolar RNAs, and long noncoding RNAs are transcribed but not translated; nevertheless, they are involved in many important biologic processes. (See Gene.)

2. Which of the following genetic variations in humans involves a change in a single base pair?

A. Copy-number variants
B. Single nucleotide polymorphism (SNP)
C. Inversion
D. Microsatellite
E. Repetitive element

Answer: B Genetic diversity in humans can be due to variations in single nucleotides (e.g., SNP), copy-number (e.g., duplications, triplications), copy-neutral changes (e.g., inversions, absence of heterozygosity), microsatellites (e.g., short tandem repeats), and repetitive elements. Single nucleotide changes that have allelic frequency of more than 1% are termed *single nucleotide polymorphisms*. These SNPs have been used in association studies that have tried to assess whether particular alleles confer a higher risk for common disorders like diabetes. (See Genetic and Genomic Variation in Humans.)

3. Which of these diagnostic techniques cannot be used to detect deletions or duplications involving one or more genes?

A. Sanger sequencing of genomic region of interest
B. Array comparative genomic hybridization (aCGH)
C. Multiplex ligation-dependent probe amplification (MLPA)
D. Fluorescence in situ hybridization (FISH)
E. SNP array

Answer: A Copy-number variations that include deletions or duplications can cause many human phenotypes. Sanger sequencing that involves amplification of specific regions of the genome followed by reading of the sequence typically cannot detect such copy-number changes. Molecular cytogenetic techniques that assess copy-number such as aCGH and SNP arrays (at the whole genome level) or FISH and MLPA (at specific regions of interest) should be employed in diagnosis of such deletions or duplications. (See Assaying Genetic Variation).

4. Two sisters and their brother who are affected with a severe form of neurologic disease presenting with structural brain malformation, intellectual disability, and behavioral abnormalities are evaluated for a genetic diagnosis. The parents and another sibling are asymptomatic and have no medical problems. A detailed family history shows no other members affected with a similar condition. Physical examination, laboratory tests, and imaging techniques do not point to any specific diagnosis. Which of these testing modalities is likely to be most useful in evaluation of this family?

A. Array comparative genomic hybridization (aCGH)
B. SNP array
C. Whole exome sequencing (WES)
D. Assaying for unstable repeat expansion
E. High-resolution G-banded karyotyping

Answer: C Multiple affected individuals in the same generation without other family members being affected is most suggestive of an autosomal recessive disease. When the clinical phenotype is not distinct to narrow down the putative genes, WES is the diagnostic test most likely to provide a molecular confirmation. (See Assaying Genetic Variation).

5. A 50-year-old man presents with early-onset diabetes, hearing loss, muscle weakness, and stroke-like episodes. His brother, mother, two maternal uncles, maternal grandmother, and others have a history of a similar condition. Review of the extended pedigree shows no male-to-progeny transmission. With which molecular mechanism would this be most consistent?

A. Autosomal dominant mutation that results in haploinsufficiency
B. Autosomal dominant mutation that confers neomorphic property
C. Autosomal dominant mutation that confers antimorphic property
D. Mitochondrial DNA mutation
E. Copy-number variants

Answer: D Whereas all the mutations mentioned can present with multiple members across generations being affected, the transmission of disease to progeny only through females is classic for mitochondrial DNA mutations. The phenotypic manifestations in individuals can vary based on the load of mutant mitochondrial DNA (heteroplasmy). (See Patterns of Inheritance.)

THE INHERITED BASIS OF COMMON DISEASES

SEKAR KATHIRESAN AND DAVID ALTSHULER

A central question in medicine is to understand why some people get sick and others do not. We seek these answers for multiple reasons: to provide explanations to our patients, to predict disease risk early enough to prevent it, and most important, to understand pathophysiology so as to design rational approaches to prevention and therapy. In some cases, a single environmental exposure is found to play a major role in disease (e.g., smoking and lung cancer, or HIV infection and AIDS). In others, such as Huntington disease or cystic fibrosis, mutation of a single gene is both necessary and sufficient to cause illness. Of course, singular answers are the exception rather than the rule; in most cases, disease arises from the combined action of inborn and somatically acquired alterations in genome sequence, environmental and behavioral exposures, and bad luck. Such disorders, which explain most morbidity and mortality in human populations, are termed *complex traits*.[1]

As a tool for generating new hypotheses about the root causes of disease, human genetics has a number of unique features. First, it is now possible to systematically query the entire genome sequence of an individual in a manner unlimited by any prior assumption about underlying genes and pathophysiologic processes responsible. Second, because the constitutional genome sequence is established at conception and unaltered throughout life, associations between genome sequence and human phenotype can be interpreted as causal rather than reactive in their relationship to disease. However, although we have entered an era in which the specific genes and variants that contribute to risk for common human diseases can be identified, much work is needed to understand their functions and to learn whether and how this knowledge can improve the practice of medicine.[2]

HERITABILITY: INHERITED VARIATION IN DISEASE RISK

Susceptibility to disease varies within and across human populations. Studies of *familial aggregation* can determine the extent to which inherited difference in the genome sequence contributes to variation in disease risk. Such studies are simple in concept and ask whether members of the same family are more similar in disease risk compared with individuals chosen at random from the population. Of course, familial clustering can reflect not only shared genotype but also shared environment. The contribution of shared genotype can be dissected further by examining concordance of disease in proportion to the extent of genetic relatedness. The simplest such design involves comparing rates of disease concordance among dizygotic and monozygotic twin pairs. More sophisticated methods have now been developed in which the relatedness of individuals is estimated directly from genotype data (rather than based on pedigrees) and concordance compared with these empirically derived estimates of relatedness. With each of these approaches, common diseases such as types 1 and 2 diabetes mellitus, obesity, hypertension, coronary artery disease, autoimmune diseases, common cancers, schizophrenia, and bipolar disease show rates of disease concordance that rise with genetic similarity. However, many other traits of clinical interest (e.g., most drug responses) have not been studied with these methods, and thus the role of inheritance in these characteristics cannot be assumed. That is, variability in a clinical phenotype (such as drug response) cannot be assumed to be inherited in nature—family studies or molecular genetic studies are needed to draw any such conclusion.

Data about familial aggregation allow the calculation of *heritability*, defined as the fraction of interindividual variability in disease risk attributable to additive genetic influences. In this framework, the remaining variability among individuals is due to the sum of all other contributions to disease risk: environmental influences on disease, nonadditive (*epistatic*) genetic effects (e.g., gene-gene interactions or gene-environment interactions), error in the measurement of relatedness or disease, and random chance. For most clinically important traits (diseases and risk factors), empirical estimates of heritability range from 20 to 80% (see Online Mendelian Inheritance in Man, available at *www.ncbi.nlm.nih.gov:80/entrez/query.fcgi?db=OMIM*, for comprehensive information).

In interpreting estimates of heritability,[3] it is important to consider two crucial factors: the effect of measurement errors and the environmental context. *Measurement errors* decrease the estimate of the observed heritability of a trait. For example, a single measurement of blood pressure is much less heritable than a composite score based on serial measures of blood pressure over time. That is, estimates of heritability are lower bounds because day-to-day variability and imprecision in clinical measures can obscure the underlying biologic susceptibility entrained by inheritance. For the patient and physician, this means that although the blood pressure on a given day may not be particularly heritable, the blood pressure over time (which is the relevant risk factor for vascular disease) is heritable to a greater extent.

Second, estimates of heritability apply only to the context of the environment in which the study was performed. In the case in which environmental triggers of disease are relatively constant across a study population, inherited factors may explain much of the variation in rates of disease. In contrast, in the case in which exposure to environmental causes of disease is highly varied across the study population, nongenetic factors may outweigh the contribution of that same extent of variability in inborn susceptibility. For example, the rate and diversity of smoking behavior have a major impact on how much of the variability in rates of lung cancer (in any given study or patient cohort) is explained by inheritance. If smoking was absent from a given population (or ubiquitous), little of the variation in lung cancer risk would be due to smoking behavior; if, in contrast, half the population smoked multiple packs a day and the other half not at all, smoking behavior would dominate over inborn susceptibility.

For these reasons, heritability is not a fixed characteristic of a given disease but an assessment of a given population, a set of measurements, and the extent to which variability in genetic and environmental exposure explains disease risk. Thus, there is no contradiction between a disease's being highly heritable (in a given population) and yet having rates that vary dramatically across populations separated by time, geography, or socioeconomic status. In broad comparisons across groups, environmental exposure and methods of clinical ascertainment often vary substantially and contribute to secular changes in patterns of disease. Conversely, within a group exposed to a relatively uniform environment and studied in a standardized manner, genetic susceptibility may play a major role in determining individual risk.

HETEROZYGOSITY: INHERITED VARIATION IN GENOME SEQUENCE

Heritability expresses the inherited variation in rates of disease; *heterozygosity* expresses the rate of inherited variation in genome sequences (Table 42-1). Heterozygosity is defined as the proportion of sites on the chromosome at which two randomly chosen copies differ in DNA sequence. Because cells are *diploid* (carry two copies of the genome sequence) and because these two copies were selected in a semirandom manner from the population, heterozygosity is equivalent to the fraction of base pairs that vary between the two copies each of us inherited from our mother and our father. That is, heterozygosity is the rate of genetic variation in the individual.

Single-nucleotide polymorphisms (SNPs) are sites at which a single letter in the DNA code has been swapped for a single alternative letter. Such variants are observed at approximately 1 in 1000 positions in the human genome sequence. In the protein-coding regions of genes, rates of genetic variation are lower—less than 1 in every 2000 bases; the rate of variation that substantially alters the sequence of the encoded protein is lower still (see Table 42-1). The lower rate of variation in coding regions is due to natural selection against alteration in the amino acid sequence of encoded proteins.

Our genomes also contain other types of sequence variation: insertions and deletions of nucleotides; alteration in the number of copies of particular genes and sequences; and larger-scale alterations, such as inversions and translocations. All types of DNA sequence change can influence gene function and contribute to disease.

The genetic variation in each individual is largely attributable to variants that are common. Empirically, more than 98% of the heterozygous sites in each individual display frequency of greater than 1% in the worldwide human population. During the last 15 years, a public database has been built that

TABLE 42-1 CHARACTERISTICS OF HUMAN GENOME SEQUENCE VARIATION

Length of the human genome sequence (base pairs)	3,000,000,000
Number of human genes (estimated)	20,000
Fraction of base pairs that differ between the genome sequences of a human and a chimpanzee	1.3% (1 in 80)
Fraction of base pairs that vary between the genome sequences of any two humans	0.1% (1 in 1000)
Fraction of coding region base pairs that vary in a manner that substantially alters the sequence of the encoded protein	0.2% (1 in 5000)
Number of sequence variants present in each individual as heterozygous sites	3,000,000
Number of amino acid–altering variants present in each individual as heterozygous sites	12,000
Number of sequence variants in any given human population with frequency of >1%	10,000,000
Number of amino acid polymorphisms present in the human genome with a population frequency of >1%	75,000
Fraction of all human heterozygosity attributable to variants with a frequency of >1%	98%

contains essentially all common sequence variants in the human population (with frequency >1%). At the time of this writing, this public database contains more than 44 million human genetic variants (*www.ncbi.nlm.nih.gov:80/SNP/index.html*). Not all these entries represent common variants (some are rare), and a small fraction may represent technical false-positive findings.

The major contribution of common variation in human sequence diversity is explained by the unique demographic history of the human population. Despite the global distribution of the current human population, it is now clear that all humans are the descendants of a single population that lived in Africa only 10,000 to 40,000 years ago. The ancestral population was small (with an effective size of perhaps 10,000 individuals), lived a hunter-gatherer existence at low population densities (relative to other humans and later domesticated animals), and had evolved in Africa during millions of years. Most human genetic variation arose in this phase of human history, before the more recent migrations, expansions, and invention of technologies (e.g., farming) that resulted in widespread population of the globe. Most common human genetic variation predates the Diaspora and is shared by all populations on earth.

A second factor is the slow rate of change in human DNA. Mutation and recombination occur at very low rates, on the order of 10^{-8} per base pair per generation; and yet, any pair of human genes traces a lineage back to a shared ancestor who lived on the order of 10^3 to 10^4 generations ago (if a generation is 20 years, then 10^4 generations is 200,000 years). In other words, considering the typical nucleotide in two unrelated humans, it is more likely that they trace back to a shared ancestor without any mutation having occurred than it is that a mutation has arisen in the intervening time. This explains why 99.9% of base pairs are identical when any two copies of the human genome are compared.

Another aspect of human variation is explained by these simple mathematical and population genetic relationships: the extent of human DNA sequence diversity attributable to rare and common variants. Each of us inherits from our parents some 3 million common polymorphisms (classically defined as those with frequency of >1%). We inherit genetic variants that are shared by apparently unrelated individuals but are at frequencies less than 1%, and we inherit thousands of variants that are limited only to the individual and the individual's closest relatives.

The shared ancestry of human populations explains another aspect of human genetic variation: the correlations among nearby variants known as *linkage disequilibrium.* Empirically, individuals who carry a particular common variant at one site in the genome are observed to be more likely than chance to carry a particular set of variants at nearby positions along the chromosome. That is, not all combinations of nearby variants are observed in the population but rather only a small subset of the possible combinations. These correlations reflect the fact that most variants in our genomes arose once in human history (typically long ago) and did so on an arbitrary but unique copy carried by the individual in whom the mutation first arose. This unique ancestral copy can be recognized in the current population by the stretch of particular alleles (known as a *haplotype*). These ancestral haplotypes, passed down from shared prehistoric ancestors in Africa, offer a practical tool in association studies of human disease because it is not necessary to measure directly each nucleotide to capture much of the information.

THE SEARCH FOR GENES UNDERLYING MONOGENIC DISEASES

The *genetic architecture* of a disease refers to the number and magnitude of genetic risk factors that exist in each patient and their frequencies and interactions in the population. Diseases can be due to a single gene in each family (*monogenic*) or to multiple genes (*polygenic*). It is easiest to identify genetic risk factors when only a single gene is involved and this gene has a large impact on disease in that family. In cases in which a single gene is necessary and sufficient to cause disease, the condition is termed a *mendelian* disorder because the disease tracks perfectly with a mutation (in the family) that obeys Mendel's simple laws of inheritance.

Some single-gene disorders are caused by the same gene in all affected families; for example, cystic fibrosis is always caused by mutations in *CFTR*. Although many individuals with cystic fibrosis carry the same founder mutation (δ-508), others carry any pair of a wide variety of different mutations in *CFTR*. The existence of many different mutations at a given disease gene is known as *allelic heterogeneity.*

A mendelian disorder can be due to a single genetic lesion in any given family but in different families can be due to mutations in a variety of genes. This phenomenon, termed *locus heterogeneity*, is illustrated by retinitis pigmentosa. Although mutation in a single gene is typically necessary and sufficient to cause retinitis pigmentosa, there are dozens of different genes in which retinitis pigmentosa mutations have been found (Online Mendelian Inheritance in Man #268000). In each family, however, only one such gene is mutated to cause disease.

Most single-gene disorders are rare (present in <1% of the population) and are manifested early in life. Many are severe and cause death before reproduction in the absence of modern medical care. The fact that most monogenic disorders are severe in childhood and rare in the population is not a coincidence but reflects the impact of *natural selection.* The deleterious effect of these mutations results in a decrease in reproductive fitness (in individuals unlucky enough to inherit them), and the mutations and the disease are therefore unlikely to drift to high frequency in the population.

There are exceptions to this general idea: cases in which the mutation causing a severe monogenic disease (such as hemoglobin S, the cause of sickle cell anemia) is common in populations. Such cases appear to be the result of a different kind of selection, known as *balancing selection*—situations in which a gene mutation is beneficial in one circumstance (a genotype or environment) but deleterious in another. Heterozygous carriers of hemoglobin S are relatively protected against malaria, and this benefit balances the deleterious effect of sickle cell disease in homozygotes.

Starting in the 1980s, the advent of genome-wide linkage analysis led to rapid success at identifying the specific genetic mutations that cause mendelian disorders, and now thousands of genes have been identified for clinically important conditions (for comprehensive information, see *www.ncbi.nlm.nih.gov:80/entrez/query.fcgi?db=OMIM*). Progress was sparked by the development of a suite of powerful research techniques—*family-based linkage analysis* followed by *positional cloning*—in which a genome-wide search is undertaken for the causal gene, which is first localized to a chromosomal region. (The initial idea of genetic linkage mapping traces to Sturtevant in fruit flies in 1913 but did not become practical in humans until the 1980s.)

Once the search discovered linkage between a chromosomal region and a disease, that chromosomal neighborhood was scoured for the genetic culprit, which was recognized by the observation of mutations that altered the protein-coding sequence, enriched in cases of disease compared with unaffected relatives and population-based controls. The power of these approaches prompted and was fueled by the Human Genome Project, which provided the foundation of information on DNA structure, sequence, and genetic variation required to undertake such searches.

More recently, it has become possible to search for the mutations underlying mendelian diseases by skipping the step of family-based linkage, instead sequencing the genome of the individual and searching for mutations that might explain the disease. If the gene is already known and the mutation easily interpreted (e.g., truncating the protein), this approach is highly efficient and successful. If the gene is rarely mutated and not yet known to cause the disease, or if the mutations are in noncoding regions, direct sequencing still runs up against the analytical and clinical challenge of genome interpretation.

GENETIC INVESTIGATION OF COMMON DISEASES

Similar to mendelian disorders, most common diseases are influenced by inheritance. In contrast to mendelian disorders, the genetic contribution to common diseases is typically due to the action of many genes rather than a single gene in each family. Empirical evidence in favor of this model comes from classical family studies, which failed to observe classical mendelian ratios for common diseases. In the 1990s, the tools of family-based linkage analysis were applied to nearly all common disorders. Much of this work was done in isolated founder populations (such as Finland and Iceland) with the goal of simplifying the genetic architecture and accessing extended pedigrees. Excepting a few notable successes, these studies revealed few strong signals that localized the genes responsible for disease, indicating that few cases of common diseases are due to individual genes of large effect. If a single gene contained rare mutations of large effect that explained 20% or more of the inherited risk for type 2 diabetes, hypertension, or schizophrenia, it would long since have been found with linkage analysis.

The next shortcut to understanding the genetic determinants of common diseases was to identify and study rare families with early-onset forms of common diseases that clearly demonstrate mendelian patterns of inheritance. Important examples include the role of *BRCA1* and *BRCA2* in early-onset breast cancer, maturity-onset diabetes of the young as a form of type 2 diabetes, many monogenic disorders of blood pressure and electrolyte regulation, early-onset Alzheimer disease, and many others.

These successes provide diagnostic information for families burdened with severe, early-onset forms of disease and insight into the underlying pathways responsible for disease. For example, more than 20 genes have been identified that, when mutated, cause rare mendelian disorders of blood pressure and electrolyte regulation. So far, every one of these genes is active in the kidney, and most are involved in the renin-angiotensin-aldosterone pathway. This result is a compelling demonstration of the central importance of the kidney in human blood pressure regulation and has suggested new therapeutic targets of substantial promise.

It was hoped that the genes found to be responsible for early-onset, monogenic forms of common diseases would contribute to the more common forms of disease in the population. In this scenario, severe mutations might cause early-onset forms, and more prevalent but subtle alterations in the same genes might contribute to common forms of disease. A comprehensive test of this hypothesis awaited tools from the Human Genome Project and improved methods of genetic epidemiologic analysis.

ASSOCIATION STUDIES: FROM CANDIDATE GENES TO GENOME-WIDE ASSOCIATION STUDIES

Genome-wide association studies (GWAS) became possible in the mid-2000s on the basis of the sequencing of the human genome, cataloguing of common genetic variants, and high-throughput tools for measuring genetic variation. However, genetic association studies long predated genomic technologies and are simple in concept: the frequency of a common variant is measured in individuals with the disease of interest and compared with well-matched controls (drawn from the population at large or unaffected family members). Now, this process is routinely performed with hundreds of thousands or millions of genetic variants from the genome-wide collection.

Genetic association studies were pioneered in the context of the human leukocyte antigen (HLA) locus on chromosome 6. The HLA complex was discovered on the basis of its role in transplantation tolerance and is characterized by diverse allelic variation that can be measured by interactions of antibodies and antigens. By measurement of these protein-based (immunologic) readouts of the underlying genetic variation, HLA alleles were found to be a major determinant of susceptibility to infectious and autoimmune diseases. Starting in the 1960s, empirical data on human population genetics and genetic association studies were developed in the context of the HLA complex.

By the 1980s, tools of molecular biology made it possible to directly measure DNA variation (rather than using protein or phenotype measurements as surrogates for the underlying genetic variation), ushering in the modern era of human genetic research. In this pregenomic era, it was only practical to measure one or a small number of genetic variations in each study, limiting association studies to incomplete assessments of individual "candidate" genes selected on the basis of biologic criteria.

The study of candidate genes led to a modest number of robust and reproducible associations, such as the contribution of apolipoprotein E4 to Alzheimer disease; factor V Leiden to deep venous thrombosis; a 32-base deletion in the chemokine receptor CCR5 to HIV infection; common variants in the insulin gene to type 1 diabetes; and SNPs in the peroxisome proliferator–activated receptor γ and the β-cell potassium channel Kir6.2 to the risk for type 2 diabetes.

Early in the 2000s, comprehensive surveys of published genetic association studies showed that valid associations were few and far between, with many initial claims of association proving irreproducible, likely representing false-positive claims. One such analysis estimated that in the pre-GWAS era, only 10 to 20 bona fide associations had been documented of common genetic variants with common diseases.

A major reason for the state of this literature was the intrinsically low likelihood of finding a gene and variant contributing to any given disease. Each genome contains millions of genetic variants, and presumably only a small fraction of these influence disease. This is often described as a problem of "multiple hypothesis testing," with the investigative community searching for associations between multiple genes, multiple variants in each gene, and multiple diseases. An alternative (bayesian) statistical framework frames this issue on the basis of low prior probabilities of association. Regardless, it is conceptually clear that much more stringent statistical thresholds (than the traditional $P < .05$) are required for declaring association of genetic variants and disease.

As in linkage analysis for mendelian traits, a key to success in association studies was the advent of genome-wide search, unbiased by prior hypotheses about biologic mechanisms. With the sequencing of the human genome, development of large-scale SNP databases, and tools for genotyping up to one million SNPs per individual, by 2005 it became practical to perform GWAS to identify genomic loci harboring allelic variation. With a recognition that any given variant had a very low likelihood of truly being associated with disease, much more stringent statistical thresholds were deployed (typically requiring a P value of 10^{-7} or lower to declare "genome-wide significance").

Age-related macular degeneration (AMD) provided an early success of GWAS.[4] AMD is a typical common, polygenic disease (Chapter 423); siblings of affected patients are perhaps three to six times as likely as unrelated individuals to become afflicted, and yet family-based linkage analysis revealed only modestly significant (and modestly reproducible) linkage results. The pathophysiologic defects that underlie AMD were largely unknown until it was found that a common coding polymorphism in the gene for complement factor H is a major risk factor for AMD. The variant (*Y402H*) has a high population frequency (approximately 35% in European populations) and increases risk by 2.5- to 3-fold in heterozygotes and by 5- to 7-fold in homozygotes. Multiple other complement factors have since been found to harbor common genetic variation that influences the risk for AMD in a highly reproducible manner, providing unambiguous information about the primary role of complement in this common disease.

Since 2005, GWAS has been used to identify literally hundreds of novel genetic variants that show reproducible associations to a large variety of common human diseases. The field evolved a set of criteria and standards that largely eliminated the previous difficulties with irreproducible claims of association, making association studies a reliable method to identify genomic loci related to human diseases. The National Human Genome Research Institute of the National Institutes of Health maintains a catalogue of GWAS findings (*www.genome.gov/26525384*) that, at the time of this writing, included 12,987 such associations across 1871 publications. This represents dramatic progress compared with the two dozen or so such findings known at the start of the decade.

The results of GWAS support a number of conclusions about the role of common genetic variants in common disease. First, nearly all diseases investigated by GWAS have yielded novel findings, in many cases yielding dozens to more than 100 independent common variants associated with risk of disease. Second, only a small fraction of these findings were previously known, confirming that an unbiased genetic mapping approach can provide new clues about the etiology of common diseases. Third, most of the associations demonstrate modest odds ratios (on the order of 1.1-fold to 1.5-fold), indicating that the genetic nature of common disease is highly polygenic and that natural selection has likely purged alleles of large effect from the pool of common variants. Fourth, in only a few cases (perhaps 10%) does the associated haplotype carry a variant that alters protein structure; this suggests that much of the risk of common disease acts through effects on gene regulation rather

than protein sequences. Fifth, in sum, the variants thus far identified explain only a modest fraction (ranging between 1% and 20%) of the estimated heritability of each disease, indicating that the rest of the inherited risk is due to some combination of common variants of more modest effect, rare variants not yet discovered, nonadditive interactions between genotypes and between genotype and the environment, or other (as yet unanticipated) factors.

Genome-wide approaches (not limited to candidate genes) can be thought of as testing the completeness of the sets of genes previously discovered for each disease by other approaches. For example, in the case of autoimmune diseases, many (perhaps half) of the findings from GWAS lie near a gene previously known to play a role in the immune system. Similarly, a substantial fraction of the genetic variants found to influence lipid levels lie near genes that were previously known to play a role in lipid biology (because they either carry rare mutations that contribute to mendelian forms of hyperlipidemia or were discovered on the basis of laboratory studies).[5] Examples such as autoimmune disease and lipids provide a reassuring alignment of mendelian genetics, biologic investigation, and the genes mapped by GWAS.

However, for the majority of diseases and of disease-associated genetic variants, the genomic regions showing association to disease are novel and do not contain any genes previously studied. One such case is type 2 diabetes, for which more than 80 independent genomic loci have been found to influence risk for disease, and yet only a handful were previously implicated by other methods. A second is myocardial infarction, for which perhaps one third of the SNPs lie near genes involved in low-density lipoprotein cholesterol, but the other two thirds do not contain any previously studied gene. These examples indicate that there are important gaps in our previous knowledge of pathophysiology and biologic mechanisms and that genome-wide approaches can point to high-priority candidates for study.

Although tantalizing, the results of GWAS have raised many more questions than they have answered. Each discovery implicates a particular genomic region, but it has proved challenging to establish which gene is responsible for the association. This is challenging in large part because so many of these common variants are noncoding, and methods to connect noncoding variation to the genes they regulate remain in their infancy. Even where novel genes are identified, much work is needed to discover their biologic and physiologic functions. Finally, GWAS findings explain only a fraction of the estimated heritability of most diseases, leaving open the question of which genes, and which types of variants and genetic effects, explain the remainder.

FROM COMMON VARIANTS TO INDIVIDUAL GENOMES

Although much of human genetic variation is due to common DNA variants (such as those tested through GWAS), each of us also inherits many thousands of variants that arose more recently and that tend to be lower in frequency and more population specific. To the extent that such variants have large effects on phenotype, they might have been previously identified on the basis of family-based linkage studies of mendelian disorders. However, there certainly exists a large universe of lower-frequency variations that have effects too modest to have been recognized and identified in family-based linkage analyses and are too rare to have been captured by the first generation of GWAS.

The study of lower-frequency and rare variants is now practical owing to advances in technology for DNA sequencing. With dramatic drops in price and increases in throughput, it is increasingly routine to sequence individual genomes in the context of medical research (and, in the future, clinical practice).[6] Such an approach will provide a much more complete assessment of genetic variation than was previously obtainable and will incorporate common as well as rare variants—and points to the major challenge of genome interpretation.[7]

For mendelian diseases, the sequencing of individual genomes has made it possible to bypass family-based linkage analysis and positional cloning and instead directly to sequence all protein-coding genes in the genome (so-called exome sequencing) among affected and unaffected individuals. Since 2009, the use of exome sequencing has led to the identification of numerous genes for mendelian disorders that had proved intractable with previous methods. For example, we studied a family in whom four siblings displayed extremely low blood low-density lipoprotein cholesterol, high-density lipoprotein cholesterol, and triglyceride levels—an apparently recessive disorder termed familial combined hypolipidemia. Previous linkage studies had identified a chromosomal region in which the causal gene lay, but because of the prohibitively large number of genes in the region, causal mutations had not been found. Exome sequencing of DNA samples from two of the siblings revealed only one gene, angiopoietin-like 3 (*ANGPTL3*), that harbored rare DNA variants in both alleles in both siblings.[8] Subsequent studies confirmed the presence of additional *ANGPTL3* mutations in unrelated individuals with the same disease.

For common diseases, elucidation of the role of low-frequency and rare variants is just beginning. At the time of this writing, initial genome sequencing studies of hundreds or a thousand cases of common diseases (compared with appropriate controls) have yielded few findings. This is likely due to some combination of (1) the causal rare variants being lower in frequency and more modest in effect size (that is, not deterministic) and thus requiring large samples to achieve statistical significance; (2) the current limitations in our ability to recognize functional mutations from the sea of benign DNA variants, which is needed to increase signal compared with noise; (3) the need for improved statistical methods for relating rare variants to disease; and (4) the natural selection during human evolution, which shaped the overall balance of rare and common variants that contribute to each disease.

CLINICAL IMPACT: PREDICTION, PREVENTION, AND DRUG TARGETS

Much has been written about the future use of genetic prediction in clinical medicine, but a sober appraisal requires consideration of the natural history of each disease, the available approaches for presymptomatic prevention, and the predictive nature of each test. Where genetic prediction is strong, disease outcomes are serious, and prevention exists, the combination can be of great clinical value. For example, in hemochromatosis, knowledge of genetic risk and measurement of iron stores allow presymptomatic phlebotomy, a safe and effective approach that reduces the development of end-organ damage and that would otherwise not be used. Similarly, testing for *BRCA* mutations in at-risk individuals provides valuable information about cancer risk, allowing women to choose between intensive monitoring and preventive surgery (mastectomy and oophorectomy) to reduce risk of cancer. What these examples share is that the disease is relatively rare, a robustly measured genetic risk factor dramatically increases risk, and an established prevention exists that otherwise (because of cost, convenience, or risk) would not be used.

For most common diseases, the role of genetic prediction remains unclear. This is because the disease is common, and genetic risk (as we understand it today) is probabilistic rather than deterministic in nature. Thus, the discrimination in risk due to genetics is much more limited. Moreover, in many cases, it is the characteristic of available interventions (rather than the genetic test per se) that limits utility. For example, some prevention strategies, such as diet and lifestyle modification for type 2 diabetes, are useful for everyone. In such settings, identification of a high-risk population is either of limited use or could even be counterproductive (if a focus on high-risk individuals ended up denying the rest of the population a worthwhile and safe prevention strategy). In other cases, we simply lack a proven preventive intervention, and thus risk estimation alone is not what limits progress. For example, the genetics of AMD has identified common variants with substantial effects on risk and a cumulative score of such variants that can stratify risk in the population by dozens-fold. However, at present, prevention for AMD involves smoking cessation, diet, and exercise, all of which are best deployed widely in the population rather than in a targeted manner.

To realize the value of genetic insights into disease, it will be necessary to develop new and more effective approaches to prevention that target causal mechanisms. One encouraging example involves the gene encoding proprotein convertase subtilisin/kexin type 9 (*PCSK9*) and risk of myocardial infarction. Mutations in *PCSK9* were first identified through genetic mapping studies of rare families with very high levels of low-density lipoprotein cholesterol. Soon, candidate gene association studies of *PCSK9* revealed the existence of common variants that reduced or eliminated the function of the *PCSK9* protein; in one study, 2.6% of African Americans carried nonsense mutations in *PCSK9*. These "loss of function" variants in *PCSK9*, being common, could be studied in large populations for impact on clinical phenotypes and were soon shown to reduce plasma low-density lipoprotein cholesterol and to protect against coronary heart disease. This indicated that reduction in *PSCK9* function would be expected to reduce risk of myocardial infarction through its effects on low-density lipoprotein cholesterol. Moreover, a small number of people were found to be homozygous for these loss-of-function *PCSK9* mutations and, despite lacking immunoreactive *PCSK9* protein, to be healthy and well. This indicated that even complete reduction in risk of *PSCK9* would likely be safe.

On the basis of these results, several companies have developed monoclonal antibody–based drugs targeting the *PCSK9* protein.[9] Preliminary data

from clinical trials of these agents have demonstrated large reductions in blood low-density lipoprotein cholesterol levels, in some cases surpassing even the most potent statin drugs. A reduction in risk of myocardial infarction is predicted on the basis of the genetic data for loss-of-function *PCSK9* mutations as well as the experience with other drugs that lower low-density lipoprotein cholesterol. However, definitive outcomes trials remain important and, at the time of this writing, have not yet been completed.

IMPLICATIONS AND FUTURE DIRECTIONS

Inherited factors contribute substantially to common as well as to rare diseases. Mendelian disorders are typically caused by rare mutations in the protein-coding regions of genes. On the basis of the results of GWAS, it is clear that common variants play a role in common disease, with typically modest effects that often act through effects on gene regulation rather than on protein structure. Each person carries a deep reservoir of less common and rare genetic variations that will be tested in coming years for a role in disease. It seems reasonable to expect that in the coming decade, systematic and integrative analyses of millions of genome sequences will define lists of genes and variants (both common and rare) that contribute to each human disease. If this international effort incorporates large and epidemiologically valid samples and takes into account factors that could bias results, such as case ascertainment, it should provide reference information needed to annotate each individual genome sequence for disease risk.

However, success in identifying genes and mutations will prove of value only if it leads to improved prediction, diagnosis, understanding, and treatment. Biologic understanding requires bedside-to-bench research, in which genes found mutated in patients are studied in the laboratory. It will be necessary to place new genes into known (and as yet unrecognized) biologic pathways and to understand how dysfunction and dysregulation lead to disease. In some cases, such as the role of complement in AMD (see earlier), initial answers may come quickly; in others, in which the relevant pathobiology is as yet unknown, the information to be gleaned from following these clues is unpredictable. In the fullness of time, genetic insights gleaned from patients should lead to a new generation of therapies that more directly target the underlying root causes of risk in the population.

New approaches to "precision" medicine will require not only development of predictive models and new therapies but also a foundation of clinical trial evidence that demonstrates benefit. That is, it is not sufficient simply to hypothesize that a genetic test or targeted therapy benefits patients, but it will be necessary to test this hypothesis in controlled trials. Such clinical trials will involve measuring DNA variation in study participants and testing approaches to intervention (prevention or treatment) based on such information. Genetic tests may prove predictive without being useful, and only careful research can demonstrate value and justify society's investment in their use.

Whereas much remains uncertain, it is clear that genetic and genomic information is accumulating at a staggering rate and holds much potential as well as challenges for the future of medicine. Rather than leaping to deploy genomics in medicine before value has been shown, it is incumbent on us to carefully develop and critically evaluate the use of this new technology to inform and improve the understanding, prevention, and treatment of disease.

REVIEW QUESTIONS

1. For most common diseases, concordance in disease status is higher in monozygotic twins than in dizygotic twins. This is an example of which phenomenon?

A. Heritability
B. Heterozygosity
C. Epistasis
D. Phenocopy

Answer: A Heritability is the fraction of interindividual variability in disease risk attributable to additive genetic influences. The contribution of shared genotype to a disease can be dissected further by comparing rates of disease within families as a function of the extent of genetic relatedness. The cleanest such design involves the comparison of disease concordance among dizygotic and monozygotic twin pairs. For common diseases such as types 1 and 2 diabetes mellitus, obesity, hypertension, coronary artery disease, autoimmune diseases, common cancers, schizophrenia, and bipolar disease, twin studies have documented that rates of concordance are significantly higher in monozygotic than in dizygotic twin pairs.

2. Heterozygosity is defined as the proportion of sites on the chromosome at which two randomly chosen copies differ in DNA sequence. Most heterozygosity in humans is due to

A. Mutations common in frequency (>1%)
B. Rare mutations (<1%)
C. Mutations private to specific individuals
D. Mutations that lead to loss of protein function

Answer: A The genetic variation in each of us is due largely to common variants. Empirically, more than 98% of the heterozygous sites in each individual display frequency of greater than 1% in the worldwide human population.

3. In cases in which a single gene is necessary and sufficient to cause disease, the condition is termed

A. Mendelian disorder
B. Polygenic condition
C. Phenocopy
D. Allelic heterogeneity
E. Locus heterogeneity

Answer: A In cases in which a single gene is necessary and sufficient to cause disease, the condition is termed a mendelian disorder because the disease tracks perfectly with a mutation (in the family) that obeys Mendel's simple laws of inheritance.

4. Whereas a P value threshold of .05 is considered statistically significant in most of medicine, genome-wide association studies use a P value threshold of $<10^{-7}$ as "genome-wide significance." The principal reason for the more stringent statistical threshold in genome-wide association studies is to

A. Account for multiple testing
B. Account for population stratification
C. Account for potential mismatching of cases and controls
D. Account for technical artifacts

Answer: A Each genome contains millions of genetic variants, and presumably only a small fraction of these influence disease. This is often described as a problem of "multiple hypothesis testing," with the investigative community searching for associations between multiple genes, multiple variants in each gene, and multiple diseases. As a result, much more stringent statistical thresholds (than the traditional $P < .05$) are required for declaring association of genetic variants and disease, and typically $P < 10^{-7}$ is used.

5. Most variants associated with common diseases from genome-wide association studies are of which type?

A. Noncoding variants
B. Missense mutations
C. Loss-of-function mutations
D. Insertion-deletion polymorphisms in coding sequence

Answer: A Most of the associated single-nucleotide polymorphisms from genome-wide association studies lie in noncoding regions, suggesting that they act through effects on gene regulation rather than directly altering protein-coding sequences.

APPLICATION OF MOLECULAR TECHNOLOGIES TO CLINICAL MEDICINE

GEOFFREY S. GINSBURG

The completion of the Human Genome Project more than a decade ago has become an enabler of the systematic exploration of the molecular underpinnings of disease and the expectation that these insights would lead to a transformation of medical practice. Until we were able to probe the molecular architecture of disease using genome technologies, most diseases were defined by anatomic location and clinical symptoms and treated with one-size-fits-all therapies that failed to account for the unique biologic background of the individual. The Human Genome Project laid the foundation for molecular medicine along with advances in genotyping and sequencing technologies, bioinformatics, systems biology, and computational biology. Today, molecular medicine aims to build on this foundation, translating these discoveries into clinical practice, with the ultimate goal of personalized and precision medicine.

MOLECULAR TECHNOLOGIES ALONG THE CONTINUUM FROM HEALTH TO DISEASE

Along the continuum from health to disease (as shown in Fig. 43-1), there are several important points where clinical decision making is now directly influenced and advantaged by molecular technologies (Table 43-1).[1,2] Risk estimates for developing some diseases can be defined during health and possibly even at birth using a variety of DNA analyses. Molecular signatures from technology platforms that measure the expressed genome (RNA, proteins, metabolites) can be used to define physiologic states in response to our environment and predict future clinical outcomes. These approaches also form the basis for a new molecular classification and taxonomy of disease and diagnosis. They can also provide more precise ways to screen for and detect disease at its earliest molecular manifestations, often preclinically. In addition, the selection of certain drugs may now be guided by a patient's underlying genetic makeup as well as the molecular makeup of the disease. Given that a disease's evolution from baseline risk often occurs over many years (see Fig. 43-1), periodic molecular profiling defines a novel form of health care monitoring that focuses on disease prevention and proactive management rather than the current paradigm of acute intervention and crisis response.

GENOMES, DISEASE, AND TREATMENT

A key question in medicine is to what extent genetic variation influences the likelihood of disease onset, affects the natural history of disease in combination with the environment, or provides clues relevant to the management of disease. In addition, it is not just the *human* genome that is relevant to an individual's state of health. The genomes of thousands of microorganisms that constitute *our microbiota* are also relevant to human phenotypes, and insights from *their* genomes are providing new approaches for the diagnosis, study, and treatment of disease (see later).

Sequencing: A Driver of Molecular Medicine

Genome-wide association study (GWAS) debuted in 2005 with the identification of variants in the complement factor H gene as a cause of age-related macular degeneration, (http://www.genome.gov/gwastudies). GWAS has been a transformative approach to identifying common genetic variation across the entire human genome in an unbiased fashion, offering an unprecedented opportunity to uncover new biologic pathways of disease. GWAS has been carried out on large cohorts of patients and controls across numer-

TABLE 43-1 APPLICATION OF MOLECULAR DIAGNOSTICS ALONG THE CONTINUUM FROM HEALTH TO DISEASE: EXAMPLES

TIME POINT IN CLINICAL DECISION MAKING	CANCER		CARDIOVASCULAR DISEASE	
	Test	*Indication*	*Test*	*Indication*
Risk/susceptibility	*BRCA1, BRCA2* *HNPCC* *TP53, PTEN*	Breast Colon Sarcomas	*KIF6, 9p21* Familion five-gene profile	CAD LQTS
Screening	HPV genotypes	Cervical	Corus CAD	CAD
Diagnosis	Cancer Type ID OVA1	Cancer of unknown primary Ovarian mass malignancy	Corus CAD	CAD
Prognosis	Oncotype DX (21-gene assay) MammaPrint (70-gene assay) HER2/neu, ER, PR	Breast	TnI, BNP, CRP	ACS
Pharmacogenomics	HER2/neu *UGT1A1* *KRAS* *EGFR* *ALK* *BRAF* NGS of somatic variation for targeted therapy AmpliChip; DMET *CYP2D6/CYP2C19*	Herceptin Irinotecan Cetuximab Erlotinib, gefitinib Crozotinib Vemurafenib Various (see E-Table 43-1)	*KIF6, SLCO1B1* AmpliChip; DMET *CYP2D6/CYP2C19* *VKORC1*	Statins Various (see E-Table 43-1) Warfarin
Monitoring	CTCs	Tumor recurrence or progression	AlloMap gene profile	Transplant rejection

ACS = acute coronary syndromes; BNP = brain natriuretic peptide; CAD = coronary artery disease; CRP = C-reactive protein; CTCs = circulating tumor cells; ER = estrogen receptor; HPV = human papillomavirus; LQTS = long QT syndrome; NGS = next-generation sequencing; PR = progesterone receptor; TnI = troponin I.
Data from Ginsburg GS, Willard H, eds. *Genomic and Personalized Medicine*. 2nd ed. New York, NY: Academic Press; 2012.

ous traits and diseases, revealing hundreds of common genetic variants associated with those traits.

Since 2001, the cost of sequencing a human genome dropped from $3 billion to less than $10,000. Next-generation sequencing (NGS) technology can now read approximately 250 billion bases in a week and allows direct measurement not just of common variants but also theoretically of *all* variations in a genome. It is estimated that the population frequency of germline variants is approximately 1 in every 1000 of the 3.2 billion nucleotide positions, giving rise to approximately 3 million variants in a given human genome. The challenge lies in figuring out the meaning of variants, many of which occur in noncoding regions (introns) of the genome whose function is largely unknown. Until the significance of the noncoding variants is understood, the focus clinically has been on exome sequencing (which examines variation in the coding sequence of exons that are translated into proteins), where mutations have predictable effects on downstream protein structure. Exome sequencing, which represents only about 1.5% of the 3 billion nucleotides that constitute the human genome, is still less expensive to perform than *whole-genome sequencing*. Individuals typically carry several hundred rare and potentially deleterious coding region variants. The first successful clinical applications of exome sequencing in 2009 revealed the diagnosis of patients with Freeman-Sheldon syndrome, and it is increasingly being explored for clinical applications, including the clinical diagnosis of rare genetic diseases,[3] the selection of cancer treatments based on molecular characterization of the tumor,[4] and the tracking of infectious disease outbreaks in real time[5] (see later).

Genetics of Common Complex Diseases

Despite strong statistical associations linking genetic variants with complex diseases, the low relative risk of the disease alleles (generally <2) limits their use for disease predisposition testing and risk assessment. There are notable exceptions, including genetic variation underlying breast cancer, Lynch syndrome, and celiac disease, where some variants have enabled preventive treatment or screening of family members. Despite these technologic advances in genomics, a simple family history continues to be among the best tools to identify risks for common diseases. In fact, for conditions with high heritability, such as cardiovascular disease, family history is a much stronger predictor of disease than any single or combination of genetic/genomic markers.[6] One model suggests that neither family history nor genetic testing should be used as a standalone but that the real power for disease prediction, risk assessment, and differential diagnosis comes from their combined use.

Clinical Sequencing for Diagnostic Dilemmas

More than 3500 mendelian disorders have a known molecular basis (http://omim.org/). However, there are nearly as many suspected mendelian traits for which the molecular basis remains to be identified. The potential for clinical sequencing to find the underlying cause and identify treatment options for these rare, sometimes debilitating diseases has led to the formation of various large national and international rare disease consortia. In some specialized clinical centers and through programs such as the National Human Genome Research Institute Undiagnosed Diseases Program (http://www.genome.gov/27544402), clinical sequencing is being offered to patients with suspected genetic diseases, the so-called diagnostic dilemmas. Early results from these clinical sequencing programs suggest that the success rate of disease gene identification is about 50%, offering hope for a diagnosis to thousands of individuals with previously undiagnosed or untreated rare disorders.[7]

Newborn Screening, Prenatal Diagnosis, and Preconception Carrier Testing

A natural outcome of identifying genes for rare mendelian disorders is the application of these findings to earlier detection, at birth (newborn screening), in utero (prenatal diagnosis) or before conception (carrier testing). Newborn screening—mandatory, state-supported public health programs meant to protect newborn children by screening them for rare, treatable (and thus preventable) disorders at birth—has been steadily increasing from an average of five conditions in 1995, to a panel of 31 core disorders and 26 secondary disorders currently recommended by the U.S. Department of Health and Human Services.[8] Rapid whole-genome sequencing (about 50 hours from test to result) was recently reported, and because the number of conditions considered for newborn screening will undoubtedly grow, rapid whole-genome sequencing can potentially broaden and foreshorten differential diagnoses, resulting in fewer empirical treatments and faster progression to genetic and prognostic counseling.

Cell-free fetal DNA circulating in maternal blood was isolated, amplified, and sequenced noninvasively through a sample of maternal plasma in 1997, In 2008, NGS technologies were used successfully to identify fetal aneuploidy from cell-free fetal DNA in maternal plasma. Clinical trials of the new method rapidly followed, and by late 2011, noninvasive prenatal testing of trisomy 21 by sequencing of maternal plasma DNA was being offered on a clinical and commercial basis in the United States and China. Noninvasive prenatal testing eliminates the need for invasive procedures, while also greatly expanding the number of genetic variants that have traditionally been detected in utero.[9]

Before conception, carrier screening enables couples to assess their risk for having a child with a recessive mendelian disorder and to use this information to guide their reproductive decisions. There are more than 1000 rare, *recessive* mendelian disorders for which the underlying genetic mutation is known. Although individually rare, these can have a sizable public health impact

considering that each person is estimated to carry on average 2.8 mutations for known severe recessive disorders,[10] and the impact of screening could be substantial in terms of reduced disease morbidity and mortality in the population.

Pharmacogenomics: Germline Genetics Variants and Drug Response

Several genomic markers of efficacy, adverse events, and dosing of therapeutics have been discovered (E-Table 43-1), but their uptake into clinical practice has been variable, despite their clear actionability. In some cases, such as with the *HLA-B*5701* genotype for the HIV drug abacavir and *HLA-B*1502* for the antiseizure drug carbamazepine, carriers of these genotypes should avoid the drug entirely to eliminate a specific serious adverse event. In other cases, such as thiopurine *S*-methyltransferase (*TPMT*) for mercaptopurine or *CYP2C9/VKORC1* for warfarin, adjusting the dose of drug based on genotype can help to avoid toxicity and improve efficacy. *Actionability* is not enough to ensure diffusion of pharmacogenomics testing into clinical practice, as exemplified by the antiplatelet drug clopidogrel, for which despite having a U.S. Food and Drug Administration black box warning for efficacy in individuals carrying the *CYP2C19* genetic variant, there is no clear consensus among physicians on its use. In hepatitis C treatment, on the other hand, the *IL28B* genotype test not only has proved highly predictive of response to pegylated interferon/ribavirin used to treat chronic hepatitis C virus infection but also has seen rapid and widespread adoption in the clinic.[11] Genetic markers that predict reduced therapeutic efficacy may face a high hurdle for established drugs, unless evidence supporting clinical validity and utility of the test is indisputable.

Cancer Pharmacogenomics: Somatic Sequencing of Tumor DNA for Targeting Drug Therapies

Cancer arises as a result of somatic DNA mutations that confer a growth advantage on the cells in which they have occurred, giving rise to tumors. Comparison of the genetic profiles of tumors and the surrounding normal tissue (*gene expression profiling*) can reveal the acquired DNA variation that drives growth and that may reveal targets for treatment.

Targeted Therapies for Cancer

The idea of pairing medicines with specific tumor markers in a targeted fashion became a reality in the mid-1980s when detailed molecular studies of breast tumors led to the discovery of human epidermal growth factor receptor-2 (HER-2), a biomarker overexpressed in approximately 30% of breast tumors and associated with adverse outcomes. Subsequently, trastuzumab (Herceptin), a humanized monoclonal antibody targeting HER-2, was developed in 1998 and was shown to have increased efficacy in patients whose tumors tested positive. HER-2 testing of tumor is now part of the standard work-up and management of breast cancer. In the past decade, other examples of cancer therapies with companion diagnostics have emerged (Table 43-2). For example, *EGFR* mutation testing has markedly improved the efficacy of gefitinib and erlotinib, small molecule drugs for the treatment of non–small cell lung cancer that target *EGFR*. In metastatic colorectal cancer, tumors with mutated *KRAS* are usually resistant to treatment with cetuximab and panitumumab, leading the American Society of Clinical Oncology and the U.S. Food and Drug Administration (FDA) to recommend withholding the drugs in these patients. NGS now allows a comprehensive assessment of actionable tumor markers that indicate the potential for a specific therapeutic to have efficacy in a given tumor (see Table 43-1). In 2011, two cancer drugs received accelerated approval by the FDA for use with a companion diagnostic test: (1) crizotinib for the treatment of patients with locally advanced or metastatic non–small cell lung cancer with its companion diagnostic designed to detect the *EML4-ALK* fusion gene, and (2) vemurafenib for the treatment of patients with metastatic or unresectable melanoma positive for *BRAF* V600E mutations. The International Cancer Genome Consortium (https://www.icgc.org/icgc) and the Cancer Genome Atlas (http://cancergenome.nih.gov/) represent international collaborative efforts to define the spectrum of mutations found in tumors, mapping the genomic landscape of cancer. These efforts will provide a foundation from which to develop additional therapeutic strategies against new targets. However, even when successful, the results may be short-lived as therapeutic resistance evolves. Thus, although NGS is a promising new tool for surveying cancer genomes, it may not be a panacea for cancer genomic medicine.

Microbial Genomes: Friends or Foes?

We can now rapidly sequence the genomes of microorganisms—both the commensal bacteria that regularly inhabit our bodies (the *human microbiome*)[12] as well as the pathogenic infectious agents that cause acute and sometimes fatal diseases.[13] The Human Microbiome Project recently published a study of the microbial populations inhabiting various human body sites[14] and provided reference sequences for many taxa in health individuals as well as their correlation with host characteristics, including ethnicity, age, and body mass index. There are now emerging associations of human microbiota and diseases such as diabetes, asthma, psoriasis, atherosclerosis, and obesity.[15,16] Moreover, strategies to modify the gut microbiome are being explored as treatments for inflammatory bowel disease, including the use of fecal transplantation or engraftment of microbiota from a healthy donor into a recipient.[17] The human microbiome will play an important role in molecular medicine because microbial composition can be altered noninvasively through diet or the use of probiotics or antibiotics.

In infectious disease, diagnosis by NGS may supplant the need to first grow microorganisms in culture, previously a major impediment to pathogen identification. For example, in 2003, sequencing of samples from infected patients with the severe acute respiratory syndrome identified the causative agent as a coronavirus. Comparison of sequences of multiple isolates of an organism from a single epidemic gives a picture of the organism's evolution, allowing one to infer where the outbreak began and how the infection spread. Sequencing has been used to determine the origins of historical outbreaks of cholera, tuberculosis, and the 2009 H1N1 influenza. The clinical application of NGS to infectious disease was highlighted recently when the source of carbapenem-resistant *Klebsiella pneumoniae* in a hospital outbreak was identified by sequencing isolates of the bacteria—in real time—from infected individuals and examining the genetic differences.[18]

TABLE 43-2 MOLECULAR MARKER INFORMED CANCER THERAPIES (TARGETED THERAPEUTICS)

BIOMARKER	DRUG	CANCER TYPE	FDA DRUG LABELING RECOMMENDED OR REQUIRED
Estrogen receptor	Tamoxifen	Breast	Yes
Her2/neu	Trastuzumab	Breast	Yes
EGFR	Cetuximab	Colorectal	Yes
Kras	Cetuximab	Colorectal	Yes
EGFR	Panitumumab	Colorectal	Yes
Kras	Panitumumab	Colorectal	Yes
DPYD	5-FU	Breast/colorectal	No
EGFR	Erlotinib	Lung	No
EGFR	Gefitinib	Lung	No
BCR-ABL	Imatinib	CML	Yes
C-KIT	Imatinib	CML/ALL	Yes
ALK	Crozotinib	Lung	Yes
BRAF	Vemurafenib	Melanoma	Yes

5-FU = 5-flurouracil; ALL = acute lymphoblastic leukemia; CML = chronic myelogenous leukemia; FDA, U.S. Food and Drug Administration.

E-TABLE 43-1 SELECTED MOLECULARLY GUIDED THERAPEUTICS AND INDICATIONS

THERAPEUTIC	MOLECULAR TEST	INDICATION
Cancer treatment regimens	Oncotype DX 21-gene assay	**Breast cancer**: 21-gene expression score linked to the likelihood of breast cancer recurrence in women and the magnitude of benefit from certain types of chemotherapy and hormonal therapy
Irinotecan	*UGT1A1*	**Colon cancer**: variations in the *UGT1A1* gene can influence a patient's ability to break down irinotecan, which can lead to increased blood levels of the drug and a higher risk for side effects.
Carbamazepine	*HLA-B*1502*	**Epilepsy and bipolar disorder**: serious dermatologic reactions and *HLA-B*1502* allele. Before initiating therapy, testing for *HLA-B*1502* should be performed in patients with ancestry in populations in which *HLA-B*1502* may be present.
Abacavir	*HLA-B*5701*	**HIV**: test determines patients most likely to experience an adverse hypersensitivity reaction.
Omeprazole Pantoprazole Esomeprazole Diazepam Nelfinavir Rabeprazole Voriconazole Clopidogrel *CYP2D6* Atomoxetine Fluoxetine HCl Olanzapine Cevimeline hydrochloride Tolterodine Terbinafine Tramadol Acetaminophen Clozapine Aripiprazole Metoprolol Propranolol Carvedilol Propafenone Thioridazine Protriptyline HCl Venlafaxine Risperidone Tiotropium bromide Tamoxifen Timolol maleate	AmpliChip DMET *CYP2D6/CYP2C19*	**Multiple diseases**: these tests are used as an aid in determining treatment choice and individualizing treatment dose for therapeutics that are metabolized primarily by the specific enzyme about which the system provides genotypic information.
Warfarin	*CYP2C9*	**Venous thrombosis/stroke**: increased bleeding risk for patients carrying either the *CYP2C9*2* or *CYP2C9*3* alleles
Warfarin	*VKORC1* (vitamin K epoxide reductase)	**Venous thrombosis/stroke**: single-nucleotide polymorphisms in the *VKORC1* gene (*-1639G/A* allele) associated with lower dose requirements
Clopidogrel	*CYP2C19*	**Coronary artery disease:** increased risk for stent thrombosis and secondary events following percutaneous interventions in patients with the *CYP2C19*2* variant
Immunosuppressive drugs	AlloMap gene profile	**Heart transplantation**: blood gene expression score to monitor a patient's immune response after cardiac transplantation and to guide immunosuppressive therapy
Pharmaceutical and surgical prevention options and surveillance	*BRCA1, BRAC2*	**Breast cancer**: guides surveillance and preventive treatment based on susceptibility risk for breast and ovarian cancer
Pharmaceutical and lifestyle options for disease prevention	Familion 5-gene profile	**Heart disease**: guides prevention and drug selection for patients with inherited cardiac "channelopathies" such as long QT syndrome that may lead to cardiac rhythm abnormalities
Mercaptopurine Thioguanine Mercaptopurine Azathioprine	*TPMT* (thiopurine *S*-methyltransferase)	**Acute lymphoblastic leukemia**: patients with inherited little or no TPMT activity are at increased risk for severe toxicity from conventional doses.
Maraviroc	CCR5 promoter and coding polymorphisms	**HIV:** determines whether the patient is likely to respond or not

THE EXPRESSED GENOME

Complex Multimarker Genomic Tests for Disease Diagnosis and Prognosis

Beyond DNA sequence, measures of gene expression, proteins, metabolites, and epigenetic changes are being used to generate comprehensive profiles of biologic systems in health and disease. Many of the computational challenges of analyzing these large, complex data sets are being addressed to yield next-generation biomarkers that are multianalyte, diagnostic, prognostic, and predictive. A growing number of marketed tests now typically measure protein or RNA levels, often with complex algorithms, enabling diagnosis and prognosis (see Table 43-1). One example is Oncotype DX (Genomic Health Inc., Redwood City, CA), a test that examines expression of 21 genes in tumor tissue to determine the likelihood of disease recurrence in women with early-stage hormone estrogen receptor–positive breast cancer. The test, which is currently covered by many major insurance companies, analyzes expression levels and converts them to a recurrence risk score that has been shown to help guide treatment in patients, reduce overall health care costs, and improve outcomes.[19] Other examples include MammaPrint (Agendia Inc., Irvine, CA), which analyzes the expression of 70 genes to determine whether patients are at high or low risk for breast cancer recurrence; OVA1 (Vermillion, Inc., Austin, TX), a five-protein test that gauges whether a woman's ovarian mass is malignant and requires surgery; AlloMap (XDx Expression Diagnostics, Inc., Brisbane, CA), an 11 blood gene RNA signature for monitoring rejection after cardiac transplantation; and Corus CAD (CardioDx, Inc., Palo Alto, CA), a 23-gene blood RNA signature to screen for obstructive coronary artery disease.

Despite their complexity, in vitro diagnostic multianalyte index assays (IVDMIAs) like these are finding their way to the clinic. The 2007 draft guidance from the FDA suggested that IVDMIAs are used to make critical health care decisions and thus should be regulated by the FDA. Some of the marketed IVDMIAs have demonstrated analytical and clinical validity, but evidence of clinical utility is usually lagging. Moreover, the very nature of IVDMIAs presents challenges to insurers, who grapple not only with limited data on clinical utility but also with how to reimburse such tests that comprise both a laboratory component and an associated algorithm used to score risk, the latter part being integral to realizing the test's value.

The success of some IVDMIAs is evidence of the power of computational biology but also of the importance of advocacy and financial resources that the commercial developers of these tests must bring. Companies developing IVDMIAs are able to finance key studies aimed at demonstrating clinical validity, navigate regulatory hurdles, advocate for coverage by insurance companies, and disseminate their tests through marketing to health care providers. Their efforts offer valuable lessons on the effective translation of complex molecular tests to medicine.

Proteomics

The large-scale study of proteins, *proteomics*, allow for both protein identification and differential expression between two physiologic states (such as health and a specific disease). Quantitative proteomics, in which global differences in protein abundances are measured, continues to be a priority area for biomarker discovery and molecular medicine. This area has been dominated by stable isotope approaches, but recent label-free quantitative methods have been developed that rely on the measured intensity of a peptide ion and compares this to its intensity in other samples. Label-free methods have the advantage of higher throughput and fewer sample manipulation steps. Multiple—or selected-reaction monitoring of specific peptides within biofluids allows quantitation of absolute abundance of proteins in clinical samples. Although this technology is relatively immature in its applications to human health and disease, compared with RNA and metabolic profiling, it is anticipated that these methods, combined with the development of mass spectroscopy technology, will advance proteomics to more routine use in disease classification and diagnosis, prognosis, and pharmacogenomics within the next several years.

Metabolic Profiling

A metabolic profile is very similar to some of the traditional targeted profiles, such as a lipid profile, although it is more comprehensive. *Metabolomics* measures changes in the metabolic or chemical milieu that are downstream of genomic and proteomic alterations. It is estimated that humans contain approximately 5000 discrete small molecule metabolites, and the identification of metabolic fingerprints for specific diseases may have particular practical utility for the development of therapies because metabolic changes immediately suggest enzymatic drug targets. Similar to genomics and proteomics, metabolomics may be useful in disease diagnosis, prognosis, and drug development. In particular, metabolomics will likely be a valuable tool in assessing drug toxicity. Targeted mass-spectroscopy-based metabolic profiling has also been increasingly applied to studies of human diseases and conditions. These tools are being applied to diverse areas, such as diabetes, obesity, cardiovascular disease, cancer, and mental disorders.

CLINICAL IMPLEMENTATION OF MOLECULAR PROFILES

In order for molecular medicine to be practiced, it must be woven into current systems of health care delivery, with due consideration given not only to the providers of health care but also to the organizations in which they practice as well. Implementation scientists have outlined various aspects that need to be considered in order for molecular medicine to take hold in the clinical setting. Beyond the scientific soundness of the molecular or genomic test, measured by a strong evidentiary base and regard for potential benefits and harms, there is consideration of how the new test will integrate into the clinical workflow. Consideration should be given to aspects such as access to a laboratory certified by the Clinical Laboratory Improvement Amendments of 1988, methods for sample preparation and transport, test ordering, and receipt and delivery of results. Genomic test implementation is complicated by issues of privacy, complex interpretation of results, and the need to involve third parties for counseling in some cases; they may require the development of new systems to accommodate them.

A robust means of integrating genomic and molecular data into electronic health records will be required, with consideration of not only data storage formats and privacy issues but also appropriate decision support tools for prompting their use at the point of care and delivering results in an easily interpretable format. Currently, there are several examples of decision support tools, such as Warfarin Dosing (www.WarfarinDosing.org), but they are typically standalone tools and not part of routine clinical workflow. To maximize their effectiveness, such tools should be integrated into electronic health records. Tapping into the collective knowledge and experience of various institutions working in this space would greatly facilitate this effort. Ultimately, a national, standardized technical architecture for integrating clinical decision support into electronic health records will be required. Notable efforts in this space include those of Health Level 7 (http://www.hl7.org), an organization that provides interoperability standards for the exchange, integration, sharing, and retrieval of electronic health information. Through their Clinical Genomics Workgroup, this organization has developed a standards guide for genetic testing that includes document templates to support integration of genetic testing into electronic health records.[1] Appropriate clinical decision support, provided in the context of the electronic health record, will greatly facilitate the diffusion and uptake of genomic medicine.

REVIEW QUESTIONS

1. Genome sequencing of DNA can be used for all of the following *except* which one?

A. Diagnosis of rare diseases
B. Detection of pharmacogenetic variants
C. Newborn screening
D. Prognosis of cancer
E. Diagnosis of infection

Answer: D Various types of genome sequencing have served special clinical functions. Exome sequencing is being increasingly used to diagnose rare genetic diseases and patients with diagnostic dilemmas. Germline genotyping has allowed prediction of adverse events and dosing of many commonly used drugs; although these discoveries have been "actionable," most have failed to diffuse widely into clinical practice at this time. Screening newborns, prenatal diagnosis, and preconception carrier testing are feasible for identified mendelian disorders. In infectious diseases, diagnosis of causative pathogens can be performed by next-generation sequencing, which may in the future supplant the need to first grow microorganisms in culture. Genome sequencing has not been demonstrated to be useful for prognosis of cancer at this time.

2. Transcriptional (RNA) profiling may be useful for all of the following *except* which one?

A. Susceptibility
B. Diagnosis
C. Prognosis
D. Pharmacogenetics
E. Monitoring

Answer: A Next-generation sequencing has allowed sequencing of RNA transcripts in cells. The so-called transcriptome, unlike the static genome, is continually changing. It allows examination, at any given time, of alternatively gene-spliced transcripts, post-transcriptional changes, gene fusion, and changes in gene expression. Transcriptional (RNA) profiling has been applied to diagnosis, prognosis, pharmacogenomics, and monitoring, but not susceptibility analysis.

3. Among the great challenges to implementing genomic diagnostics in the clinic is which one of the following?

A. The precision of the results
B. The evidence to support use
C. The ability of the laboratories to perform the test
D. Their integration into electronic medical records
E. Lack of patient understanding

Answer: B Surmountable challenges to implementing genomic diagnostics at the bedside include increasing the precision of results, expanding the availability of expert laboratories to perform the tests, the ability to integrate the information into electronic medical records, and lack of understanding by patients who are, however, now becoming increasingly savvy about this aspect of their own health care. Evidence to support the utility and cost-effectiveness of wide application of genomic diagnostics in clinical practice is only now being taken up by investigators in comparative effectiveness and health services research.

4. Which of the following describes the microbiome?

A. A small genome
B. A community of microbes colonizing humans
C. A tool used to make thinly sliced materials (e.g., paraffin blocks)
D. The sequence of a virus or bacterium
E. An organelle of the cell

Answer: B The microbiome is the community of microbes that colonize a human host. It is the ecological community of commensal, symbiotic, and pathogenic microorganisms that actually inhabit our body space and outnumber our own native human cells by a ratio of 10 : 1.

5. Which of the following methods may be used for detection of microbial pathogens?

A. Transcriptional profiling
B. Metabolomics
C. Sequencing
D. DNA methylation
E. Proteomics

Answer: C At this time, sequencing is used to detect and identify a microbial pathogen.

REGENERATIVE MEDICINE, CELL, AND GENE THERAPIES

LIOR GEPSTEIN AND KARL SKORECKI

CELL THERAPY

Introduction and Definitions

A remarkable clinical need exists for the development and clinical assessment of various methods to facilitate the regeneration of injured or diseased tissues and organs. This need derives from the unrelenting prevalence of trauma, congenital disorders, ischemia, and degenerative processes, which becomes increasingly urgent as the global population expands and ages. Cancer is tied to this field both directly (e.g., replacement of lost vital organ function as a result of cancer invasion or treatment modalities, cell-based delivery of cancer immune and gene therapies) and indirectly (e.g., role of stem cells in cancer

pathogenesis, risk for tumorigenesis in stem cell–based therapies). The recent developments in stem cell biology, molecular interventions, biopolymers, and other related biologic and engineering disciplines have paved the way to the emerging research and clinical discipline of regenerative medicine.[1]

Regenerative Medicine

Regenerative medicine seeks to harness methods for the replacement or repair of dysfunctional cells, tissue, or organs in an attempt to restore normal function. It therefore draws on therapies from the three conventional pillars of medical therapeutics (pharmaceuticals, biologics, and medical devices) as well as from the newest platform technology, namely, cell therapy. The long-term goal of regenerative medicine is to cure disease by replacing the lost functions of tissues and organs, and thus it truly represents a paradigm shift from conventional therapies aiming to alter the natural course of disease or to provide symptomatic control. Consequently, regenerative medicine aims to develop curative strategies for unmet clinical needs such as diabetes, heart failure, and neurodegenerative disorders, among others.

Cell Therapy

Cell therapy involves the application of cells to achieve a therapeutic benefit, regardless of the cell type or clinical indication. Although achieving tissue and organ regeneration through cell replacement represents an important goal of cell therapy technology, its applications may reach far beyond the field of regenerative medicine. Hence, the spectrum of cell therapy approaches may range from permanent cell replacement strategies (attempting to replace lost or dysfunctional cells) to more transient cell therapies aiming to modulate disease progression or to protect tissues at risk, to achieve immunomodulatory effects (e.g., for prevention of graft-versus-host disease), to act as vehicles for the delivery of genes or gene products (cell-based gene therapy strategies), and even to act as cell-based cancer vaccines. This chapter focuses on the use of cell therapy for regenerative medicine and specifically concentrates on the potential role of different stem cell types to meet this challenge.

Stem Cells

Stem cells possess two defining properties: (1) the capacity for self-renewal and (2) the ability to differentiate into cell types with specialized cellular functions (Fig. 44-1). This may occur at the individual stem cell level through the process of asymmetrical cell division or at the cell population level wherein a subset of cells differentiate and the remaining stem cells remain dormant or replicate themselves as stem cells. After asymmetrical cell division, non–stem cell derivatives may either generate a pool of organ system–restricted, transit-amplifying cells with enhanced proliferative capacity or continue to differentiate by epigenetic and gene expression profile changes until reaching the terminally differentiated state. This conceptual framework was developed after the discovery of bone marrow cells that were capable of reconstituting the adult hematopoietic system. These hematopoietic stem cells constitute the basis for hematopoietic stem cell transplantation, the only form of stem cell therapy currently routinely well established in clinical practice (Chapter 178).

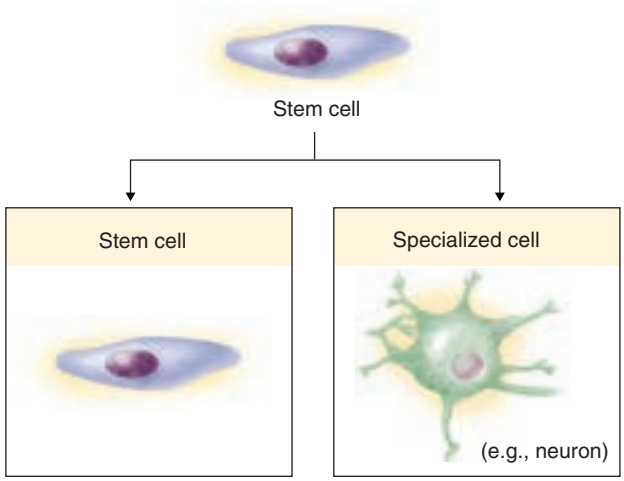

FIGURE 44-1. Asymmetrical cell division. Although this first characteristic was considered a required characteristic for stem cells based on their original description in the adult hematopoietic system, not all cell types currently named as stem cells necessarily display this property. For instance, human embryonic stem cells divide by symmetrical cell division.

The different stem cells types are routinely classified based on the protein or transcription factors they express, but also according to three basic additional attributes. These include replicative capacity (limited vs. unlimited), the scope or potency of differentiation (e.g., pluripotent, multipotent, oligopotent, unipotent), and their place in the life history of the organism (developmental or postdevelopmental). Thus, more recent terminology has broadened use of the term *stem cells* to cover a wider array of cell types that contribute to organ development or have the capacity to repopulate tissues and organ systems. The term *stem cells*, together with the formulations noted previously, has also recently been extrapolated to describe certain cellular subpopulations that may be principally responsible for the growth of malignant tumors. However, because cancer stem cells have no role in tissue regeneration, they are considered in Chapter 181.

Adult (Postnatal) Stem Cells

After birth, many tissues are thought to contain a subpopulation of cells with the capacity for extended self-renewal, combined with the ability to differentiate into more mature cell types with specialized functions (Fig. 44-2). Adult stem cells, thought to represent less than 0.01% of the total number of cells, are located in specialized supportive niche compartments at various sites within the hematopoietic system and elsewhere, and respond to cues in their local microenvironment. As a result of the success of hematopoietic stem cell transplantation in the treatment of bone marrow failure or in conjunction with myeloablative therapy in malignancy, scientists have been motivated to find adult stem cells in other organs. Adult tissues and organ systems reported to contain putative stem cells include bone marrow (hematopoietic and mesenchymal compartments) and peripheral blood, blood vessel endothelium, dental pulp, epithelia of the skin, adipose tissue, digestive system, cornea, retina, testis, and liver. Similar stem/progenitor cells were also reported in organs historically not thought to contain such cells, such as the central nervous system, the heart, and the kidney. Whether adult stem cells represent remnants of developmental stem cells that persist into adulthood for purposes of organ maintenance and repair or represent a distinct cell type dedicated for this latter purpose is not clear. Importantly, in many organs, despite the presence of such tissue-specific stem cells, their regenerative capacity is still inadequate to deal with massive cell loss such as occurs, for example, after a large myocardial infarction or after ischemic brain injury.

Embryonic and Induced Pluripotent Stem Cells

In contrast to adult stem cells that have relatively limited differentiation potency, cells in the developing preimplantation embryo still retain the capacity to differentiate into derivatives of all three germ layers (ectoderm, mesoderm, and endoderm), eventually contributing to all tissues in the body (Fig. 44-3). In normal development, however, such cells do not persist beyond the blastocyst stage. When isolated from unused preimplantation blastocysts generated for in vitro fertilization, the inner cell mass cells isolated can be used to generate human embryonic stem cell (hESC) lines (see Fig. 44-3). The generated hESCs exhibit unlimited self-renewal in cell culture in the undifferentiated state, while retaining the capacity to differentiate into cell derivatives of all three germ layers, essentially giving rise to any cell type in the body. Taking advantage of lessons learned from embryology, scientists were able to utilize the sequential application of different combinations of growth factors to achieve efficient differentiation systems from hESCs, yielding purified populations of different types of neurons, glial cells, cardiomyocytes, vascular endothelial and smooth muscle cells, pancreatic β cells, hepatocytes, different blood cells (platelets, red blood cells), and several other cell lineages.

One of the limitations of the hESC technology is the inability to derive such cells from an adult individual, preventing their utilization in a patient-specific manner. These limitations can be overcome with the introduction of induced pluripotent stem cell (iPSC) technology.[2] This approach allows adult somatic cells (e.g., fibroblasts) to be reprogrammed into pluripotent stem cells by introduction of a set of transcription factors linked to pluripotency (the originally reported combination of factors included OCT3/4, SOX2, c-MYC, and KLF4). The human iPSCs (hiPSCs) generated in this manner can then be coaxed to differentiate into a variety of cell types, using differentiation protocols similar to those already in place for hESC (Fig. 44-4). Importantly, because the hiPSCs can be generated in a patient-specific manner, this technology can potentially be used to develop autologous cell-replacement strategies that can evade the immune system, to generate patient- and disease-specific models of different genetic disorders, and to establish screens for drug testing and drug discovery.

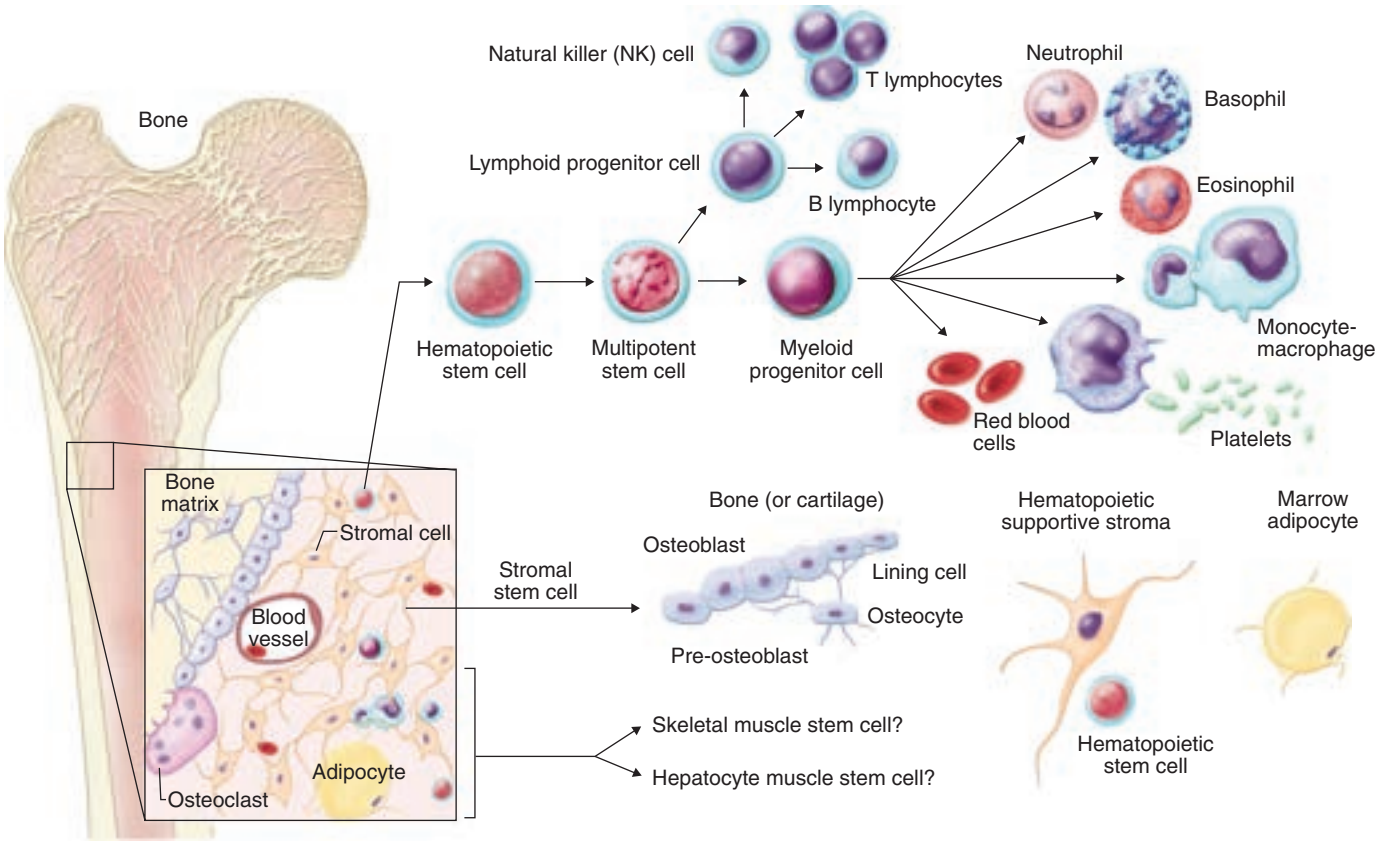

FIGURE 44-2. Adult stem cells. Adult stem cells can be multipotent and have the capacity to differentiate into a limited number of different cell types, often restricted to a given tissue or organ system, as in the case of adult hematopoietic or epidermal stem cells. Two stem cell types have been isolated from adult bone marrow—the hematopoietic stem cell and the mesenchymal stem cell. Adult mesenchymal stem cells of bone marrow origin, although their range of differentiation has been shown to be broader than that of any other adult stem cell type, do not reach pluripotency. It is thought that in some organ systems, such as the gastrointestinal epithelium, a unipotent pool of progenitors exists for repopulating a rapid population turnover of only one type of cell—although it is difficult to be certain whether such progenitors can be distinguished from the overall population of fully differentiated cells in tissues with high cellular turnover.

Cell Therapy Approaches to Regenerative Medicine

Historically, the field of cell therapy can be traced to the transfusion of blood and blood products (Chapter 177), solid organ transplantation (Chapter 49), in vitro fertilization, and bone marrow transplantation (Chapter 178). Nevertheless, beyond the aforementioned therapies, which have become the mainstay treatments in several medical fields, additional cell therapy approaches are considered highly experimental and are still at different stages of preclinical and clinical development. These ongoing efforts can be conceptually grouped into six different approaches (Fig. 44-5).

Delivery of Bone Marrow– and Blood-Derived Stem/Progenitor Cells

A flurry of studies during the past decade evaluated the ability of bone marrow–derived hematopoietic or mesenchymal stem cells to achieve tissue repair after delivery to a variety of organs. These studies were based initially on the assumption that these types of adult stem cells may display some degree of plasticity, allowing them to transdifferentiate into the relevant cell types (e.g., heart cells, nerve cells, and liver cells) after transplantation into the appropriate tissue environment. Although mounting evidence suggests that such transdifferentiation probably does not occur to a significant extent, many of these studies appeared to result in some degree of functional improvement after stem cell delivery to different organs. This clinical benefit may stem from the secretion of different growth factors by the engrafted cells ("paracrine hypothesis"); these factors in turn are thought to augment endogenous tissue repair mechanisms, improve tissue vascularization, modulate inflammation, and protect tissues at risk.

Delivery or Activation of Tissue-Specific Stem/Progenitor Cells or Induction of Cell Proliferation

In contrast to the conventional dogma, recent evidence suggests that a number of organs previously believed to lack any regenerative capacity (e.g., the brain, pancreas, kidney, and heart) in fact do possess such ability, albeit at a limited capacity. Whether this capability is due to the presence of tissue-specific stem/progenitor cells or due to some replication capability of terminally differentiated cells is still a matter of debate for each organ.

Significant efforts have been made in recent years to isolate such putative tissue-specific stem/progenitor cells based on the expression of general or specific stem cell markers or based on their unique culturing properties. These studies also highlighted the potential of such cells to be cultured in a clonal manner and to give rise to one or more cell types relevant to the organs from which they were isolated. Current efforts to utilize the aforementioned findings for regenerative medicine are focused either on the isolation, ex vivo expansion, and transplantation of such putative stem/progenitor cells back to their respective native organs or on the augmentation of their endogenous reparative potential in vivo. The former strategy can be exemplified in the central nervous system where progenitor cells are harvested, cultivated in culture (as neurospheres), and give rise to different types of neurons and supporting glial cells. Similar efforts have followed in other organs. In the heart, for example, such efforts have already reached early clinical trials, in which autologous cardiac stem cells were harvested from the heart, expanded ex vivo, and then engrafted back to the heart. The latter approach, in contrast, aims to influence putative stem cell niches within damaged organs to enhance the endogenous reparative properties of those stem/progenitor cells. Such an effect may underlie the potential therapeutic benefit of bone marrow–derived stem cells after their delivery to different organs.

The final strategy aims to boost endogenous organ repair through the replication of terminally differentiated tissue-specific cells. Such strategies can either augment the inherent physiologic capability of a given organ (e.g., insulin secretagogues for pancreatic β cells) or attempt to induce replication in cells that have already withdrawn from the cell cycle. Caution is warranted with respect to the latter approach because induction of uncontrolled proliferation (e.g., by genetic manipulation) may increase the risk for tumorigenesis.

Engraftment of Fetal Tissue

The most straightforward approach to organ repair would be to replace the missing cells with identical counterparts. Harvesting and expanding adult

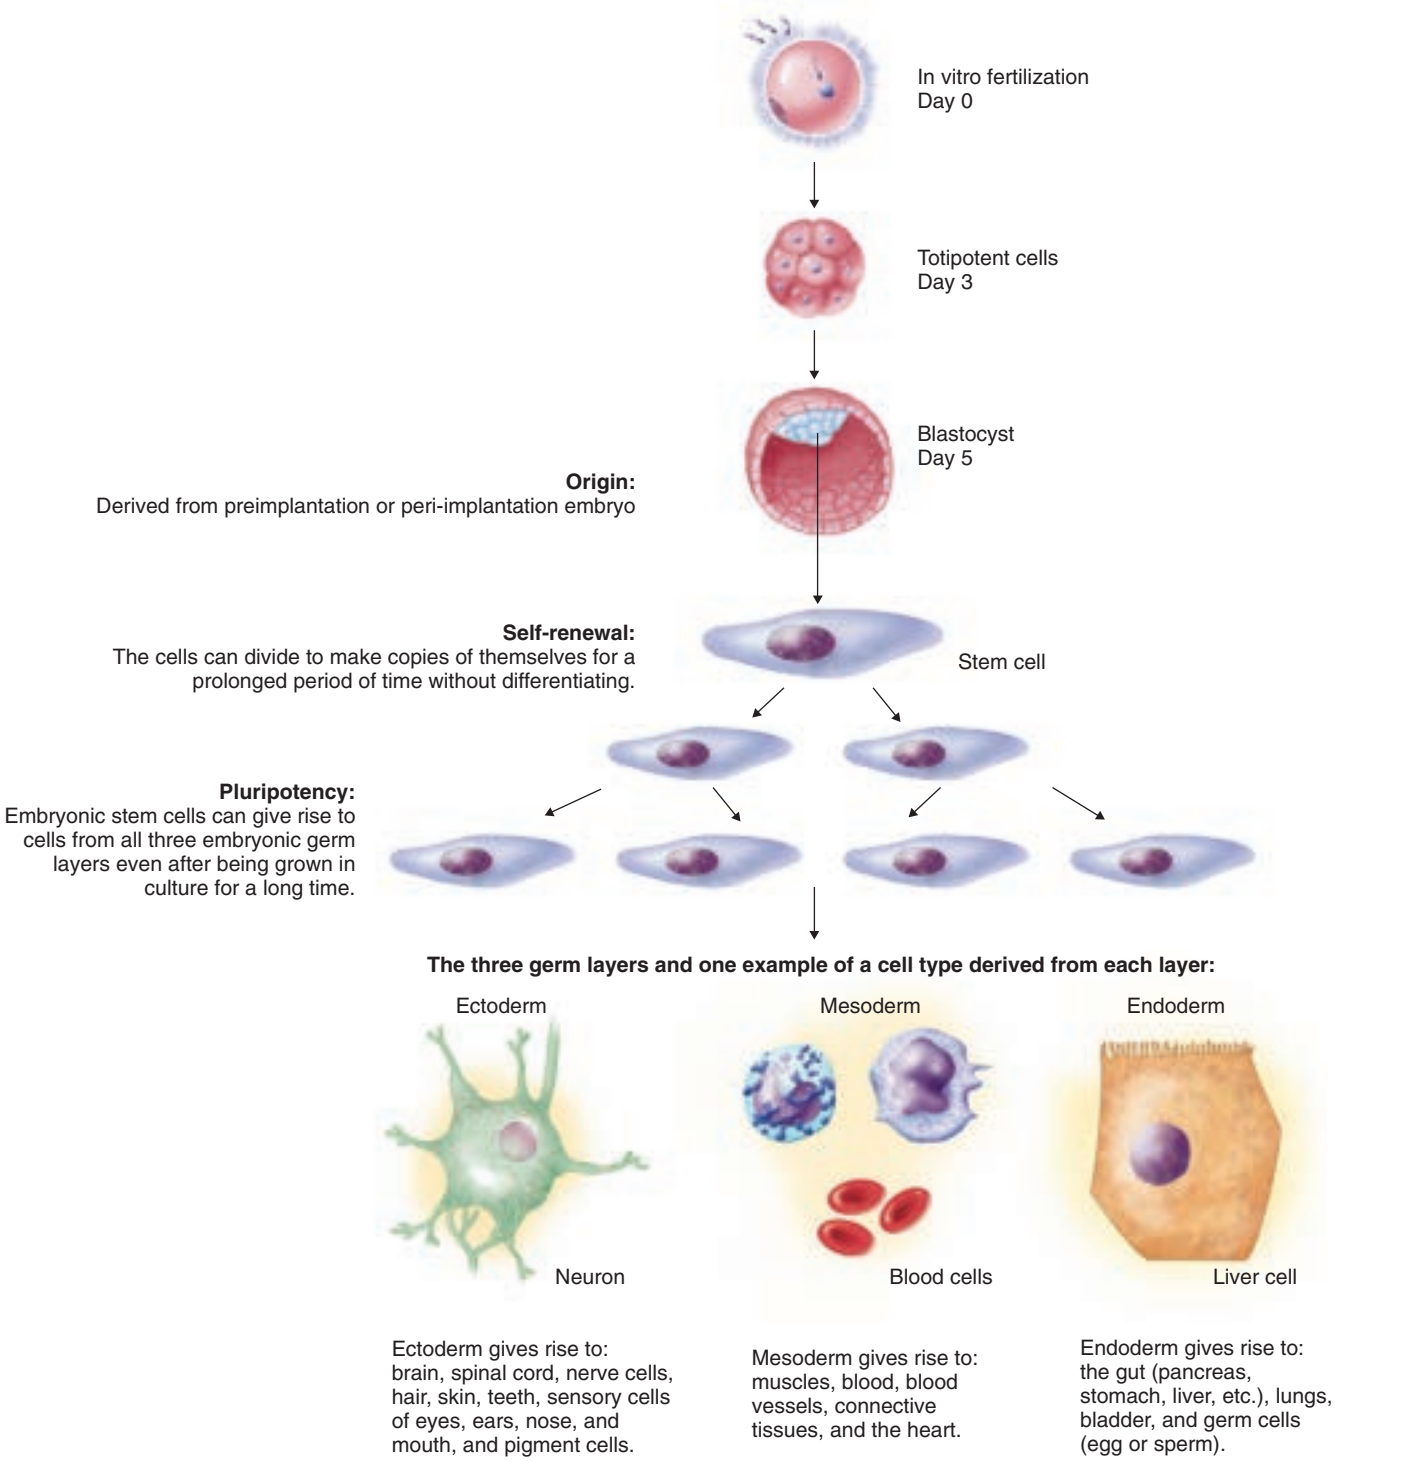

FIGURE 44-3. Embryonic stem cells. ***Totipotency*** **refers to the capacity to differentiate into all cell types in an organism, including extraembryonic tissues, placenta, and umbilical cord, a property confined to the fertilized egg itself, including the cells derived from the first few cell divisions after fertilization.** ***Pluripotency*** **refers to the capacity to differentiate into all the specialized cell types derived from the three germ layers (ectoderm, mesoderm, endoderm) of the developing embryo and is a hallmark feature of embryonic stem and germ cells.**

human cells for transplantation, however, may not be possible in the case of several organs with limited regenerative capacity. During prenatal human development, cells of fetal origin often show enhanced proliferative capacity as well as the ability to differentiate into more than one type of mature or specialized cell. Moreover, animal studies have demonstrated that transplantation of tissues harvested from developing organs (harvested within a specific time window during embryonic development) may give rise to entire functioning organs such as kidneys, lungs, and pancreas. Nevertheless, to date, the only fetal-derived cells that have been used in human clinical applications are the dopaminergic cells derived from the developing fetal nervous system for the treatment of Parkinson disease (Chapter 409). The broader use of fetal tissues for regenerative medicine may be hampered by the limited access to such cells for both technical and ethical reasons, the allogeneic nature of such procedures (requiring immune suppression), and the potential for tumor formation as already described in some case reports.

Transplantation of Ex Vivo Differentiation of Pluripotent Stem Cells

Unlike fetal tissues, hESCs are truly pluripotent (can give rise to advanced cell derivatives of all three germ layers). Importantly, hESCs can be propagated in the undifferentiated state and then coaxed to differentiate into a variety of cell types, giving rise to a potentially unlimited number of specialized cell types for transplantation. Consequentially, numerous preclinical studies have demonstrated the ability of hESC derivatives to engraft, survive,

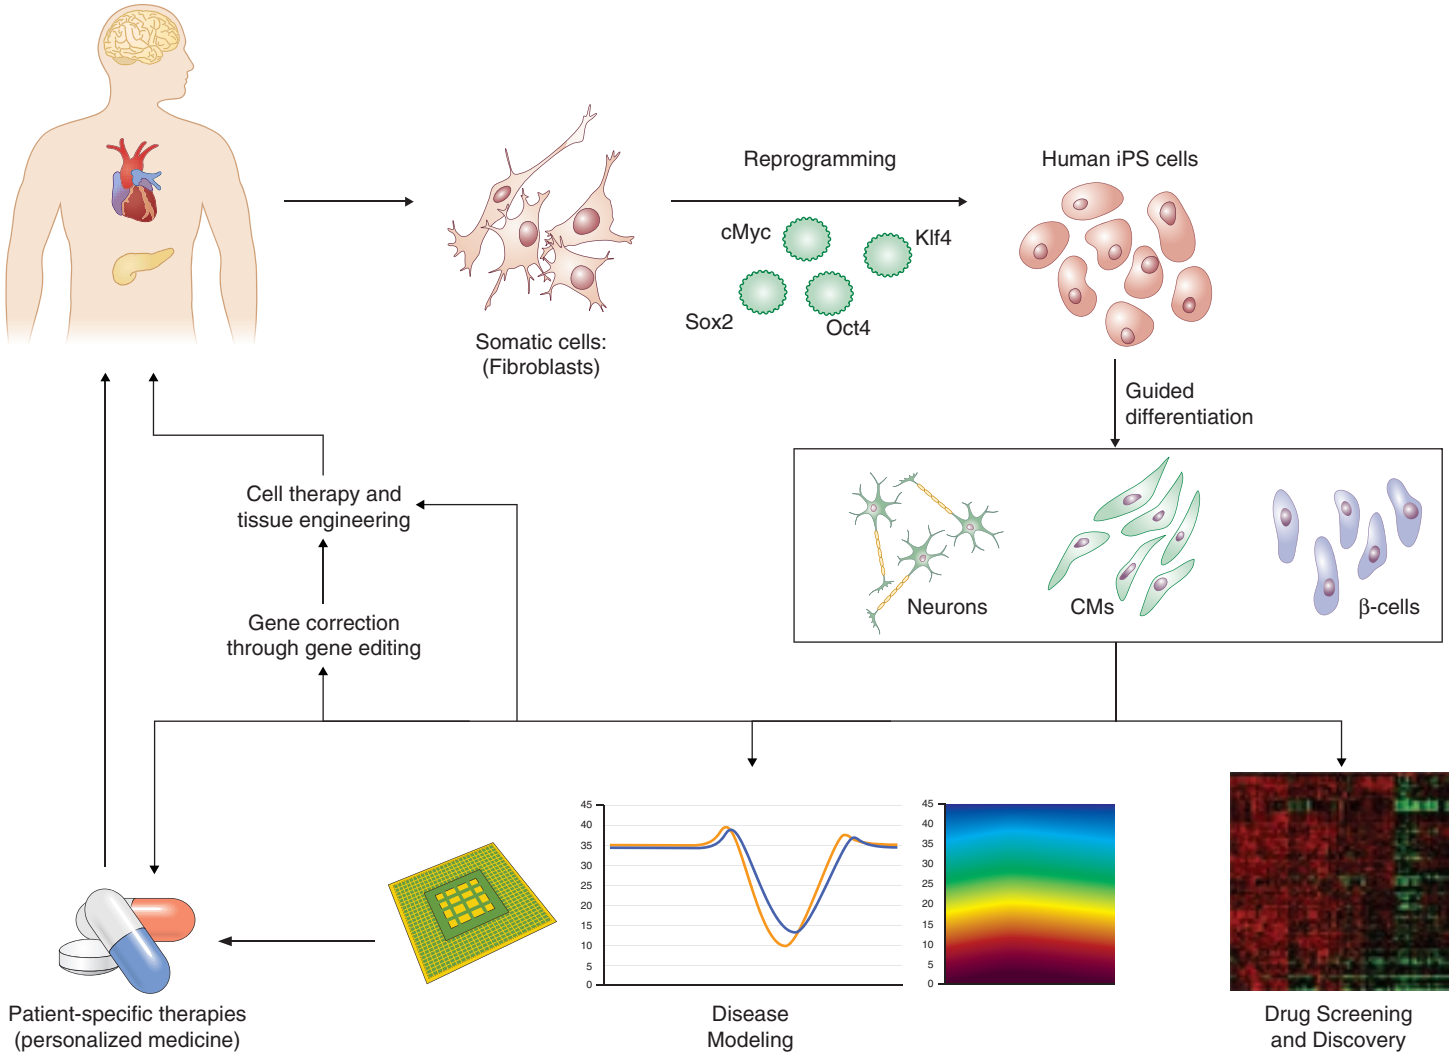

FIGURE 44-4. Application of the induced pluripotent stem cells (iPSC) technology. Patient-specific human iPSC can be generated by reprogramming of adult somatic cells (fibroblasts) with a set of transcription factors and then coaxed to differentiate into a variety of cell lineages. The patient-specific human iPSCs can then be transplanted back to the patient in an autologous manner for regenerative medicine applications. In a similar manner disease- and patient-specific human iPSC models of inherited disorders could be generated ("disease-in-a-dish models") and used for better understanding of genetic disorders, for drug development, and for optimizing patient-specific therapies. Gene editing techniques can be used for mutation correction and for transplantation of healthy cells. CM = cardiomyocytes; iPS = induced pluripotent stem cells.

and improve organ performance in a wide spectrum of relevant animal disease models (e.g., heart failure, Parkinson disease and other neurodegenerative disorders, diabetes). Early clinical studies using hESC derivatives are just emerging and have been focused so far on the retina (transplantation of retinal pigment epithelium [RPE] cells) and spinal cord injury (using oligodendrocyte progenitors).

Despite the significant achievements made with hESCs, the inability to create patient-specific hESCs from adult individuals, the ethical issues arising from destructive use of human embryos, and the anticipated immune rejection associated with such allogeneic cell transplantation impose important hurdles for their clinical utilization. The hiPSC technology provides a potential solution to these challenges. As noted, the patient's own somatic cells (fibroblasts, hair follicles, urine epithelial cells, or blood cells) could be reprogrammed by a set of transcription and chemical factors to yield pluripotent stem cells. The patient-specific hiPSCs could then be coaxed to differentiate to a variety of cell lineages, using protocols similar to those already in place for hESCs. In turn, these differentiated derivatives could then be transplanted either in an autologous or allogeneic manner. Clinical trials using hiPSC-derived cell lineages are expected to be initiated in the coming few years, with the initial targets being macular degeneration (RPE cells), Parkinson disease (dopaminergic neurons), blood product transfusion (hiPSC-derived platelets and red blood cells), and heart failure (cardiomyocytes).

One of the concerns in translating hESCs and hiPSCs into a therapeutic platform is the oncogenic risk. This concern stems from the potential for remaining undifferentiated cells within the cell grafts to form teratomas, from the use of oncogenic reprogramming factors, from the random integration of the viral vectors used in cellular reprogramming ("insertional oncogenesis"), and from genetic instability, potentially leading to both chromosomal aberrations and mutations. Progress to clinical trials requires definitive clarification of this key concern.

Direct Reprogramming

In contrast to the iPSC approach, which seeks to initially reprogram somatic cells to a pluripotent state followed by differentiation of the generated iPSCs to specific cell lineages, recently described direct reprogramming strategies aim to convert the phenotype of one mature cell type (fibroblasts) directly to another. The prototype for such a strategy was the demonstration that *MyoD*, a master regulator of skeletal muscle formation, can convert fibroblasts directly to skeletal muscle. Progress to derive other cell types after this report was delayed for many years because, unlike skeletal muscle, a single master developmental regulatory gene does not exist for most cell lineages.

Based on the experimental approach used to identify the combination of transcription factors that can reprogram somatic cells into iPSCs, researchers evaluated the ability to achieve analogous transcription factor reprogramming strategies to convert the cell fate of somatic cells directly. Consequentially, using a combination of lineage-specific developmental transcription factors, scientists were able to convert terminally differentiated fibroblasts or other somatic cells directly to neurons, β cells, different hematopoietic cell lineages, and cardiomyocyte-like cells. Recent studies have taken this concept a further step forward by demonstrating that transcription factor–based

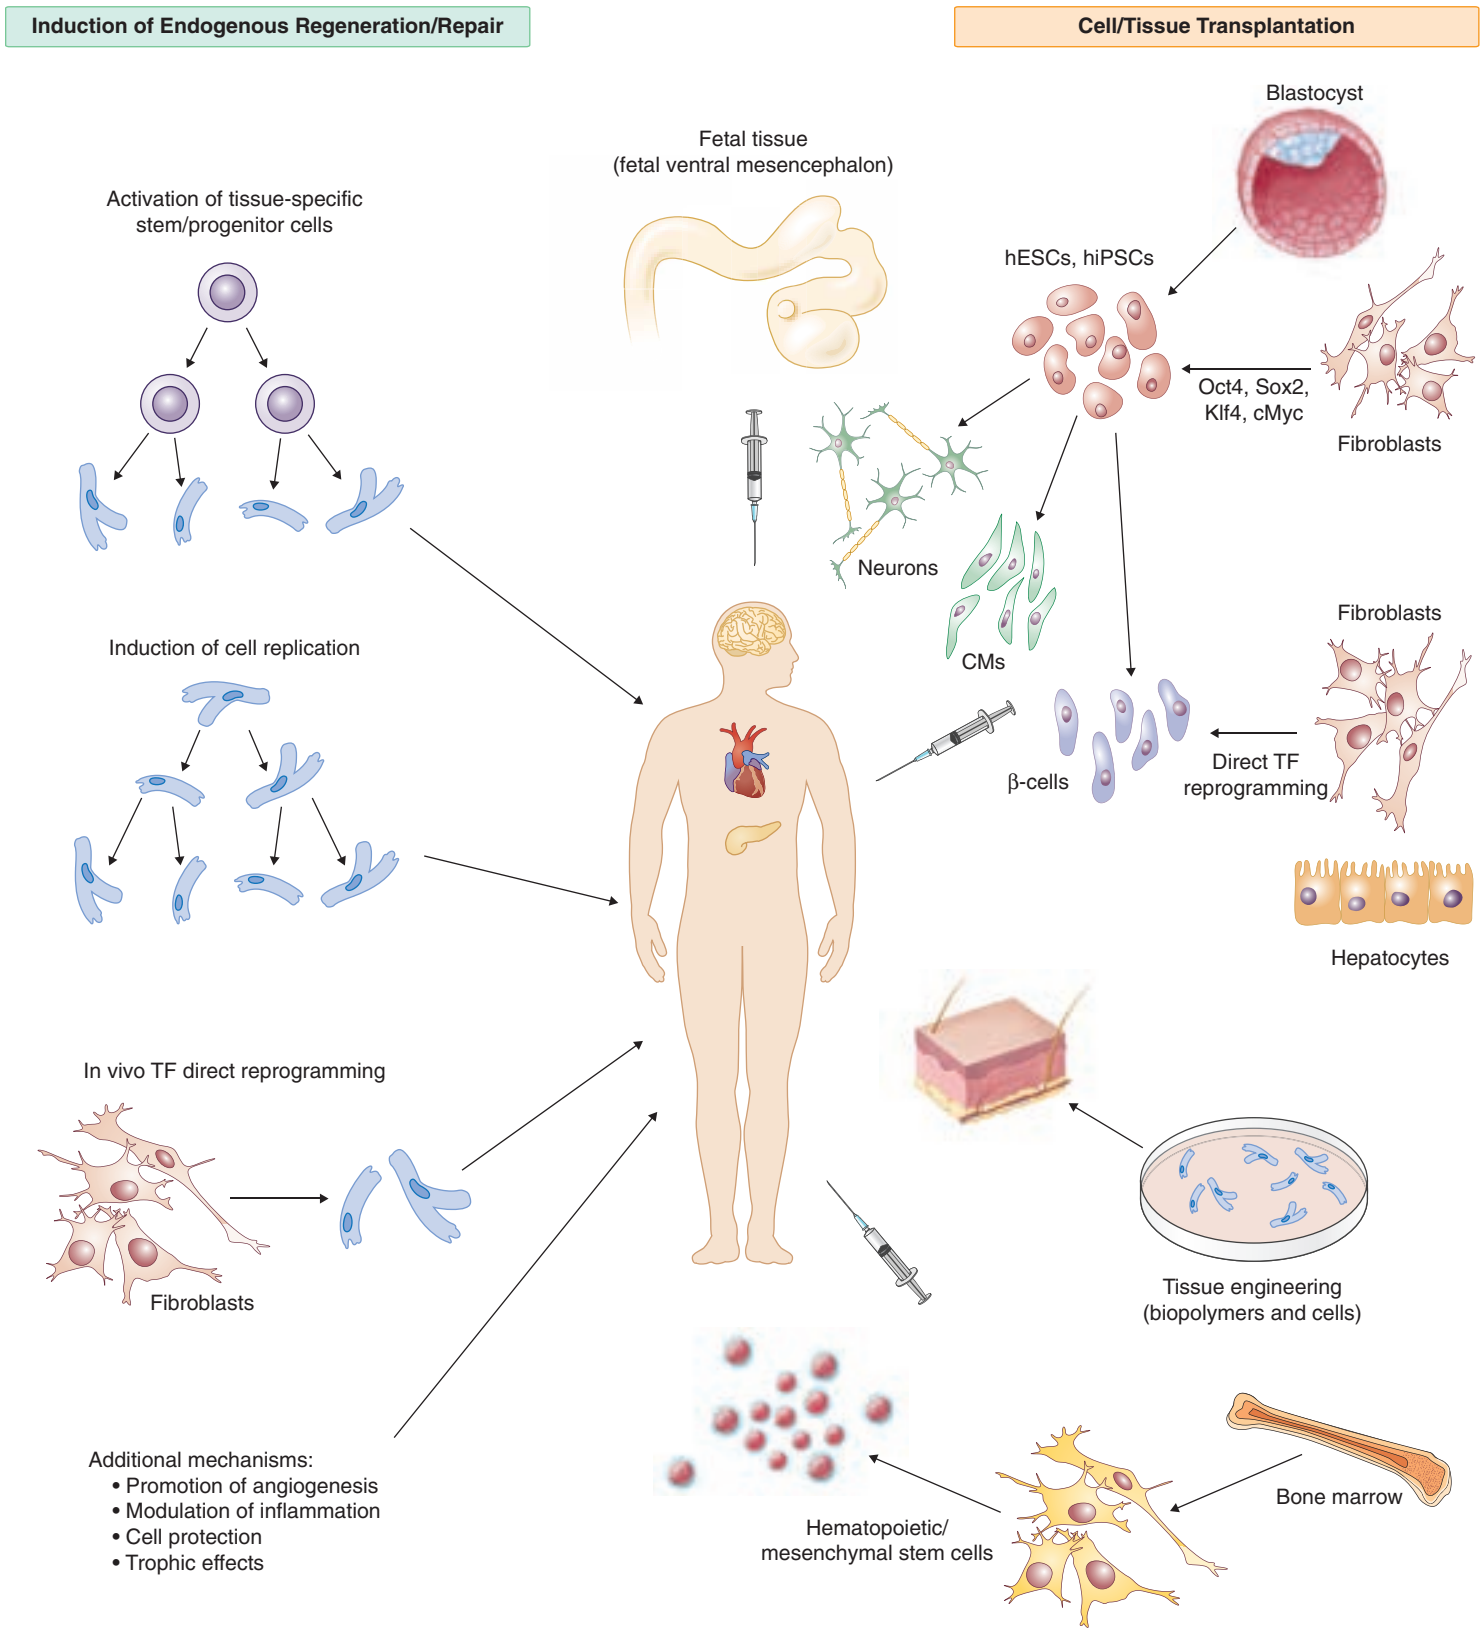

FIGURE 44-5. Conceptual framework for regenerative medicine approaches. These strategies can be divided into those attempting to augment endogenous regeneration *(left side)* and those focusing on transplantation of cells *(right side)*. The former could be achieved through the activation of putative tissue-specific stem/progenitor cells, through induction of cell replication, by in vivo transcription factor (TF)-based direct reprogramming (directly converting one somatic cell [fibroblast] into another), and by several other indirect means (e.g., modulation of inflammation, induction of angiogenesis, trophic effect, protection of tissue at risk). Cell sources that can be used for cell transplantation include fetal tissues (e.g., dopaminergic-rich fetal ventral mesencephalon for Parkinson disease), pluripotent stem cells (human embryonic stem cells [hESCs] and human induced pluripotent stem cells [hIPSCs]), derived cell-lineages, and somatic cells that can be generated ex vivo by direct transcription factor–based reprogramming of fibroblasts. CMs = cardiomyocytes.

transdifferentiation can also be achieved in vivo, suggesting a method whereby resident cells (fibroblasts, hepatic cells, or other cells) could be converted to the appropriate cell types for organ repair. Development of the latter approach for clinical application may be considered more analogous to gene therapy, with the associated advantages, shortcomings, and challenges of this discipline (see later).

Tissue Engineering

Tissue engineering is an interdisciplinary technology combining principles from life sciences and engineering with the goal of developing functional substitutes for damaged tissues and organs.[3,4] Rather than simply introducing cells into a diseased area, in tissue engineering, cells are embedded or seeded onto three-dimensional scaffolds (derived from different biomaterials) before

transplantation. Regardless of the specific clinical application, tissue-engineering strategies usually involve the utilization of combinations of biomaterials, cells, and biologically active factors. The scaffold serves many purposes, including the control of the shape and size of the engrafted tissue, the delivery of biologic signals and adequate biomechanical support to the cells, the induction of vascularization of the graft, and the protection of the cells from physical damage. Scaffolds used in tissue engineering approaches are commonly divided into two general categories: (1) cellular scaffolds that are seeded ex vivo with cells before their in vivo transplantation; and (2) acellular scaffolds that depend on cells in the recipient to repopulate the scaffold with subsequent reconstitution after transplantation. Such tissue-engineered efforts have already reached proof-of-concept clinical trials. These efforts have mainly concentrated on the musculoskeletal system (bone and cartilage repair) but have also targeted other organs such as the heart and even complex organ structures such as the esophagus, trachea, and urinary bladder.

Specific Disease Applications in Cell Therapy

Although a growing number of experimental cell therapies have reached various stages of clinical trials, as yet none has become an established or approved treatment, with the aforementioned exception of hematopoietic stem cells and solid organ transplantation. Nonetheless, with the expectation of significant advances on the horizon, examples of some of the current cell therapy efforts being made in the fields of neurodegenerative disorders, heart failure, and diabetes are provided.

Neurodegenerative Disorders

The central nervous system has limited capacity for regenerating lost tissue both in slowly progressive degenerative neurologic conditions such as Parkinson disease, Alzheimer disease, and amyotrophic lateral sclerosis (ALS) and in acute injuries leading to rapid cell loss (ischemic stroke or traumatic spinal cord injury). Stem cell–based therapies are being explored as potential novel therapeutic paradigms for both acute and chronic neurodegenerative disorders.[5] Consistent with the spectrum of cell therapy–related mechanistic actions described above, these procedures could potentially act through the following mechanisms: (1) cell replacement, whereby cells (precommitted to specific neuronal or glial lineages) are transplanted to replace the specific subtypes of cells that were lost (i.e., dopaminergic neurons in Parkinson disease, motor neurons in ALS, or a mixture of different neuronal and glial subtypes in other disorders); (2) trophic support, whereby the engrafted cells are used to promote the survival of affected neurons or glia or stimulate endogenous repair of the diseased central nervous system through the secretion of neurotrophic factors; and (3) modulation of the inflammatory process thought to contribute to the pathogenesis of many neurodegenerative processes. Achieving the first mechanistic goal, despite being the most attractive, is probably also the most challenging because one would need not only to derive a clinically relevant number of the specific glial or neuronal subtypes or a combination of these cells but also to deliver them to the appropriate site (either focally or diffusely throughout the brain), as well as to assure cell-graft survival, its continuous and appropriate function, and importantly, its integration with the host neuronal network.

Parkinson disease (Chapter 409) involves loss of melanin-containing dopaminergic neurons within the substantia nigra pars compacta of the midbrain, coupled with accompanying depletion of striatal dopamine. This cellular loss is responsible for the major motor features of the disease. In the search for a more definitive therapy than pharmacology, early reports of cell replacement therapy suggested significant improvement in motor function after intrastriatal implantation of mesencephalic dopamine-rich tissue, obtained from aborted human fetuses aged 6 to 9 weeks. Long-term immunosuppressive treatment is essential to allow transplanted dopaminergic neurons to develop into their full functional potential despite the notion of an immunologic sanctuary within the brain. Clinical assessment standards have provided evidence of long-lived graft survival, morphologic and functional integration, and clinical benefit after therapy with cells of fetal origin that have now lasted up to 10 years or longer in some patients. Further progress, however, has been limited by lack of sufficient source tissue to treat a large number of affected patients, prohibitive variability in functional outcome, reports of serious dyskinesias in a subset of treated patients, and ethical considerations.

Given the aforementioned limitations of fetal tissue engraftment, stem cell derivatives could offer a viable alternative for the treatment of Parkinson disease by either replacing the dopaminergic neurons or slowing the degeneration process and restoring the integrity of the nigrostriatal pathway through the release of trophic factors. Importantly, dopaminergic neuroblast-like cells have been generated ex vivo from different stem cell sources, including pluripotent stem cells (hESCs and hiPSCs) by direct fibroblast reprogramming, neural stem cells and progenitors from the embryonic ventral mesencephalon, and adult neural stem cells from the subventricular zone. Preclinical engraftment studies demonstrated that such cells could survive in animal models of Parkinson disease and exert beneficial functional effects after cell maturation. Nevertheless, some properties that are fundamental for successful clinical translation have not been fully met in animal transplantation trials employing human stem cell–derived dopaminergic neurons. Additional challenges that should be addressed include development of methods to prevent the disease process from also destroying the grafted neurons (e.g., engineering the cells to secrete neurotrophic factors) and limiting graft-induced dyskinesia (e.g., by minimizing the number of serotonergic neuroblasts in the grafted tissue).

Investigations of stem cell–based approaches for the treatment of other neurodegenerative diseases, including ALS, Alzheimer disease, Batten disease, stroke, and brain and spinal cord injury, are now moving from experimental animal model studies to planning of clinical trials. Recent reports have shown a major clinical benefit in animal models of directed differentiation and transplantation of hESCs and hiPSCs toward retinal pigment epithelum. Human studies with these cells were recently initiated for patients suffering from macular degeneration.

Heart Disease

Although recent studies have challenged the dogma of the heart being a completely terminally differentiating organ, the endogenous repair mechanisms of the adult heart are usually inadequate in dealing with an extensive myocardial infarction. The resulting decrease in the contractile mass, which is associated with the loss of approximately 1 billion cardiomyocytes, may lead to the development of clinical heart failure (Chapters 58 and 59). With heart failure being the leading cause of hospitalization and with the paucity of donor organs limiting the number of heart transplantations worldwide, it is not surprising that the heart has become the focus of various regenerative medicine efforts.[6]

The first cells that reached clinical trials for heart failure were skeletal myoblasts. Such cells could be harvested (satellite cells) in an autologous manner, expanded ex vivo, and transplanted to the heart. However, skeletal myoblasts display different physiologic properties than cardiomyocytes and cannot form electromechanical connections with host cardiac tissue. Consequentially, these clinical efforts have largely been abandoned because of lack of efficacy as well as evidence suggesting increasing arrhythmogenicity in some patients.

The largest clinical experience in myocardial cell therapy comes from the use of bone marrow–derived stem cells (primarily hematopoietic stem cells and more recently also mesenchymal stem cells). The effects of delivery of such cells (mainly through the coronary circulation) were studied in thousands of patients, primarily in the setting of acute or recent myocardial infarction. These studies revealed either a neutral effect on myocardial performance or mild functional improvement. Although a recent meta-analysis of 33 randomized controlled trials studying transplantation of adult bone marrow–derived cells revealed a statistically significant improvement in left ventricular ejection fraction, this improvement was not associated with a change in mortality.

Bone marrow–derived stem cells are thought to exert their beneficial effects through the secretion of different growth factors rather than transforming to become new heart cells. Consequentially, a cell source that could truly re-muscularize the heart is direly needed. A potential candidate for such a task could be the recently described cardiac progenitor cells. Several reports have described cardiac progenitor cells as multipotent clonogenic cells that could be isolated based on different markers or culturing properties and potentially differentiate into cardiomyocytes and vascular cells. Such cells can be harvested from the heart (during surgery or a percutaneous cardiac catheterization biopsy approach), expanded ex vivo, and then transplanted back to the left ventricle in an autologous manner.

In contrast to the aforementioned cell types, human pluripotent stem cell lines (hESCs and hiPSCs) can undoubtedly become cardiomyocytes during ex vivo differentiation. Research efforts in recent years established efficient directed differentiation systems that could give rise to clinically relevant numbers of cardiomyocytes and demonstrated the ability of the generated cells to engraft, functionally integrate with host cardiac tissue, and improve myocardial performance in animal models of myocardial infarction. Nevertheless, issues related to ethics and the allogeneic nature of the graft (hESCs),

to the inefficient and incomplete reprogramming process (iPSCs), to the heterogeneous and relatively immature properties of the generated cardiomyocytes, to the tumorigenic risk, and to the complex regulatory and financial issues have hindered clinical development of these cells to date.

Most recent efforts in the field have focused on attempting to induce mature cardiomyocytes to reenter the cell cycle (directly or after an initial dedifferentiation phase) or to convert the phenotype of nonmyocytes (fibroblasts) into cardiomyocytes. In the latter approach, recent studies have demonstrated the ability to convert the phenotype of murine fibroblasts both in vitro and in vivo into cardiomyocyte-like cells by the expression of a combination of cardiomyocyte-specific transcription factors (GATA-4, MEF-2C, and TBX-5 in one study). Although these and other efforts have the potential to augment the number of cardiomyocytes and consequentially improve contraction of the failing heart, they are still in the early phase of discovery.

Diabetes Mellitus

Successful pancreatic transplantation and improved glucocorticoid-free protocols for transplantation of islets of Langerhans have been shown not only to restore glucose control in patients with diabetes mellitus but also to prevent or even reverse some of the disease's complications (Chapters 229). However, whole organ or islet-based transplantation approaches are limited both by immunologic rejection and by limitation of an available source of transplantable tissues. This has motivated the search for cell types that can replace (type 1 diabetes mellitus) or augment (type 2 diabetes mellitus) deficient β-cell function.[7]

The development of hESCs and hiPSCs, coupled with improved understanding of β-cell development, has provided a potentially unique cell source to derive β cells for transplantation therapy. β cells make an especially attractive case for cell replacement strategies because only a single cell type is missing, cell replacement does not necessarily need to be performed in the native environment (pancreas), and, theoretically, such cells could even be engrafted subcutaneously. Harnessing lessons from embryology, efficient protocols were developed to promote differentiation of pluripotent cells in vitro into precursor or early-stage β-cell phenotype. More recent efforts have moved the field even closer to clinical application by tackling the challenge of creating more mature and functional β cells.

One of the problems with using β cells for cell replacement therapy is that the autoimmune destruction of endogenous β cells, which underlies the pathogenesis of type 1 diabetes, will probably also result in the destruction of the pluripotent cell–derived β cells, even when derived from an autologous (hiPSCs) source. Consequentially, significant efforts are being made to develop the biotechnologic means (encapsulation technologies) to deliver the cells in an immunoprotective environment that will prevent cell rejection but will retain the capacity of the engrafted β cells to sense glucose and to secrete insulin.

Beyond the derivation of new β cells from pluripotent stem cells, progress has also been made in reprogramming closely related cell types to β cells by the overexpressing of master regulatory transcription factors. Early studies focused on the conversion of hepatocytes to β-like cells through the overexpression of PDX1, the transcription factor MAFA, and NeuroD. In vivo transdifferentiation of mouse acinar cells to β cells has been achieved by transient viral overexpression of three transcription factors (PDX1, NGN3, and MAFA), whereas overexpression of a single transcription factor, PAX4, has successfully converted murine α cells to β cells.

Regenerative strategy focuses on increasing pancreatic β-cell mass by inducing the replication of existing β cells. This therapeutic approach would probably mainly target type 2 diabetic patients by decreasing the burden on existing overworked β cells but may also be beneficial for some patients with type 1 diabetes who still retain some β-cell mass. Whereas several tissues are regenerated by differentiation of tissue-specific stem cells, new pancreatic β cells are derived from the replication of existing β cells. Promising candidates for augmenting β-cell replication were recently identified and include the use of glucokinase activators or betatrophin, a protein secreted by the liver.

Stem Cell–Derived Platforms for Disease Modeling, Personalized Medicine, and Drug Discovery

In addition to the generation of cells for regenerative applications, the ability to grow a wide variety of different specialized cell types of human origin in culture provides unparalleled opportunities for gene and drug discovery and testing. For example, the ability to grow human cardiomyocytes in culture provides a preclinical human cellular-based experimental platform for screening newly developed drugs in terms of their potential to cause QT-interval prolongation and hence the risk for arrhythmia in the clinical setting. Other examples include the creation of an experimental tissue microenvironment of human origin for studying the stromal response to tumor growth and testing anticancer drugs that target tumorigenic responses such as angiogenesis.[8]

The hiPSC technology has further revolutionized this field because it allows for the first time the generation of disease/genotype- and patient-specific hiPSC models of a wide array of inherited disorders. Initial studies focused on diseases with monogenic inheritance, but more recent studies have included diseases with more complex inheritance patterns.[9] Consequently, different types of patient-specific hiPSC-derived neurons, cardiomyocytes, skeletal muscle, blood cells, hepatocytes, and other cell types were demonstrated to recapitulate in a culture dish the abnormal phenotype of a wide array of genetic disorders, including neurodegenerative disorders (e.g., spinal muscular atrophy, familial dysautonomia, ALS, schizophrenia, and even late-onset diseases such as Parkinson and Alzheimer disease), different cardiomyopathies and arrhythmogenic syndromes, a wide array of blood disorders, and several other genetic disorders. These models have already yielded important insights into the mechanisms underlying these disease states and have established unique experimental platforms that will enable the testing of existing therapies in a patient-specific manner (personalized medicine) to evaluate evolving therapies ("clinical studies in the culture dish") and to develop new therapeutic strategies.

GENE THERAPY

Gene therapy can be broadly defined as the transfer of genetic material into cells to restore or correct a cellular dysfunction or to provide a new cellular function in an attempt to cure a disease or at least to improve the clinical status of a patient. The use of genes as therapeutic platforms emerged during the mid-20th century, and in the 1990s, the first regulated registered studies were performed in the United States. In the first clinical study, a 4-year-old girl with adenosine deaminase (ADA) deficiency was treated by transfecting the ADA gene into her white blood cells, resulting in improvements in her immune system. Since then, more than 10,000 patients have been involved in more than 1700 gene therapy clinical studies performed throughout the world. The most common patient populations targeted in these studies have been cancer patients (more than 1000 studies), with another important category being monogenic inherited disorders (more than 100 studies). Although gene therapy initially was conceived as a way to treat life-threatening disorders (inborn errors, cancers) refractory to conventional treatment, it is now being explored for non-life-threatening conditions that adversely affect a patient's quality of life.

Although early clinical failures and a number of reported deaths (only two of which were actually attributed directly to gene therapy) and cases of gene therapy–related leukemic transformation led many to dismiss gene therapy as hazardous and premature, recent clinical successes have bolstered new optimism in the promise of this discipline. These include entirely novel initiatives in treating primary immunodeficiency syndromes, the improvement of vision in patients with the retinal disease (e.g., Leber congenital amaurosis), the successful treatment of X-linked adrenoleukodystrophy,[10] and the encouragement of experimental results in treating different forms of cancer.

Despite these success stories, only a few gene therapy agents are currently approved and available. Fomivirsen (Vitravene) is used for the treatment of cytomegalovirus retinitis in patients with AIDS. In 2012, Glybera became the first gene therapy treatment to be approved for clinical use in either Europe or the United States. Glybera uses a virus injected into a patient to deliver a working copy of a gene for producing lipoprotein lipase (LPL) to treat the rare inherited disorder of LPL deficiency. Finally, the *p53* tumor suppressor coding sequence in an adenovirus vector is used for the treatment of head and neck cancer but is registered only in China.

Classifications and Mechanisms of Action

In general, somatic gene therapy applications can be divided into those aiming to treat or correct various genetic disorders and those targeting non-genetic diseases by attempting to alter cell, tissue, and organ function in a favorable manner. According to the World Health Organization, there are more than 10,000 disorders with monogenic inheritance described in humans (http://www.who.int/genomics/public/geneticdiseases/en/index2.html), but only a small fraction of these may be amenable to gene therapy. Traditional gene therapy efforts for inherited disorders have mainly focused on the

exogenous expression of genes encoding the missing or abnormal proteins and to a lesser extent also on altering the abnormal gene expression patterns. Future efforts are expected to shift the focus from uncontrolled overexpression of the missing protein to directly correcting the mutation at the DNA level (gene-editing strategies) in affected cells, using the newly emerging technologies known as the TALEN and CRISPR[11] approaches described in greater detail later under Gene Editing. With successful widespread use in research studies and proven applications in editing of gene sequence in stem cells, the transition to clinical application is sure to follow.

For nongenetic disorders, gene therapy efforts are aimed at overexpressing a specific protein in an attempt to alter cellular function favorably (e.g., to increase contractility in heart failure by overexpression of the sarcoplasmic reticulum calcium ATPase SERCA2a), protect tissue at risk (e.g., in acute kidney injury), exert paracrine effects through local secretion of specific proteins by the engineered cells (e.g., promote angiogenesis in ischemic tissues or induce neurotrophic effects in neurodegenerative disorders), and even secrete proteins systemically (e.g., in gene therapy trials attempting to correct bleeding disorders by secretion of coagulation factors or for systemic delivery of hormones such as erythropoietin for the treatment of anemia). Major efforts in the gene therapy arena to date have been in designing various methods to treat cancer (see later).

Progress in the field of gene therapy has developed into two different strategies: ex vivo and in vivo gene therapy. The ex vivo gene therapy approach (combined cell and gene therapy strategy) involves the initial harvesting of cells from a given patient followed by genetic modification of these cells in the laboratory. The genetically modified cells can then be selected, amplified in numbers, and returned to the same patient in an attempt to achieve the desired therapeutic effect. This strategy is particularly attractive for the genetic modification of stem cells that could reconstitute the relevant tissues, organs, and organ systems after transplantation. The most prominent example is using hematopoietic stem cell grafts in gene therapy trials for hematopoietic disorders.

The in vivo gene therapy approach, in contrast, involves the delivery of the relevant transgene (through the use of various vectors) directly to the targeted tissue, followed by the stable or transient expression of the transgene in the relevant cells. The expression of the transgene only in the relevant cells/tissues can be achieved by a combination of localized delivery (injection), a particular tropism of the vector used for the tissue of interest, and the expression of the transgene under the control of a cell/tissue-specific promoter.

Gene Therapy Delivery Methods

Gene therapy agents are often composed of two elements: the genetic material itself (i.e., the DNA expression cassette [the most common therapeutic payload used], short interfering RNA, or an antisense molecule) and the vector delivery system. The latter is usually the more complex and limiting component, and it is important to select the most efficient delivery method for any genetic therapy as well as to be aware of the potential adverse effects of each vector type, thus tailoring the therapy to specific clinical considerations. There are formidable barriers to successful gene transfer, such as crossing the cellular membrane, escaping from the endosome, moving through the nuclear membrane, and integrating into the host genome. Vectors that have been developed to try to overcome these obstacles fall into two broad categories: nonviral and viral vectors.

Gene therapy mediated by nonviral vectors is referred to as *transfection* and consists of the direct delivery of naked DNA by injection, the use of liposomes (cationic lipids mixed with nucleic acids), nanoparticles, and other means. Although nonviral vectors can be produced in relatively large amounts and are likely to present minimal toxic or immunologic problems, their major shortcoming is inefficient gene transfer. In addition, expression of the foreign gene tends to be transient, precluding the application of nonviral vectors to many disease states in which sustained and high-level expression of the transgene is required. The efficiency of nonviral vector delivery could be enhanced by the use of different physical methods that have evolved, such as electroporation (for well-circumscribed body compartments or masses such as muscle, skin, and tumors), gene gun (for DNA vaccination), and ultrasound delivery (for cardiovascular and tumor-related applications).

Gene therapy mediated by viral vectors is referred to as *transduction*, and this approach has been the main conduit for transferring genes to human cells in most gene therapy trials. The basic concept of viral vectors is to harness the innate ability of viruses to deliver genetic material into the infected cell. Viruses used in gene therapy have been modified to enhance safety, increase specific uptake, and improve efficiency. However, for each specific virus-based gene therapy vector, there have been major disadvantages that should be balanced against potential therapeutic benefits. For example, in cancer gene therapy, the immune response to the delivery vehicle carrying the anticancer genetic material can be used to advantage by serving as an adjuvant. In contrast, the system for delivery of a gene to be expressed for a prolonged period to replace or supplement a missing gene product in monogenic disease states should preferably be ignored by the immune system.

Viral vectors are derived from viruses with either RNA (retroviruses and lentiviruses) or DNA (adenovirus, adeno-associated virus [AAV], herpes simplex virus [HSV], and poxvirus [vaccine virus]) genomes. Viral vectors also fall into one of two main categories: integrating vectors, which insert themselves into the recipient's genome, and nonintegrating vectors, which often (although not always) form an extrachromosomal genetic element. Integrating vectors, such as γ-retroviral vectors and lentiviral vectors, are generally used to transfect actively dividing cells because they are stably inherited. Integrating vectors, however, may carry the risk for insertional mutagenesis (with clinical oncogenic transformations reported with the use of retroviruses). Nonintegrating vectors, such as adenoviral vectors and AAV vectors, can be used to transfect quiescent or slowly dividing cells, but they are quickly (in the case of adenoviral vectors) lost from cells that divide rapidly. Finally, efficient gene transduction can also be achieved using vectors that are maintained as episomes, especially in nondividing cells.

Adenoviral vectors and retroviral vectors based on Moloney murine leukemia virus featured prominently in early gene therapy trials. There has been a movement away from both, however, after the case of a fatality, which was linked to the toxicity of the adenoviral vector (used to introduce the ornithine transcarbamylase gene in that specific study) and the leukemia cases in SCID-X1 patients (which were linked with activation of *LMO2*, an oncogene on chromosome 11, due to insertional mutagenesis associated with the murine leukemia viral vector). Consequentially, these vectors have been largely been replaced with AAV and lentiviral vectors, respectively, which have become the most common vectors used in clinical trials today. Other viral vectors may have applications in specific settings. For example, in gene therapy applications being developed for pain management, a replication-defective HSV vector is being used because of its tropism for nerve tissues. Also, different oncolytic viruses with a preferential tropism to cancer cells are being used for gene therapy applications in cancer.

Diseases Treated by Gene Therapy

Inherited Immunodeficiency

More than 30 patients reported to date worldwide have undergone treatment with different retroviral vectors for inherited immunodeficiencies (Chapter 250). Patients with one of the following three diseases are included in this group: two types of severe combined immunodeficiency (SCID), both of which are characterized by dysregulation of lymphocyte development, and X-linked chronic granulomatous disease (X-CGD), an inherited immune deficiency with absent phagocyte reduced nicotinamide adenine diphosphate oxidase activity caused by mutations in the *gp91* (*phox*) gene. Individuals with adenosine deaminase (ADA) SCID suffer from premature death of T, B, and natural killer (NK) cells as a result of the accumulation of purine metabolites; patients with this condition have been treated with vectors expressing the *ADA* gene. In the first patients with ADA SCID, transduced T cells expressing transgenic *ADA* have been shown to persist for longer than 10 years; however, the therapeutic effect of gene therapy resulted in incomplete correction of the metabolic defect. More recently, an improved gene transfer protocol of bone marrow CD34-positive cells, combined with low-dose busulfan, resulted in multilineage, stable engraftment of transduced progenitors at substantial levels, restoration of immune function, correction of the *ADA* metabolic defect, and proven clinical benefit.[12] Overall, no adverse effect or toxicity has been observed in patients treated with *ADA* gene transfer in mature lymphocytes or hematopoietic progenitors.

The X-linked type (X-SCID group), in which there is defective cytokine-dependent survival signaling in T and NK cells, was shown to be corrected by introduction of the wild-type sequence of the common γ-C chain, which is an essential component of five cytokine receptors. In one clinical study, hematologic malignancies developed in four patients. One of the four died of this complication. Ten patients were successfully treated with a different viral transduction protocol, with one reported malignancy in up to 8 years of follow-up. Two adult X-CGD patients who suffered recurrent bacterial infections have been treated with CD34-positive cells transduced with a γ-retroviral vector expressing *gp91 phox*, with significant clinical improvement in the

short term. However, in both these patients, there was an expansion of gene-transduced cells caused by the transcriptional activation of growth-promoting genes leading to myelodysplasia and gradual loss of efficacy. In summary, of the nearly 30 patients worldwide treated with gene therapy for immunodeficiency disorders, significant clinical improvement has been observed in many. However, severe and even life-endangering adverse consequences have been encountered with certain viral vectors and protocols. Additional clinical information from long-term observation and new clinical studies will be important for a clearer assessment of clinical benefit.[13]

Visual Loss

Both cell- and gene-based therapy approaches are leading areas for promising inroads in retinal disease. Although early trials of stem cell–based retinal cell therapy have not yet achieved proof of efficacy, at the level of gene therapy, clinical scientists have used gene augmentation therapy with direct subretinal injection of a recombinant AAV expressing *RPE65* complementary DNA in adults and children with Leber congenital amaurosis. This rare inherited eye disease destroys photoreceptors (Chapter 424), and the gene therapy results have shown medical evidence of visual preservation despite continued retinal degeneration.[14]

Cardiovascular and Pulmonary Conditions

Gene therapy efforts in the cardiovascular field have focused on achieving therapeutic angiogenesis in patients suffering from chronic ischemic heart disease or from critical limb ischemia (CLI) and for improving cardiac function in heart failure patients. The use of genes to revascularize the ischemic myocardium due to coronary artery disease and CLI due to peripheral artery disease has been the focus of two decades of preclinical research with a variety of angiogenic mediators, including vascular endothelial growth factor, fibroblast growth factor, hepatocyte growth factor, and others, encoded by DNA plasmids or adenovirus vectors. Overall, these gene therapy studies in animal experimental models of ischemia were very encouraging, leading eventually to several clinical trials. Despite the established proof of concept and reasonable safety, however, results of the latest clinical trials on therapeutic angiogenesis for myocardial ischemia and CLI have provided inconsistent results, and the definite means of inducing clinically useful therapeutic angiogenesis remain elusive. These less than optimal results may stem from a number of reasons, including the application of a single growth factor that may not be sufficient to meet the multifaceted challenge for developing efficient induction of collateral vessels, the need for more sustained growth factor delivery in order to establish more stable vessels, and the need to target arteriogenesis rather than angiogenesis to achieve a more significant increase in perfusion. Therefore, efforts in the field are moving toward the use of different cell therapies for these ischemic conditions, as well as using combined cell and gene delivery strategies to achieve better outcomes. For example, a recent trial has used combined delivery of endothelial and smooth muscle cells (each cell type modified to secrete a different angiogenic growth factor) in CLI patients.

For heart failure, gene therapy trials have focused on restoring the abnormal calcium handling characteristic of failing human cardiomyocytes.[15] Because a reduction in levels of the sarcoplasmic reticulum calcium ATPase (SERCA2a), the sarcoplasmic reticulum calcium pump, was found to be a key factor in the alteration of calcium cycling in heart failure, this protein became an attractive clinical target for gene delivery purposes. Overexpression of SERCA2a levels by cardiomyocyte gene delivery has led to the restoration of previously abnormal calcium transients and to improved cardiac contractility, reduction of the frequency of arrhythmias, and improved oxygen utilization in animal models of heart failure. More recently, the clinical benefits of overexpressing SERCA2a have been demonstrated in phase I and II of the Calcium Upregulation by Percutaneous Administration of Gene Therapy in Cardiac Disease (CUPID) trials. These studies demonstrated that AAV delivery of the SERCA2a transgene by intracoronary delivery is feasible and safe, results in persistent expression of the transgene, and is associated with a significant improvement in associated biochemical alterations and clinical symptoms of heart failure in the treated patients.

Cystic Fibrosis

Experimental protocols for gene therapy for cystic fibrosis (CF) (Chapter 89) have been implemented since 1990. The cystic fibrosis transmembrane conductance regulator (CFTR) protein is mutated in patients with CF. Transducing the epithelium of the nasal and bronchial tree is potentially feasible through nonsystemic approaches. Nonviral gene therapy methods that deliver a copy of the *CFTR* gene to the airway of CF patients have been developed. Several placebo-controlled clinical trials of liposome-mediated *CFTR* gene transfer to the nasal epithelium have confirmed its safety and demonstrated variable degrees of functional correction. In addition, several clinical studies have assessed the potential of retrovectors, adenovectors, and AAV vectors for gene therapy for CF. With both nonviral and viral delivery systems, there were only mild side effects. However, the long-term clinical benefit has been marginal. Improved vectors are being assessed in preclinical studies.

Cancer
